We see that the weight drawn increases as the root of the length, i.e., each added unit of length increases the draught, but to a less extent than its predecessor. If we double the length we multiply the weight drawn by $\sqrt{2} = 1.4$.

The weight of air drawn increases also with the temperature up to a certain point, but not indefinitely. It evidently reaches a maximum when $\frac{\sqrt{t_1 - t}}{1 + a t_1}$ is a maximum, which by differentiating and equating to zero is found to be when $t_1 = 2t + \frac{1}{a}$. If the outside

at freezing point $t_1 = \frac{1}{a} \therefore t_1 = 273^\circ \text{C}$.

and generally, the weight of air drawn is a maximum when the absolute temperature of the inner is twice that of the outer air, an easily remembered result.

The same temperature for maximum weight drawn is obtained if the actual velocity be taken as a constant fraction of the nominal velocity as calculated directly from the formula $v = \sqrt{2 g a L (t_1 - t)}$

Index I. This is important, because the actual velocities are always considerably below the calculated ones, owing mainly to frictional resistance and retarding effect of turns in the flues.

In a special case, let us take that in which the flues and chimney offer a negligible resistance compared with that of the fuel on the grate. We need only consider here the resistance of air through a highly resistant bed of material; the difference of pressure on the two sides would be the driving force, and would be the same as in the frictionless case, but S in formula (i.) (the cross-section of the chimney) would have to be replaced by a new constant A , equivalent area of the interstices of the fuel on the grate. With this alteration, formula (i.) is applicable, and the weight of air drawn is a maximum when $t = \frac{1}{2} t_1$.

This case is more nearly that of good practice; it is why even with ample flues and chimney the actual velocity and that calculated from (i) are not the same.

If the normal air temperature is 15°C. , $t = 15^\circ = 288^\circ \text{ Abs.}$ —i.e., the weight of air which a chimney can draw is greatest when the mean temperature of the gases in the chimney is $(288 \times 2 - 273)^\circ \text{C.}$ Here lies the strength and weakness of the chimney as an air mover. The idea is still very prevalent that the drawing power of a chimney rises continuously with the internal temperature. The velocity of gas in the chimney can be increased indefinitely by increasing the temperature (and the draught-gauge will show this increase, and so may mislead), but the weight of the gas diminishes at the same time, and it is at 273°C. that the weight of air drawn is greatest. At point I would, however, point out that the temperature of 273°C. is not that of the gas at the chimney which is the temperature easily determined, but is the mean temperature in the chimney; this temperature may be taken as the mean of the temperatures of gas entering and leaving the chimney, but it is not usually convenient to determine the latter.

The calculation as usually made for the loss of heat by any body allows separately for conduction and for convection losses; the formulae are complicated and not easy to apply to this case, even if at all applicable. If, however, we make the simple assumption of circulation of air round a chimney is sufficiently to maintain some temperature, say 40°C. on the surface, then the only calculation necessary is for amount of heat conducted through the walls of the chimney; radiation and convection are simply means of losing the heat so conducted, and do not enter into the calculation.

FIG. 3.

is the quantity of heat conducted per metre height of circular chimney, of external radius r and internal radius r_i , and if t_i is the temperature of the internal, t_e the external surface, then for an elemental ring of radius r and thickness dr :—

$$Q = -2\pi r C \frac{dt}{dr}, \quad C \text{ being the coefficient of conductivity}$$

$$\therefore C dt = -\frac{Q}{2\pi} \frac{dr}{r}$$

Whence, integrating between the limits r and r_i for r , and t_i and t_e for t

$$(iii.) \quad Q = \frac{2\pi r_i C (t_e - t_i)}{\log_e \frac{r_e}{r_i}}$$

the logarithm is to the natural base e .

If we take the specific case of a brick chimney of 1 metre internal diameter, and 0.25 metre thickness of wall, the mean internal temperature being 273°C. then

$$(iv.) \quad Q = \frac{880}{\log_e \frac{r_e}{r_i}}$$

$$\text{or } Q = \frac{44}{7} \times 0.6 \times \frac{273 - 40}{0.40} = 2200 \text{ kg}^\circ \text{C. units per metre of height per hour.}$$

0.6 is Péclet's mean value for C , the $\text{kg}^\circ \text{C.}$ units transmitted by 1 sq. metre surface of burnt clay 1 metre thick, for 1°C. difference, per hour.*

If we allow a velocity of 5 metres per second for the gases in the chimney (a good working velocity), then the

$$\begin{aligned} \text{Volume of gas per hour} &= 5 \times 3600 \times \frac{22}{7} \times (0.5)^2 \\ &= 11,140 \text{ m}^3 \text{ at } 273^\circ \text{C.} \\ &= 7,070 \text{ m}^3 \text{ at } 0^\circ \text{C.} \end{aligned}$$

$$\begin{aligned} \text{containing } 7070 \times 0.31 \times 273 \text{ kg}^\circ \text{C. units of heat} \\ = 600,000 \text{ kg}^\circ \text{C. units.} \end{aligned}$$

\therefore in this case the gas would lose—

$$\frac{22,000}{600,000} \times 273 = 1.00^\circ \text{C. per metre of height.}$$

If the chimney were 30 metres high, the loss would be 30°C. , and the mean temperature inside being 273°C. the temperature of the gas entering would be 290°C. nearly. The calculation may be a little simplified by substituting for (iii) the formula

$$(v.) \quad Q = C 2\pi \times \frac{\text{mean radius}}{\text{thickness of wall}} \times (t_e - t_i)$$

which is permissible if the mean radius is large compared with the thickness of wall.

The above calculation is made to illustrate the method; a simple application will show that the fall of temperature in a chimney may be very considerable if it is much too large for its work; to get a good draught in such a case would, of course, require a high entering temperature of gas to be maintained at the chimney base.

S. H. Davies (this J., 1904, p. 478) has made conductivity determinations for many insulating materials by a method very similar to the above, but in which he observes the actual temperature on the outer skin; unfortunately burned clay was not tested and I have, therefore, used Péclet's figure for the conductivity.

The general conclusion is that an average chimney-gas temperature of 300°C. , or say 320°C. entering the chimney is an upper limit of temperature which it is vain to exceed with the hope of drawing more air. It is not, however, to be regarded as a working standard, for a simple substitution in equation (i.) shows that the weights of air drawn diminish very slowly with falling temperatures in the chimney. Thus, if $t = 0^\circ \text{C.}$, the weights drawn with t_i 273°C. , 200°C. and 100°C. are as 8.25, 8.16, 7.4; i.e., with an average chimney temperature of 100°C. , the weight drawn is 90 per cent. of the maximum.

273°C. if outside air is at 0°C. ; 303°C. if outside air is at 30°C.

* Péclet's "Traité de la Chaleur." Third Edition, p. 406.

I do not propose to discuss the theory of the chimney further; it is so exceedingly difficult to take into account all factors in such a way as to arrive at absolute demonstration, but I venture the opinion that the result at which we have arrived in our brief, theoretical consideration of the problem, that nothing is to be gained by increasing the average temperature beyond 300° C., is quite in consonance with practice.

Good draught, then, can be got out of a chimney without sending into it excessive heat, and high chimney temperatures are aberrations of practice.

A very low temperature at the chimney foot is sometimes taken as a sign of economical working, but that may not be assumed, since an analysis of the flue gas will often show that the in-leak of air between the furnace and the chimney is the real cause of the lowness of temperature. The temperature and composition of the flue-gas should always be taken together if conclusions are going to be drawn. Buote's table (*vide* Appendix 2A) will then show the important number, the percentage of the original calorific power of the coal present in the flue-gases entering the chimney. Thus, assuming flue-gas from ordinary bituminous coal to contain 10 per cent. of carbon dioxide, and to enter the chimney at 200° C., $\frac{12.5}{12.5+50} \times 100 = 12$ per cent. of the heat of the coal is going up the chimney; 5 per cent. of carbon dioxide and 150° C. would show 17 per cent. waste. This test can, of course, be applied to a chimney serving a complete battery of boilers or furnaces, or both. I have calculated a similar table for use with Mond Gas (*vide* Appendix 2B).

We have seen to some extent the mode of action of a chimney, which is the only natural draught producer. Artificial draught is produced in a more obvious manner, by the direct suction of a fan, or in the case of what is called "forced draught," by the direct blowing of a fan or other air-compressor. Let us now consider the sort of draught most useful in several types of furnaces.

Most of the discussion on this question has centred on the steam boiler, and since it is so widely used an apparatus and is a very illustrative example, we can well take it first. In a steam boiler, the products of combustion are, immediately after their formation, at a temperature very much higher than that of the surrounding metal plates of the boiler; they give up heat quickly to the water through the plates; as they proceed they are cooled, and give up less and less heat to each unit of plate-surface; they still contain useful heat on leaving the boiler, and, consequently, are usually passed through an economiser, in which the feed-water is heated. (We are considering primarily the widely-used Lancashire boiler.) The economiser contains a great many pipes presenting in total a large surface in order to compensate for the fact that the cooled gases have not nearly the same excess of heat over that of the water to be heated as they had in the boiler. Supposing the installation is a good one, we may take the products of combustion as leaving the economiser at 150° C., containing 4–8 per cent. of carbon dioxide.

Is it better now to turn the products of combustion into a chimney, and so produce a natural draught, or to deal with them by a fan? What can we gain by interposing a fan? We might cool the gases further, and for that purpose add more economiser tube. But we realise that each set of economiser tubes added abstracts less heat from the flue gases, and if the addition is carried too far the first cost and up-keep of the tubes will more than balance the value of heat units saved. Moreover, if the products of combustion are too cool, the sulphur acids condense on the cooler iron of the economiser tubes, and cause a fall in their efficiency more or less rapid and an ultimate destruction, with possible danger and certain expense. Such a deposit on analysis proved to be essentially a mixture of ferrous and ferric sulphates. Apart from the action of sulphur gases, there is also a deposit of moist sooty matter on over-cooled economiser tubes. The limit to the advantageous adding of tubes is acknowledged by the economiser makers; 400° F. (204° C.) is sometimes given as a temperature of gases leaving boiler,

below which it is of no use to add economiser tubes. makers also rightly insist on the economiser being with warm water; the effect of cold water inside economiser pipes is, of course, to cause condensation cooled products of combustion on the outside. It is to be noted that the cooling and condensing may be and usually is so, the large cross-section of economiser flues being favourable thereto; it is not sufficient to ensure that the average temperature of the products of combustion is a safe one; no part of the economiser top, bottom, or sides, should show the presence of at a dangerously low temperature; this is a point of some importance in practice which may be easily missed. It appears, then, that cooling of the gases below a certain point, say, 150° to 200° C., is not to be regarded as an advantage, and so we may say that if a chimney already exists, and has the drawing power required of it, there should not be put in. A calculation can be made which shows that the efficiency of a chimney as an air-mover is appallingly low; such a calculation has been published as showing the great advantage of using the much more efficient fan; it is quite plain, however, that in the case of a chimney using gas at 200° C., and a fan driven with gas at the same temperature, the chimney is utilizing a very small proportion of the heat, but the fan not at all (for it has to be driven independently); that the difference between them. Suppose, however, that the chimney does not already exist, then the short smoke-stack which is sufficient for the fan-draught offers a considerable saving in cost, even when the cost of the fan is considered. Or, suppose that the draught power is insufficient, that the flues or the chimney are not sufficiently capacious, we can use the full draught of a chimney with economy certainly, but cannot increase it in any reasonable way; the addition of a length to the chimney may be of some use, but such a piece of work is usually done at great disadvantage, and, as has been noted, each additional foot does less than its predecessor. Or, suppose that the fuel is of low quality, and will not burn in a fierce draught, or, again, that it is desired to increase the output beyond the normal, the full natural draught being already applied. Then we recognise that air can be drawn or forced through the fuel and flues at a greater speed than the chimney can give, and that the aid of a fan. A damper can be used to secure accurate control just as with a chimney, and the power used is very small (say, 1 per cent. of the steam raised) and the attendance almost *nil*. The fan here finds its legitimate function.

Let us compare the natural and forced draught more closely. A boiler is much more likely to work efficiently if the combustion is effected without a large excess of air. Thus, if the gases leave the economiser at 200° C., containing 8 per cent. of carbon dioxide, 15 per cent. of the heat of the coal is wasted in them; if they contain 4 per cent. of carbon dioxide at the same temperature the waste is 28 per cent. The best way to diminish the excess of air, while maintaining active combustion, is to work with a thicker fire, but the thicker fire offers more resistance to the passage of air, and to overcome the resistance effectively often means more air-pressure or draught than a chimney can give. The use of very low class fuels this high pressure is an absolute necessity if they are to burn at all, and probably it allows a smaller excess of air to be used. On six Lancashire boilers side by side, working into the same chimney, one with a fan-made air-pressure of 5 cm. water-gauge (the grate and the others with 15 mm. draught on the flues), observations were made as to coal burned per sq. ft. of grate area and composition of flue gas. The advantage in output lay greatly with the forced draught; the fan-burned averaged 21 lb. per sq. ft. of grate per hour, as against 15 lb. for the natural draught. In composition of flue gas the differences shown were small so long as the samples at the hand-fired natural draught boilers were taken while the firing doors were closed. The following table illustrates this; the figures are strictly representative of normal working:—

Description of Boiler.	No. of Boiler.	Minutes sampling after firing.	Sample drawn.	Analysis—Flue Gas.		
				CO ₂ .	O.	CO.
Hand-fired Lancashire draught...	1	2	Leaving furnace flue.	12.8	5.6	6.0
	2	4		15.1	3.2	6.0
	3	7		14.8	3.5	6.0
	4	10		14.6	3.1	6.0
	5	12		13.7	4.8	6.0
Mechanical stoker with forced draught....	6	—	Leaving furnace flue	15.1	2.8	6.0
	6	—		14.8	3.2	6.0

NOTE.—The grate area in the case of forced draught included side dead-plates; the consumption of coal per sq. ft. of effective grate area was considerably higher.

The average amount of free oxygen in many tests was 5 per cent. for the forced draught, 4.0 per cent. for the hand draught, indicating about 30 and 40 per cent. of air used in the two cases. All these samples were taken leaving the furnace flue at the back of the boiler. I think that the erratic numbers which find their way into conversation and print regarding the amount of carbon dioxide and oxygen in the flue-gases from boilers are very largely due to sampling at the wrong place. With a good new boiler-setting the errors from this cause are considerable, and with an old or bad one almost inconceivably large. I give examples (Lancashire boiler):—

Sample drawn.	CO ₂ .	Per Cent. in Flue Gas.				Remarks.
	<i>a</i>	<i>b</i>	<i>c</i>	<i>d</i>	<i>e</i>	
Leaving furnace flue	15.2	14.8	14.4	—	4.8	<i>d</i> was the mean of 5 determinations for a gas-fired boiler, newly set.
From front	8.6	8.4	8.2	14.9	11.2	
From side flue	5.9	6.2	—	—	—	<i>a</i> and <i>b</i> are averages—setting 10 years old.
From economiser	—	—	—	11.5	—	

Chemical analysis is to be used as a positive means of control in boiler firing, the necessity for caution in this is obvious; samples should be drawn as soon as possible after the completion of combustion, before there is a chance to leak in and make the sample tell a false tale about the combustion process; if the sample is drawn too near the fire, the presence together of carbon dioxide and oxygen discloses the fact. In a Lancashire boiler a good sample can be drawn at the back, where the gases leave the furnace flues. Of course, if the idea is to determine the percentage of total heat escaping in the gases (before or after economiser) the sample must be taken at the leaving-point and be coupled with a simultaneous temperature determination at the same point. In the comparison made above, the results of gas analysis would be less favourable to the hand-fired boiler if we were to take into account the very low percentage of carbon dioxide at the time of firing, when the doors are open, but this is not caused by using natural draught but by using hand-firing. I think we may say that the comparison leads to the conclusion that there is a great advantage in the forced draught, inasmuch as a high output was easily maintained, combined with a satisfactory combustion ratio of carbon dioxide to oxygen in the flue gas.

There is a caution to be given here respecting the use of a fan for the sole purpose of enlarging output; the hand and economiser have a heat-absorbing power which can be increased by apt use up to a certain point, but which is none the less limited, and a fan so used as to draw more coal on the grate than this limit allows, is in a wasteful fashion; such waste is pointed out in the case of excessive temperature in the escaping flue gas. The high temperatures developed by rapid combustion under forced draught, make the construction of the grate and the method in which the fuel is to be burned, and from the clinker is to be removed, also a very important matter. The temperature of the fire can be kept down by using a steam injector to suck in air, and discharge it under the grate, mixed with steam. There can be no doubt that in this way low-class fuels

can be burned so as to raise steam, but weird stories are in circulation as to the proportion of the steam required to work the injector. I have made no tests.

It may be worth noting that since the special usefulness of a fan is to create a high velocity against resistance on the grate, it follows that in a gas-fired boiler, the fan is not called for; in this case there is no bed of fuel and, therefore, the resistance is low, and much larger quantities of gas than of coal can be burned with the same draught. There is here the further reason that whereas the stopping of a fan for a few minutes in itself checks combustion in the coal fire, it only checks the air supply to a gas-fire, and large volumes of unburnt gas stream through the

flues until the attendant turns off the gas supply; this may be a serious danger, especially at night. (The gas is supposed to be supplied under pressure, as from a modern producer-gas or blast-furnace plant.)

We will now consider briefly other types of furnaces. Perhaps the simplest of all is the ordinary reverberatory furnace, of which the iron-puddling furnace and coal-fired reheating furnace are samples. The coal burns on a grate, and the products of combustion pass at once into the working part of the furnace, and there heat the iron or other material; they then pass to the chimney. This is the ordinary construction, and since the gases reach the chimney at nearly the working temperature of the furnace, their temperature is obviously too high for a fan. And not entirely because no quick-running machine can withstand the heat and oxidation satisfactorily for any length of time. Even if that difficulty were overcome the increased volume of the gas resulting from its high temperature would be a hindrance. If the temperature of gas is 819° C., the fan to draw them must have twice the capacity; if 1365° C., three times the capacity, which would be necessary for the same gases at 273° C. A pressure-fan delivering air under the grate would be more applicable, and a steam jet blower is sometimes used. The furnace may be arranged so that the products of combustion are utilised in a boiler on their way to the chimney. This is a very efficient arrangement if well designed, because the steam-boiler is such a capital heat abstractor and the steam is nearly always wanted at hand. The conditions in general governing choice of draught become in this case those of boiler-firing previously discussed.

The furnace or kiln ordinarily used for the firing of bricks and pottery is really a reverberatory furnace, in which the volume of the goods to be heated is very large in relation to the grate area. Consequently, until the temperature inside the kiln becomes high, the products of combustion are cooled by giving up heat to the goods, and the flue-gases are cool; when the higher temperatures are reached inside the kiln the hot goods have very little heat-absorbing power, and so the flue-

gases escape hot. Here we have a peculiar case in which the products of combustion increase continually in temperature and volume as the firing progresses; it is much better suited for a chimney than a fan. The conditions are different in a kiln of the continuous type which we will now consider, taking as our example the continuous brick-burning kiln as introduced by Hofmann.

In this type of kiln the coal is consumed in direct contact with the bricks; it is usually fed down through small round holes in the kiln top and, dropping among the bricks, burns there. The air which burns the coal is heated by coming through cooling bricks behind, already baked; the products of combustion pass forward and heat up the unbaked bricks in front until these products of combustion are so far reduced in temperature that they would deposit moisture if cooled any further; they are then taken out through a damper into the main flue and so to the chimney; the kiln is divided into chambers, usually about sixteen, and each chamber has a damper of its own, opening or shutting the way into the main flue. As will be readily understood the temperature of flue-gas can be reduced in this case to a point such that the products of combustion will just not deposit moisture on the bricks; the draught is small, therefore, and very high chimneys are usually provided for these kilns. The use of a fan would be good practice, and indeed the fan is coming into use, more particularly in new plants, where the saving of the first cost of a high chimney is desired. The effect of increasing the draught by means of a fan is interesting to follow.

In the accompanying figure (IV.) the dotted line marks the assumed distribution of temperature along the length of the kiln when the chimney is producing the draught. On putting a fan into use and raising the draught the quantity of air drawn is increased, and in order to neutralise the cooling effect of the excess of air the rate of feeding-in coal must be also increased. Two effects follow; in the first place the temperature curve is flattened; this necessitates more chambers in use, and shows us that the usable draught is limited by the number of chambers in the kiln. In the second place the peak of the temperature curve travels more quickly along the kiln, the chambers are burned more quickly, and the output increased. The increase in output can be effected with economy by increasing the draught until the limit is reached which the size of the kiln determines; beyond this, higher draught means waste of fuel; it would then be usually wrong to apply a fan to increasing

the output of a kiln which has already as few chambers as will work well with natural draught, but increasing the draught up to the maximum determined, economy is effected, and this because, a from increased output from the same plant which increases the commercial efficiency, the radiation and conduction losses from the kiln remain constant, and so can be made to bear a smaller ratio to the total thermal units of combustion.

So far as regards regenerative gas-furnaces, with ordinary construction, the gases leave with quite enough heat in them, 200–400° C., to work a chimney well; the remarks applied to the gas-fired boiler are also applicable here, but to a less extent.

Enough has now been said, I think, to indicate the of question which must be answered before a rational choice between natural and artificial draught for specific purpose can be made. The exact form question and answer take is dependent on very many factors. Finally, let me say that I cannot feel that I have treated this large subject in any adequate fashion, but can only have approached it without prejudice, and not without some experience.

APPENDIX I.

The formula (i) is derived thus:—

$v = \sqrt{2gh}$ where v is the velocity of gas in *cea*, Fig. 1, hot column.

h = the head producing motion.

g = the force of gravity.

Now $(L+h)(1+at) = L(1+at_1)$

where L = height *ab* (chimney height)

a = co-efficient of expansion of air, $\frac{1}{273}$
 t = temperature of column *cd* (outside temperature).

t_1 = temp. of column *ab* (inside-temperature).

$\therefore h = La(t_1 - t)$

$1 + at$

or, since a is so small,

$h = La(t_1 - t)$

$\therefore v = \sqrt{2gLa(t_1 - t)}$

But $Q = svlt_1$

where Q = weight of air in unit time.

s = cross-section of *ab*.

d_1 = density of air at temperature t_1 .

$= Sv \frac{d_0}{1 + at_1}$

where

d_0 = density of air at temperature 0° C.

$\therefore Q = Sd_0 \sqrt{2gLa(t_1 - t)} \quad (i)$
 $1 + at_1$

APPENDIX II.

A.—BUNTE'S TABLE.

For Calculating the Per Cent. Loss of Heat from Fuel Gases. Coal = C. St = S; H. 5.43; O. 8.18; S. 1.16.

Percentage of CO ₂ in Flue Gases.	Capacity for Heat in Cals. of the Flue Gases = C.		Initial Temperature °C. (W)		Difference for 0.1 Per Cent. of CO ₂ .	Cb. ft. of Gases per lb. fuel at 62° F.

16	0.325	0.00920	2130	2366	—	160*

* The 7th column is added by Fletcher.

1 lb. ft. of carbon dioxide is formed by combustion 23 cal. are evolved. The quantity of heat (=W) is divided from the per cent. CO_2 is divided by the capacity of 1 lb. ft. of the chimney gases. The result gives the so-called initial temperature (T).

Use this Table:—If T = the initial temperature and t = the difference between the exit temperature of the flue and the temperature of the air supply then $\frac{t}{T}$ expresses the ratio of the heat lost through the escaping to the heat developed.

The following table is calculated for works using Mond gas as the fuel employed, and has only the degree of accuracy necessary for that purpose. A mean capacity of 0.34 per m³ of combustion products is used; the Bunte numbers are, of course, too low. The rapid specific heat of carbon dioxide and water with temperature makes it necessary to calculate separately for use if a high order of accuracy is demanded. The table is only scientifically correct for products of combustion containing 9 per cent. CO_2 at 600° C., and the results increase as the actual conditions differ more widely from these. The numbers of MM. Mallard and Le Chatelier are taken for the specific heats. The gas is supposed to be an average sample of Mond gas saturated at

15° C. with a calorific power of 1,200 kg. C. unit per m³, the products of combustion being supposed cooled to 0° C. without condensation.

It is interesting to note that the table is applicable to determine the percentage of the total heat of gas escaping in the exhaust of a gas-engine.

To Use the Table:—

If T is the initial temperature (nominal) of combustion and t is the difference between the exit temperature of the waste gases and the temperature of the air supply, then $\frac{t}{T}$ expresses the ratio of the heat lost through the escaping gases to the heat developed.

T was calculated in constructing the table by dividing the kg° C. units in 1 m³ of the products of combustion by 0.34.

The per cent. of carbon dioxide is the percentage as determined by ordinary gas analysis.

The excess air per cent. is the excess over that required for theoretical combustion.

GAS-FIRING TABLE.

DISCUSSION.

A. SMITHIELLS said Mr. Cobb's paper was a very valuable contribution to an important subject, which had been very much neglected. Merely from the theoretical point of view, it would form a good problem in elementary physics. Text books and engineering treatises gave the subject little consideration, and a student working at a laboratory or engineering might become highly educated without gaining much knowledge of it. Even engineering students showed remarkable ignorance on these matters. It is a reason he hoped the paper would have a good circulation and attract attention, which was fortunately the case when it came to be printed in the Journal.

LEACH asked if Mr. Cobb could explain the big difference in the percentage of carbon dioxide present in the gases leaving the flue (14 per cent.) and gases leaving the boiler (4–5 per cent.), as it was almost impossible to find a large difference could be due to air leakage in the

T. FAIRLEY said he had had some experience in the use of destructors, where the only object was to burn a fuel as completely as possible. The temperature at the bottom of the chimney stack was higher than the temperature at the top. Mr. Cobb recommended. He had analysed the gases and found a certain amount of leakage between the bottom and the top of the chimney. In complicated

apparatus this was unavoidable. By the use of a steam injector a hotter fire might be obtained. Possibly in such a case the chimney might be dispensed with and a form of blast furnace substituted, in which the steam used and the higher temperature would both tend to greater efficiency in a destructor.

Mr. COBB, in reply, said he did not consider that the paper brought forward the theoretical side of the subject too prominently, as he had always found that a proper understanding of theory was the best way to arrive at practical results. He thought that leakage between the boiler and far end of the economiser caused the difference in percentage of carbon dioxide in the gases leaving them. Considerable leakage took place at the damper, and samples of gas should therefore be taken on the boiler side of it. When an economiser was working for several boilers, one of them might be firing up when a sample was taken. The economiser was usually so constructed that an enormous brickwork surface was obtained, and this always caused leakage of air. The tubes of the economiser required to be cleaned by the use of scrapers, with chains attached, working inside holes in the outer casing, and this also involved leakage. This leakage of air lowered the temperature as well as the percentage of carbon dioxide, and might lead to a misapprehension, if the fall of temperature alone in the economiser was assumed to indicate its efficiency. It was a mistake to have the tem-

perature at the base of the chimney too high, as in the case Mr. Fairley mentioned, with the idea of gaining in draught. An attempt to lower temperature might be made by the interposition of boilers between the chimney and economiser. A steam injector would usually produce a higher temperature in the fire, because it supplied more air, and so led to more rapid combustion, but not high as if a fan were used, supplying the same quantity of air as the injector.

Meeting held at Bradford on Monday, March 20th, 1905.

PROF. PROCTER IN THE CHAIR.

OLIVE OILS AND THE FREE OLEIC ACID QUESTION IN WOOLCOMBING.

By F. W. RICHARDSON AND ADOLF JAFFÉ.

During the past twenty years there has gradually grown up a belief that the oxidisability or gumming property of an olive oil is in direct proportion to the amount of free oleic acid it contains, and thus it is that so many free acid tests are made, and oils of even widely different sources are graded upon the free oleic acid figures. We would indicate what we believe to be the best method for estimating free oleic acid in oils, and we do this because at least one of the methods in vogue is slow in its application and unsatisfactory in its results. Some years ago we had a dispute as to the actual percentage of free oleic acid in an olive oil. On repeating our estimation, we always obtained the same figures, so also, we were told, did the other chemist. We found that this gentleman used methylated spirit as his solvent and titrated with aqueous caustic potash, using phenolphthalein as indicator, of course; at our suggestion, the potash was tested for carbonate, which was abundantly present. As the alkali had been standardised with normal sulphuric acid and methyl orange indicator, the chemist will readily perceive where the error arose, phenolphthalein being neutral to bicarbonates while methyl orange is alkaline. We purify methylated spirit by distillation and redistillation with caustic potash and soft soap, and find that the distilled product enables us to obtain a practically colourless half normal caustic potash. To make this solution and to exclude carbonates as much as possible, we commence operations by using a very concentrated and clear solution of caustic potash in strong alcohol, and dilute this with the special spirit to the strength required. In an oil flask we weigh 10 grms. of the oil and dissolve in about 40 c.c. of neutral ether, add slightly alkaline tincture of phenolphthalein and titrate with recently standardised alcoholic potash of about half normal strength. What stress must be laid upon the free oleic acid factor in olive oil analysis? If oleic acid is more readily oxidisable than the glyceride from which it has been obtained, i.e., if it can be more easily transformed into a species of varnish when exposed in shallow layers to the action of the air, more than a certain per cent. of it in an olive oil intended for woolcombers use must be objection-

able. When an oil is distributed over the surfaces fibres, it is clearly in the best form for undergoing oxidation. J. Dugast in "L'Industrie Oléicole" (page 1) gives some data, showing that after 100 grms. of oil have been kept in contact with 700 c.c. of air for nearly a year in a closed flask, about half the oxygen of the was absorbed by the oil and some carbon dioxide formed; meantime there was a distinct increase in acidity. Mackey has devised a very useful piece of apparatus for testing the heat developed by oils when they are distributed over cotton waste surrounded by a vessel containing boiling water; the more readily an oil absorbs oxygen the higher will be the temperature developed; therefore, the temperature-increase is a measure of oxidisability, and at the same time of the tendency to form varnish-like bodies. Mackey (Lewkowitz Chemical Technology, &c., of Oils, Fats, &c., third Vol. 2, page 958) has found that a 97 per cent. "oleic" i.e., an oleine containing 97 per cent. of free fatty acid calculated as oleic acid, after 1½ hours in his apparatus attains a temperature of 216° F., while under the same conditions an olive oil with only 1 per cent. of free fatty acids gives as much as 219° F., and four other olive oils gave temperatures from 214° to 416° F.; on the other hand three olive oil fatty acids gave in 1½ hours from 271° to 351° F. This would seem to show, that although commercial oleic acid, i.e., "oleine" is not a particularly oxidisable body, yet the same cannot be said of the fatty acids obtained from olive oil, which would appear to oxidise in some cases as much as cotton oil. Our experiments confirm Mackey's as far as the comparatively low oxidisability of commercial oleic acid is concerned. We used cotton fly waste in comparison with silk waste in some experiments, and obtained the following figures in Mackey's apparatus:—

Temperatures °F. obtained with

	Cotton Fly Waste.		Silk Waste.	
	1 hour.	2 hours.	1 hour.	2 hours.
Cotton oil	220	400	262	over
10 per cent. cotton oil	—	—	215	—
95 per cent. olive oil	—	—	209	—
5 per cent. cotton oil	—	—	208	—
95 per cent. olive oil	202	205	208	—
Olive oil	—	205	—	—
Oleic acid (98 per cent.)	—	—	—	—
Price's	—	—	—	—

Here we found the oleic acid gave the lowest temperature on silk waste (after two hours) of any of the trials. We have been repeatedly assured by Bradford and district oil trade experts, that the class of olive oil, also the character of the season and crop are far weightier matters than the oleic acid factor, which is of comparatively little importance. In commencing our experiment we allowed air to bubble through 200 c.c. of the oil heat in conical flasks to 210° F. for 40 hours, and then ascertained viscosity and other features characteristic of change to oxidation.

The following are some of our results:—

OLIVE OILS.

	Gallipoli Oils.			Malaga Oil.	Seville Oil.

Seville oil with low percentage of free oleic acid even unsatisfactory results on wool, and from the aints made, it was evident that this oil had oxidised erably and had produced a stickiness and semi-like result on the fibres. The Gallipoli oil with the percentage of acid, six times that present in the oil, had given excellent results on wool; the uniform with Gallipoli oils; even with those containing high stages of free oleic acid. In a paper upon "Lubricating Oils" by one of us and H. Norman Hanson (as J., 1905,) we indicated a method for testing oils (dising at 212° F. or 400° F. in shallow layers, and ve an illustration of the apparatus used. We also ed a simple 5 c.c. viscometer which has enabled us rk with small volumes of oil and to obtain very agreeing results. Shallow layers of the two oils e wish to compare were submitted to a current of 212° F. for six hours, with the following interesting gnificant results:—

	Viscosities at 210° F.		Butyro-refractometer at 19° C.	
	Before Oxidation.	After Oxidation.	Before Oxidation.	After Oxidation.
olive oil F. free acid) ...	43	47.5	63	64

ge of increase of viscosity						
oxidation for four hours at						
F.	73	—	644	407	315	215

Seville oil shows nearly nine times as great an of viscosity as the Gallipoli oil under exactly the nditions of exposure to hot air. The fatty acids eville oil and Levant olive oil show only two-thirds osity after oxidation of the oils themselves similarly Quite an unexpected result. It may be urged 2° F. is a very high temperature to use—this we but even 212° F. required for Mackey's test, is the normal temperature of the atmosphere, and

we have proved that, whether we use 212° F. or 400° F., the oxidation products obtained are in general the same as those produced at lower temperatures. Our 400° F. test certainly gives a good idea as to the readiness or otherwise with which an oil or its fatty acids will become viscous and finally varnish-like on exposure to air. If 400° F. does produce abnormal effects as far as fatty acids are concerned, it should be in the direction of increased, rather than decreased, viscosity as compared with the neutral oils, because the fatty acids certainly lose much more weight and suffer a loss of some of their more volatile and doubtless less viscid constituents. The heating effect developed on cotton or silk waste when the oil and fibre are heated together at 212° F. does not run parallel with the increase of viscosity as far as concerns olive oils when tested in comparison with their fatty acids; although in general the drying tendency of an oil, e.g., linseed oil, is indicated by this process.

It may be urged that the Seville oils contained a larger proportion of unsaturated fatty acids other than oleic acid, e.g., more linoleic and linolenic acids, &c.; if this were so we should expect to see it reflected in a proportionately higher iodine number; but this was not the case. We are forced to the conclusion that olive oils are very much more complex than has commonly been supposed. At all events it is much easier to try the oxidation test we have suggested than to proceed to separate and estimate the fluid fatty acids present, and obtain their bromine or iodine numbers. The changes which take place when a vegetable oil is oxidised are:—(1) Increase in viscosity with the final production of solid varnish-like bodies. (2) Increase in refractive index. (3) Increase of the melting point of the fatty acids. (4) Decrease of the iodine number.

These changes are always found in oils recovered from tops by means of solvents, and furnish data of a perplexing character to the analyst who is requested to make an examination for cotton or some other seed oil. In a typical case we found the following results:—

	Iodine No. Per Cent.	M. Pt. °C. of Fatty Acids.	Refractometer at 49½° C.
Oil recovered from wool tops	52.0	35.5	48°
A pure edible olive oil	83.0	27.0	39°
A ditto after oxidation for 2 hours in shallow layers at 400° F.	50.39	36.5	44.5

These figures show that one has accomplished in two hours much the same changes that have resulted from the exposure of olive oils on tops for several weeks; thus the process is absolutely in line with the changes which occur on atmospheric exposure.

The conclusions which we deduce from our observations and experiments are:—

(1st.) The mere percentage of free oleic acid in an olive oil is no very reliable guide as to the suitability or otherwise for oiling wool.

(2nd.) The neutral portion, constituting by far the largest bulk of the oil, is worthy of more consideration than the free oleic acid factor.

(3rd.) Oil importers of large experience are right in their assumption that it is the whole character of the oil, and

the nature of the source and the crop which are of far more importance than the free oleic acid factor.

(4th.) To decide whether an olive oil will produce sticky and varnish-like results when applied to wool one has only to oxidise in shallow layers at 400° F. and obtain the increase in viscosity. This datum, in comparison with figures obtained under the same conditions with standard oils of well-known excellence, should furnish a reliable guide as to the value of the oil in question. We do not wish to set aside such factors as the colour, odour, and taste, but these require long experience for their satisfactory determination and are more reliably determined by the commercial oil expert than by the average chemist.

DISCUSSION.

Mr. WILLIAMSON said that years ago Gallipoli olive oil was of a superlative quality, and contained only a small amount of free oleic acid. During the last ten years the proportion of oleic acid had increased considerably, owing to deterioration of the olives by the ravages of a certain fly. There was, however, no deterioration in quality, and no complaints had been made by buyers, even in oils containing as much as 10 to 14 per cent. This showed that it was not advisable to attach too much importance to the free oleic acid present. The best oil was probably Gallipoli, then Cretan, and then possibly Málaga oil from Spain. Excellent oils were obtained from Greece and the Ionian Islands, but the growers did not take sufficient care in the cultivation.

Mr. VINT, speaking from a consumer's point of view, said he had changed his opinion within the last few months, and now thought that oils which gave low acid tests were not necessarily the best for woolcombers. The chief requirement was an oil which would not oxidise or increase in viscosity. Free oleic acid was only injurious because it might set up corrosive action on the metal parts of the woolcombing machinery. He preferred good Gallipoli oil, such as last year's supply. Could something be done to remedy the ravages of the fly which Mr. Williamson said had caused the increase in acid in Gallipoli oil? Sound Gallipoli oil with low percentage of free oleic acid was always preferable to same oil with higher acid test.

Mr. W. McD. MACKEY said that his apparatus was originally intended for testing oil for insurance purposes, but he was pleased to find that Mr. Richardson had been able to make use of it in his work. The paper and discussion seemed to show that users of olive oil in Bradford had got back to where they were before the acid value had come into prominence as a test, which said something for the value of what were often called rule-of-thumb methods as opposed to analytical.

Mr. W. RUSHBY said he understood that the chief disadvantage of the presence of oleic acid in olive oils was the discoloration of tops which it caused, due to small quantities of metal which dissolved in the acid, and which set up secondary changes in the oil. Was it not a fact that Belgian oleine, consisting chiefly of oleic acid, was being used for woolcombing?

Mr. T. FAIRLEY had tested oils for oxidation on the surface of wool, and found that oleic acid sold as "oleine" compared favourably with other oils. An important point to notice was that the amount of free acid increased in oils on prolonged keeping.

Mr. W. M. GARDNER stated that the discoloration of tops was more likely to occur by the use of olive oil containing free oleic acid, and this was probably caused not by the oleic acid itself but by decomposition products.

Mr. C. W. SLATTER said that woolcombing experts objected to the presence of free fatty acids in oils. He agreed with Messrs. Richardson and Williamson in preferring Malaga to Seville oil. How would Mr. Richardson recognise mixtures of olive oil, with olive oil extracted by carbon bisulphide? He agreed that oleic acid would be injurious to brass and metals. Did Mr.

Richardson refer to adulterated oil when he spoke of defective olive oils? He advised caution in accepting new methods of testing, and would not throw over the ideas without due consideration.

Mr. RICHARDSON, in reply, said he considered Malaga oil second only to Gallipoli oil, since it was excellent rule. Very little Cretan oil came to this country. In the past 20 years, in Bradford, he had never known browned by Gallipoli oil containing even over 20 per cent of free acid. With regard to oils extracted by carbon bisulphide, samples which he had at first thought adulterated, owing to the peculiar results obtained testing, afterwards proved to be genuine. The distinguishing feature of "sulphur" oils was the black with silver nitrate and the orange colour produced by mercury nitrates.

Obituary.

JULES KOLB.

OFFICIER DE LA LÉGIION D'HONNEUR. DIRECTOR OF THE FIRM OF KUHLMANN AND CO. MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

Jules Kolb was born in Strasburg, July 2, 1837. After a course of study in the Lycées of Strasbourg and Algeria, he entered the Ecole Centrale in Lille, leaving it in 1859, with high honours, to become chemist of the firm of M. Kuhlmann, in whose service he continued in various capacities for the rest of his life. After a year as chemist, M. Kuhlmann advanced him to the position of manager of the Amiens branch of his business. With indomitable energy, the young director applied himself to his new duties, as also the solution of numerous technical problems. In 1861 he was one of the founders of the *Société Industrielle d'Amiens*, and in its Proceedings most of his subsequent investigations appear. Of this Society also he was Vice-president from 1870 to 1873. In 1865, the *Faculté des Sciences de Lille* conferred upon Kolb the degree of doctor, on the presentation of his remarkable thesis on "*The Reactions in the Manufacture of sulphuric Acid*." In 1870, he was nominated to membership of the *Académie des Sciences, Arts, et Lettres*, of Amiens, and in 1872, he became the president of the *Société Industrielle de Mulhouse*, in consequence of his Memoir on the specific gravities of Commercial Sulphuric Acid. In 1881, M. Kuhlmann died, and Kolb was chosen to fill the vacant place of practical director of the firm. In 1883, he wrote the articles on the chlorides, phosphates, superphosphates, for *Fremy's Encyclopædia*, and in 1884, he was called to be the Director of the Lyceum. In 1885, Kolb entered the Society of Chemical Industry as a member, and so continued until shortly before his death. In 1886, he was decorated by the *Académie des Sciences*, and the Montyon prize awarded him for his Researches in connection with "*Improvements introduced into Chemical Industry bearing upon Sanitation*." M. Kolb was also elected President of the Society of Political Economy, Statistics, and President of the "*Comité de l'Ecole des Beaux-Arts et Conservateur des Musées Industriels et Commerciaux de Lille*;" in 1894, he was nominated "*Inspecteur Départemental de l'Enseignement Technique*," and in 1895, was further created "*Officier de la Légion d'Honneur*," and the *Société Industrielle* awarded him the Founder's (Kuhlmann) gold medal.

Jules Kolb died April 18, 1905, at Lille.

PLANT, APPARATUS & MACHINERY.

ENGLISH PATENTS.

Apparatus; Impts. in —. B. Hoffbaur, Cologne. Eng. Pat. 7739, March 31, 1904.

paratus, several forms of which are described and is arranged so that the drying chamber is divided o parts, through which the material to be dried d successively. A current of air passes through :or preliminary drying chamber, and after effecting oval of a portion of the moisture passes direct to 2. Another current of air is sent through the chamber and completes the desiccation. This air carries away with it much dust or fine material, first through the partially dried substance in the ary drying chamber, in order that the dust may ed by the partially dried material, and then to .—W. H. C.

Churning, Concentrating or Drying of Semi-uid or Viscous Materials, and Apparatus refor. J. S. Beeman, London. Eng. Pat. 8600, cil 14, 1904.

es are mounted so as to rotate in opposite directions. es overlap and are so adjusted that the distance i their flat sides is just sufficient to cause a thin e material to be dried to form between them. erial, which may be fed on to the discs by any means, also forms a "curtain" or connecting een the discs. To facilitate drying, the surface ilm may be broken up by a scraper. The dried i is removed by another adjustable scraper which brought into operation as required. The drying promoted by enclosing the apparatus in a casing, which a current of air is caused to flow.—W. H. C.

Solid Materials or Crucibles, Pans, Retorts, the like, containing Solid or Liquid Materials. Gas; Impts. in —. L. C. Reece, London. g. Pat. 10,094, May 3, 1904.

ssel to be heated is supported on perforated bricks is in the furnace and surrounded by broken refrac- terial, leaving sufficient space between the pieces ater, to allow room for the gas and air to enter and und for the products of combustion to escape. gs are left in the furnace casing for the gas-supply e waste-gas flue and for the introduction and t of the crucible or other vessel to be heated. nace casing is surrounded by an annular jacket, i which the air necessary for combustion may ed in order to preheat it.—W. H. C.

Vaporising Apparatus; Impts. in —. L. E. Vial, Brussels. Eng. Pat. 28,424, Dec. 27, 1904.

The liquid to be evaporated is fed into the tank 1 by the pipe 5, in the trough 6, and the upper layers only are

heated by the steam-pipes 20, provided with the wings 21, and round which the chains 23, are moved by the rollers 18, provided with flanges 22, and actuated from without the vessel. These chains serve to expose a large surface of the hot liquid, so that evaporation takes place easily. The lower portion of the liquid in the tank 1 is cooled by water which circulates through the pipes 26, 24, 25, and then passes by 27 to the perforated pipe 28. The water issuing from 28 falls on to the curved plates 29 and to the troughs 31, 32, and 33, and thence to the inner surfaces of the sides of the tank 7, which may be covered with metallic gauze, down which the water flows. This water serves to condense the vapour, and so maintain a partial vacuum within the apparatus. The water and condensed vapour collect in the trough 9 and flow away through the siphon 34. Any uncondensed vapour is removed through the pipes 11, 12, and 15 by the exhauster 13, 14 and by the ejector 16, 17, actuated by the vapour delivered by the exhauster 14. Any solids deposited during the evaporation are carried by the conveyor 28 to an outer trough from which they can be removed. Claim is made for the acceleration of the vapourisation by the partial condensation, caused by the water flowing down the sides, and for operating the ejector by the vapour from the exhauster.—W. H. C.

II.—FUEL, GAS & LIGHT.

Gas Plant for Methane-Hydrogen at Truro —. J. Gas Lighting, 1905, 90, 225—228.

THE plant which is capable of producing 200,000 cb. ft. of methane-hydrogen gas per 24 hours comprises an upright generator 6 ft. diam. by 20 ft. high, condenser-scrubbers, with exhausters, blowers, pumps, and engines in duplicate, station meter, relief holder, mixing meter and benzol carburettor. The generator is filled with coke and then blown up to incandescence, the waste-gas escaping part of the way up the generator to the stack pipe, so that the fuel above is dried and heated before it comes down into the hot zone, and also serves to filter out the finely divided carbon produced during the "run." When the requisite temperature has been attained, the valves are altered and steam and tar are injected into the body of incandescent fuel. The tar is decomposed into carbon and gaseous products, the steam combining with the coke and separated carbon to produce water-gas. A further quantity of steam, injected at the bottom of the generator serves to produce "straight" water-gas which passes away with the gas produced by the mixture of tar and steam. One gallon of tar and 28 lb. of coke will yield 1000 cb. ft. of gas of the following composition:—Hydrogen 58.7 per cent.; methane 10.0; unsaturated hydrocarbons 1.3; carbon monoxide 20.0; nitrogen, carbon dioxide; sulphuretted hydrogen, &c., 10.0 per cent. The gas has a calorific value of from 350 to 400 B.T.U. and is mixed with ordinary coal gas in the foul main, where it takes up a considerable quantity of illuminants from the hot tar. With coal-gas of 15 candle illuminating power, a mixture containing 20 per cent. of methane-hydrogen requires no further enrichment, whilst with 30 per cent. and 50 per cent., one-fifth and one-third gals. of 90 per cent. benzol will bring up the illuminating power of the mixture to 15 candles. The methane-hydrogen is said to take up the enriching benzol better, and to retain it in a gaseous form more perfectly, than ordinary water-gas. The cost per 1000 cubic ft. is given as:—Fuel (at 15s. per ton) 3.38 pence, labour 0.79 pence, tar (at 1d. per gal.) 0.27 pence, benzol (at 1s. per gal.) 3.48 pence, and boiler 1.0 pence, making a total of 8.92 pence.—W. H. C.

Oils for Safety Lamps; Notes on —. G. P. Lish. Trans. North Eng. Inst. Mining and Mech. Engin., 1905, 55, 136—138.

PATENT safety-lamp oils are mixtures of fatty oils varying proportions of the distillate from petrol which passes over just before the lubricating oil. The distillate is termed "mineral colza." It has a flashing point of 240 to 260° F. (Pensky-Martens' close test) a sp. gr. of 0.830. The flashing-points of patent safety-lamp oils range from 250° to 290° F., and are frequently about 270° F. In testing the burning qualities of different oils, 50 grms. of the respective samples were placed in the bottom safety-lamps and burnt in a photometer, wicks being regulated so as to give a constant light 0.4 candle power. After six hours, the residual oil was weighed, the difference between the weight and the original weight being the quantity of oil consumed. In determinations with a patent safety-lamp oil, 26.21-7 grms. of oil were consumed, the average being Colza oil burned very badly, and the petroleum consumed was 22.8 grms. Cottonseed oil had a tendency to lead to charring of the wick at the top; amount consumed was 22.3 grms. Seal and whale were no better, though niger-seed oil gave slightly satisfactory results. Speaking generally, no one oil showed any pronounced superiority in illuminating power, and price must therefore be the chief factor in selection. As regards the mineral oils, the American petroleum distillate already referred to, was found to be the best, showing a consumption of 18.7 grms., the light burnt steadily with a low wick, and for the time was above 0.4 candle-power. This experiment contradicts the assertions of certain dealers that it is a larger consumption of oil when the petroleum distillate is used alone. In the author's opinion, however, are many pits where a safety lamp oil with a flashing point of 270° F. might be safely replaced by "mineral colza" flashing at 250° to 252° F.; and when a flashing-point is essential it should be obtained by the addition of fatty oils. Experiments were also made with mixtures of cotton-seed oil and the petroleum distillate. A mixture of cotton-seed oil and petroleum distillate containing 75 per cent. of the latter was satisfactory. It flashed at 256° F., and showed a consumption of 19.1 grms. in the burning test. The backs of cotton-seed oil, viz., slight charring of the wick and separation of stearin in cold weather, can be avoided by the use of some rape-seed oil if the price per

Gas Generators; Impts. in Producer —. H. G. and C. H. Schill, Hyde, Cheshire. Eng. Pat. 11,104, May 21, 1904.

THE apparatus consists of the usual metal vertical vessel lined with refractory material, and is provided at the top with a feeding-hole, and at the bottom with a valve for the reception of combustible material. The top of the case is provided with a device for evaporating water by direct contact with heated surfaces, consisting of a number of iron bars placed chequer-work and below them a similar chequer-work of brick. An air-inlet fitted with a non-return valve communicates through the annular space formed between the metal case and the refractory lining, with the interior of the apparatus. To use the apparatus, a fire is lighted and the steam-raising device allowed to become hot, the products of combustion being drawn off through a chimney. The chimney draught is then cut off by means of a valve, and water admitted at a slight pressure on to the hot chequer-work. The steam thus generated is forced through the incandescent fuel, and the gas escapes out at the bottom of the apparatus through a non-return seal to a gas-holder. When the gas-holder is full the water supply is cut off and the chimney valve automatically opened; the draught thus created sucks in air, which becomes heated in passing down the annular space, and renews the combustion of the fuel, the products of combustion heating the steam-raising device. The chimney

is then again closed, and water admitted to generate steam.—L. F. G.

Apparatus for Subjecting Gases or Vapours to the action of Liquids or Liquid Agents or Vapours therefrom, especially applicable for Washing or Scrubbing or Enriching Illuminating or other —, and for Recovery Purposes. A. F. Browne and R. McKinlay, London. Eng. Pat. 16,427, July 25, 1904.

The apparatus consists of a casing of triangular section with a tank in its base to contain the "washing" or liquid. A travelling reticular open-work or chain-diaphragm is stretched over rollers inside in such a way as to follow the contours of the chamber, and to dip the liquid in the tank. The diaphragm is made to revolve by suitable means, and the gases to be purified are several times through it. A special form of elevatorless chain fitted with cups may also be mounted in the chamber, to continuously wet the revolving diaphragm by discharging over it liquid raised from the tank.—L. F. G.

[Heating]; Method of Treating [Drying] —. A. Mathys, London. From J. Gayley, New York. U.S. Pat. 25,213, Nov. 19, 1904.

The apparatus used for heating purposes are freed from moisture by passing them over pipes or surfaces cooled by a refrigerant.—L. F. G.

Purifiers; Impts. in —. J. Hodge, Lostwithiel, Cornwall. Eng. Pat. 8492, April 13, 1904.

The object of the invention is the purification of gas by a layer of oxide, without increasing the back pressure in the retorts. An upright purifier is fitted with a series of grids, each composed of a stationary and a movable part. It is charged through a suitable hopper and, when working, the grids cover the cross-section of the purifier. For the discharge of the purifying material, the sliding part of the grids is horizontally moved under the stationary part, by means of screws passing through screw-threaded stuffing boxes in the outer wall of the purifier; the purifying material falls through, and is discharged at the bottom by a trap-door. When working, the gas-ways are kept by upright pieces attached to the grids. Revolvers fixed to a central shaft and provided with vertical vanes, keep the purifying material in a loose state. With a cylindrical purifier, the grids are arranged in separate sections, while with a square one, two similar sections are used.—R. L.

Methods for Incandescent Lamps; Impts. in —. E. A. Arolan, London. From the General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 13,161, June 10, 1904.

Carbon, hydrocarbons, silica and other impurities are removed from filaments for incandescent lamps by the use of fluorine compounds, for example iodine pentafluoride. By treating the ordinary carbon filaments with this substance, the impurities are practically eliminated, while any remaining foreign matter is driven off during the exhaustion and heating of the filament.—R. L.

Lamps; Electric Arc Lamp —. The British Edison-Houston Co., London. From the General Electric Company, Schenectady, N.Y., U.S.A. Eng. Pat. 257, Jan. 5, 1905.

The electrodes are made by filling a thin metal tube with a powdered material in which are interspersed granules of refractory material. The powdered material may be cerium or titanium, and the granules chromite or graphite oxide.—L. F. G.

UNITED STATES PATENTS.

Artificial —; and Process of Making same. F. Meeker, Rye, N.Y. U.S. Pat. 787,458, April 18, 1905.

The fuel is divided and graded fuel such as bituminous coal or lignite is moulded into briquettes, with the addition

of a suitable binding material, such as rosin or the like. The block is then strongly compressed and heated, at first to a temperature high enough to dry the briquette, and subsequently to a higher temperature, sufficient to liquefy and diffuse the rosin or similar body through the briquette. A pigment may be added to the binding material, and claim is made for: "A compressed, strongly-adherent briquet, approximately anhydrous, and of approximate maximum density."—W. H. C.

Peat; Process for Treating [Drying] —. W. T. Griffin, Limoges, France. U.S. Pat. 788,100, April 25, 1905.

The claim is for a process according to which peat is excavated in thin layers and conveyed to a screening station, where the extraneous matter is separated, and the peat passed to a draining station. After draining off the water, the peat is conveyed to a compressing station, and is then alternately heated to 190–275 °F., to cause the cells to burst, and suddenly chilled to prevent volatilisation of the oils or hydrocarbons.—L. F. G.

Coking-Oven. J. M. Sullivan, Assignor to the American Coal Converting Company, Chicago. U.S. Pat. 786,694, April 4, 1905.

The apparatus consists of a number of beehive ovens arranged in parallel series, the party-walls separating adjoining ovens being provided with passages controlled by dampers. A flue extends between the series of ovens, and has passages, also controlled by dampers, communicating with the individual ovens of the series. Means are provided for forcing air through this flue, to promote the draught through the ovens. By suitably arranging the dampers, alternate ovens in each series can be made to communicate with the flue through the adjoining ovens.—W. C. H.

Gas-Producer. W. O. Amsler, Assignor to the Amsler Engineering Co., Pittsburg, Pa. U.S. Pat. 785,929, March 28, 1905.

The producer consists of a vertical combustion chamber, provided with a series of poke-holes in the clinkering zone, and arranged above a circular water-sealed trough. A cylindrical apron of the same internal diameter as the combustion chamber is attached to the bottom of it, and extends below the level of the water in the trough, and has a series of openings, of sufficient size to allow of the removal of clinkers, arranged between the bottom of the combustion chamber and the level of the water. A stand-pipe of large area, with closed sides, rests on the bottom of the trough, and extends upwards, concentrically with the producer, to a height intermediate between the bottom of the combustion chamber and the level of the seal. This stand-pipe is connected through the apron with a fluid-supply pipe immediately above the water-seal. A conical hood, composed of non-perforated plates, is arranged over the stand-pipe, with a passage for fluid between them, and a smaller hood is similarly arranged just above the apex of the larger hood with a passage for fluid between the hoods.—W. C. H.

Gas-Producer. F. W. Johnstone, Mexico. U.S. Pat. 785,955, March 28, 1905.

The producer consists of a vertical fire-chamber, from the top of which an open-bottomed retort hangs, and extends more than half-way down into the chamber. The gas-discharge pipe leads from the top of the chamber. Fuel is supplied to the retort through a covered feed-hopper, provided with a grate and a poker-bar which passes through the cover and the gate. Fuel which passes out of the bottom of the retort into the surrounding fire-chamber space between the walls of the producer and the retort, is raised into the fire-chamber space by means of lifting-rods (pokers) inserted into the chamber through openings in the wall, provided with seat-blocks and joint-blocks fitted and movable in them. The lifting bars can be inserted on two levels. Tuyeres pass through the lower portion of the wall of the fire-chamber, and are "recessed on their lower sides to form water-cups."—W. C. H.

Gas-Producer ; Suction — H. F. Smith, Lexington, Ohio. U.S. Pat. 786,063, March 28, 1905.

An arrangement for supplying steam and heated air to suction gas-producers, each proportioned to the load on the engine, and changing in time with the changes of the load. A weighted cylindrical vessel, mounted on knife-edges, is supplied with water to a constant level, and provided with an overflow, and with an outlet port controlled by a valve. The air-supply pipe is concentric with the water vessel, and contains an air-vane, connected with the vessel by a rod, also concentric with the vessel. As the air enters the pipe it moves the vane and tilts the water vessel so that a certain amount of water escapes through the valved outlet into the air-supply pipe. The air and water pass into a chamber, containing a number of discs, which are heated by arranging this vessel in the path of the exhaust from the engine, whereby the water is converted into steam and the air is heated.—W. C. H.

Gas ; Apparatus for Generating — G. W. Parker, New York, N.Y. U.S. Pat. 787,539, April 18, 1905.

A COLLAPSIBLE tube *dd*, made up of a number of segments and having perforations through which the gas may pass, is suspended from the support *s*, in the centre of an approximately vertical retort, which tapers slightly towards the top. The tube is centred by means of the appliance *h*, which is attached to the bottom cover of the retort.

—W. H. C.

Gas-Producer. J. Reuleaux, Wilkesburg, Pa. Assignor to A. Laughlin, Sewickley, Pa. U.S. Pat. 788,378, April 25, 1905.

A GAS-PRODUCER with a water-sealed bottom is provided at the top with a dome-shaped air distributor, and surrounded by an air-heating chamber. A series of lateral branches connect the air-heating chamber to the air-distributor, and an air-flue extends from the latter centrally into the fuel. Water-sealed valves are provided for admitting air, and for drawing off the gases.

—L. F. G.

Gas from Oils ; Apparatus for Making — N. G. Hock, Greeley, Col. U.S. Pat. 788,405, April 25, 1905.

The apparatus consists of a number of horizontal retorts mounted at different elevations, their ends connected together by detachable elbows in such a manner as to

secure a flow of liquid through the whole length of retorts. Inside the upper retort is placed a horizontal pipe extending through it and with the corresponding detachable elbow, to convey material into the apparatus.—L. F. G.

Gas-Purifier — A. Steinbart, Carlstadt, N.J. U.S. Pat. 787,593, April 18, 1905.

THE apparatus consists of two vessels connected at their upper ends. The gas is treated with a water-spray in the first vessel and then passes to the second vessel, in which are two horizontal partitions, united by a central vertical tube, this second vessel being open at the top and provided with a water supply at the bottom. In this vessel the gas passes through a series of tubes, each provided with a core, around which is arranged a helical web; the tubes are disposed in a circle around the central tube and also connect the horizontal partitions.—W. H. C.

FRENCH PATENTS.

Gas, Blast-furnace ; Process for Heating Coke-ovens and other Industrial Furnaces by means of — J. Hulin. Fr. Pat. 348,402, Feb. 8, 1904.

THE process consists in dividing the blast-furnace gas into two portions, and using the first portion to heat the second, which is the combustible to be used for heating coke-ovens, &c. This preliminary heating may be effected either directly or indirectly through the medium of the gas by the help of which the second portion is to be burned, or by combination of the two methods. The heat of the second portion is carried out in chambers constructed of refractory material.—W. C. H.

Gas and Air ; Process and Apparatus for Preparing Mixtures of — Selas Ges. m.b. H. First Added dated June 29, 1904, to Fr. Pat. 338,967, Aug. 19, 1904. SEE Eng. Pat. 16,288 of 1904 ; this J., 1904, 977.—T. B.

Gas, Illuminating ; Process and Apparatus for the Manufacture of — with continuous admission of Coal. Busse. Fr. Pat. 348,411, Dec. 1, 1904.

THE coal is introduced into the gasifying chamber in such a way as to be spread out in as thin a layer as possible on the inclined sides and on the bottom of the chamber. The gasifying chamber is wider at the top than the bottom, are horizontal with inclined walls, and on the top are arranged a series of hoppers and grooved cylinders, by which the coal is fed in a thin layer on to the inner face of the inclined walls, which are strongly heated externally. The coal is removed by a mechanical pusher, the end doors of the chamber being opened for the purpose.—W. C. H.

Gas for the Production of Motive Power ; Process and Apparatus for the Manufacture of — E. Fleischer. Fr. Pat. 348,748, Dec. 10, 1904.

[*Dyestuff*] *Anthracene Compound and Proc. of Making same*. R. H. Scholl and O. Bally, Mannheim. Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 787,859, April 18, 1905.

NEW anthracene compounds, called benzanthrones, are produced by condensing oxanthrol with glycerin in presence of sulphuric acid. On melting with alkali hydroxide these yield violet-blue dyestuffs which dye vegetable fibres substantively from a vat containing an alkali hydro-sulphite.—E. F.

FRENCH PATENTS.

Indoxyl [Indigo Dyestuffs] and Derivatives; Production of —. Badische Anilin und Soda Fabrik. Fr. Pat. 348,980, Feb. 29, 1904.

INDOXYL, or its derivatives, are obtained by melting hydroxyethylaniline $C_6H_5NHC_2H_4OH$, or certain of its derivatives, with alkali hydroxides, alkaline earth hydroxides, alkali metals or their amides, or any other compound capable of decomposing water. The melts are heated to a temperature of 250° — 290° C. The derivatives of hydroxyethylaniline which may also be used, are its alkali salts, homologues, carboxylic acids and derivatives alkylated in the amino-group, also dihydroxyethylaniline, $C_6H_5N(C_2H_4OH)_2$. For example, 137 kilos. of hydroxyethylaniline and 500 kilos. of potassium hydroxide are heated in an autoclave for one hour to 280° — 290° C. On dissolving in water and blowing air through the solution, indigo is deposited (see also U.S. Pat. 772,775 of 1904; this J., 1904, 1084). —E. F.

Dyestuff, Sulphide; Production of Yellow —. Actien-Ges. f. Anilin-Fabr. Fr. Pat. 348,900, Dec. 6, 1904.

1-THIOCYANO-2,4-DIAMINO BENZENE, obtained by the action of potassium thiocyanate on 1-chloro-2,4-dinitrobenzene is heated with sulphur from 200° to 240° C. The product dyes unmordanted cotton in greenish-yellow shades, very fast to fading.—E. F.

[*Anthracene Dyestuff*] *Product of the Anthracene Series; Production of a New* —. Farbenfabr. vorm. F. Bayer and Co. Fr. Pat. 348,926, Dec. 14, 1904.

ANTHRAQUINONE is transformed into 1-hydroxy-4-diazo-anthraquinone by treatment with nitrous acid in sulphuric acid solution in presence of mercury or mercury compounds, and with or without the presence of boric, arsenic or phosphoric acid, or of other compounds acting in a similar manner. This new product is converted into erythrohydroxyanthraquinone by treatment with alcohol or with other bodies acting on diazo compounds in the same manner, and into quinizarin by treating with concentrated sulphuric acid. For example, 10 kilos. of anthraquinone, 20 kilos. of sodium nitrite, 5 kilos. of crystallised boric acid, 2 kilos. of mercurous sulphate and 300 kilos. of sulphuric acid of 66° B. are heated from 120° to 150° C. until a sample is almost completely soluble in water. The melt is cooled, poured into 1000—1500 litres of ice-water, filtered from small quantities of insoluble matter, and the diazo solution so obtained, is heated with 500 litres of alcohol to from 60° — 70° C. Nitrogen is evolved, and erythrohydroxyanthraquinone separates in yellow needles.—E. F.

[*Anthracene Dyestuffs*] *Anthraquinone and its Derivatives; Process for the introduction of Hydroxyl Groups into* —. Farbenfabriken vorm. F. Bayer and Co. Fr. Pat. 348,927, Dec. 14, 1904.

THE introduction of the hydroxyl groups into anthraquinone derivatives by heating with concentrated or weakly fuming sulphuric acid, in presence or absence of boric, phosphoric or arsenic acid, etc., is found to take place much more easily in presence of even very small quantities of mercury or selenium, or of their compounds. For example, 10 kilos. of Alizarin Bordeaux (1,2,5-tetrahydroxyanthraquinone) are dissolved in 200 kilos. of sulphuric acid of 66° B. and heated to from 170° — 180° C.

with the addition of 0.5 kilo. of selenious oxide (SeO_2). In a short time 1,2,4,5,6,8-hexahydroxyanthraquinone is formed with intermediate formation of 1,2,4,5,8-pentahydroxyanthraquinone.—E. F.

GERMAN PATENTS.

Dyestuffs, Monoazo: Process for Preparing Blue —. Badische Anilin und Soda Fabrik. Ger. Pat. 158,499, Dec. 19, 1902.

Azo dyestuffs which give fast indigo blue to greenish blue shades on wool are obtained by combining the diazo derivative of 1,8-dinitro-4-naphthylamine with aliphyl derivatives of 1,8-naphthylaminesulphonic acid.—T. F. B.

ω -Sulphomethylantranilic Acid: Process for Preparing —. Badische Anilin und Soda Fabrik. Ger. Pat. 155,628, March 12, 1903.

ω -SULPHOMETHYLANTRANILIC ACID,

is produced by the action of sulphites or bisulphites on the product resulting from the condensation of equimolecular proportions of anthranilic acid and formaldehyde. For instance, a mixture of 137 parts of pure anthranilic acid and 80 parts of 40 per cent. formaldehyde solution is heated for a short time at 59–60° C., and the product is heated and stirred with a solution of 255 parts of sodium sulphite in 500 parts of water. The salts of the resulting acid are converted by metallic cyanides into ω -cyanomethylantranilic acid.—T. F. B.

Dyestuffs, Anthracene: Process for Preparing —. Badische Anilin und Soda Fabrik. Ger. Pat. 155,572, Aug. 11, 1903. Addition to Ger. Pat. 154,337, Feb. 22, 1903.

POLYHYDROXYANTHRAQUINONESULPHONIC acids are heated with sulphonic acids of aromatic amines in presence of dehydrating agents. Twenty kilos. of polyhydroxyanthraquinonesulphonic acid, 40 kilos. of sodium sulphamate and 10 kilos. of phosphoric anhydride are heated in an autoclave for one hour at from 200–205° C.; the product is poured into water, dissolved by heating, salted out, filtered and washed. The dyestuff dyes unmordanted wool bluish-red, chromed wool reddish-blue, and alumina-mordanted wool violet shades.—T. F. B.

Dyestuffs, Monoazo: Process for Preparing Yellowish-red —, specially suitable for Producing Lakes, from Anthranilic Acid Alkyl Esters. Badische Anilin und Soda Fabrik. Ger. Pat. 154,871, Oct. 4, 1903.

The yellowish-red dyestuffs obtained by combining diazotised anthranilic esters with β -naphthol are suitable for the preparation of colour lakes, which are very fast to washing and light.—T. F. B.

Dyestuffs, Monoazo: Process for Preparing —. Chem. Fabr. vorm. Weiler ter Meer. Ger. Pat. 155,083, Feb. 20, 1903.

THE sulphonic acids of 1,2-aminonaphthol cannot be successfully diazotised in presence of mineral acids; by diazotising with neutral nitrite solutions, impure dyestuffs result. The acids may, however, be diazotised in presence of excess of organic acids such as acetic acid or oxalic acid. The dyestuffs obtained by combining the diazo compounds with α - or β -naphthol, 1,5-aminophenol, &c., are of no technical value, but those obtained by combining with resorcinol in presence of excess of alkali hydroxide are of practical value; they dye wool red shades, converted to violet or violet-black on subsequent treatment with chromium salts, and to brown with iron salts. The 1- and 6-monosulphonic acids and the 4,6-disulphonic acid of 1,2-aminonaphthol may also be utilised for the production of such dyestuffs.—T. F. B.

Glycollic Acids of Pyrogallol and its Alkyl Ethers: Process for Preparing the —. Act.-Ges. f. Anilinfabr. Ger. Pat. 155,568, Feb. 27, 1903. XX., page 559.

Dyestuffs of the Cynanine Series: Process for the Preparation of Sensitising — [for Photographic Purposes]. Act.-Ges. f. Anilinfabr. Ger. Pat. 155,541, Jan. 1903. XX., page 563.

Dyestuffs containing Nitrogen: Process for Preparing New —. W. König. Ger. Pat. 155,782, June 3, 1903.

DYESTUFFS containing the pyridine nucleus are obtained by the action of a cyanogen halide on pyridine or on primary or secondary aromatic amine, or derivative thereof in presence or absence of a solvent. One mole of the cyanogen halide is used to 1 mol. of pyridine or 2 mols. of the amine. The dyestuffs obtained are stated to be practically pure, and to produce shades on wool silk which vary according to the amine used (e.g., orange red, violet).—T. F. B.

Dyestuffs, Diazo: Process for Preparing Primary — from 2,5,7-Aminonaphtholsulphonic Acid. K. O. Ger. Pat. 155,740, Aug. 18, 1903. Addition to Ger. Pat. 151,332, March 14, 1903.

DYESTUFFS which give "Bordeaux" to violet shades on wool, transformed to brownish-black and to violet on subsequent chroming, are obtained by combining diazotised amino-compound with 2,5,7-aminonaphtholsulphonic acid, and then combining this dyestuff with diazotised chloro-derivative of o -aminophenol. The following are mentioned as first components:—Sulphonic acid, chloro-metanilic acid, p -nitraniline- o -sulphonic acid, p -toluidine- m -sulphonic acid; and naphthionic acid. The following o -aminophenol derivatives may be used: p -chloro- o -aminophenol, o - p -dichloro- o -aminophenol, p -chloro- o -aminophenol- o -sulphonic acid.—T. F. B.

Anthrachrysonedialkyl Ethers [Anthracene Dyestuffs] Process for Preparing —. Farbwerke vorm. Meister, Lucius and Brüning. Ger. Pat. 155,633, Dec. 25, 1903. Addition to Ger. Pat. 139,424, March 22, 1902.

NEGATIVELY substituted Anthrachrysones (dinitro or tetrabromoanthrachrysones) are heated with dialkyl sulphates. The dialkyl esters thus produced are said to be of technical value, e.g., that from tetrabromoanthrachrysones gives blue dyestuffs when heated with aromatic amines.—T. F. B.

Dyestuffs, Monoazo: Process of Preparing Yellowish-red —. Farbwerke vorm. Meister, Lucius and Brüning. Ger. Pat. 158,148, Feb. 14, 1904.

THE diazo derivatives of o -aminosalicylic acid and its derivatives (e.g., nitro- or sulphonic acid derivatives) combined with derivatives of β -ketonealdehydes in which the aldehyde hydrogen atom has been replaced by an alkyl, aliphyl, alkyloxy or aliphylamino radical. These dyestuffs produce pure yellow shades, fast on wool on cotton mordanted with chromium or copper salts.—T. F. B.

V.—PREPARING, BLEACHING, DYING, PRINTING, AND FINISHING TEXTILE YARNS, AND FIBRES.

Silk Mordanting. G. H. Hurst. J. Soc. Dyers and Colourists, 1903, 21, 130–132.

THE decrease in lustre produced on treating silk with various mordants at elevated temperatures is found due to the surface of the fibre becoming covered with a number of excrescences, due to the precipitation of mordant oxide on the fibre. The appearance of these excrescences generally begins between 140° and 150° C., and then they appear on the surface of the fibre; at higher temperatures, the deposit of oxide appears to penetrate further into the fibre, the appearance of which then becomes quite "dead." Treatment with dilute mineral acid removes a portion of this deposit, but does not restore the lustre to the fibre. Little or no diminution of lustre was produced by ordinary mordants between temperatures of 70° and 120° C., but the mordanting under such conditions is a very

ation, and the process is considered no better than the ordinary one of working at the ordinary temperature. Only mordant found to be applicable at temperatures $\leq 150^{\circ}$ F. was chromium bisulphite; a treatment for 48 hours, at a temperature of 180° — 190° F., was found to mordant silk fully, and to produce only very slight decrease in lustre; this treatment is stated to be especially adapted to mordanting in the case of Alizarin dyestuffs.

—T. F. B.

Le Fibres; Relations between the Chemical Conditions and Dyeing Properties of —. W. Suida. *Monatsh. f. Chem.*, 1905, 26, 413—427.

Assuming that cellulose is an alcoholic anhydride, any chemical activity which it may possess, is to be due to the reactivity of the alcoholic hydroxyl groups. As these are numerous and are, moreover, situated in the molecule with oxygen atoms combined in a way different from that with hydrogen, they may conceivably have an acid character. The formation, apparently with the hydrolysis of the molecule, of labile alkali compounds analogous to saccharates, supports this view.

With a view of ascertaining their dyeing properties, as acyl and alkyl derivatives of cellulose were prepared. To this end, several lots of cotton yarn (containing 18 per cent. of ash), which had been freed from fatty matters, were heated with acetyl and benzoyl chlorides, dimethyl sulphate and caustic soda, and alcohol (c.c.) and sulphuric acid (1 c.c.). The products obtained from acetyl chloride and benzoyl chloride contained approximately one acyl radicle per molecule of cellulose ($\frac{1}{2}\text{H}_{10}\text{O}_5$), after being washed, were immersed, for 24 hours at the ordinary temperature, along with samples of the original cotton yarn and of gun-cotton (containing 12.1 per cent. of nitrogen), in dilute solutions of Genta and Crystal Violet (basic dyestuffs), Bordeaux (a direct cotton dyestuff) and Azo Fuchsin B (an acid dyestuff), respectively. The results showed that the acid dyestuffs were absorbed freely and to the extent by cellulose and by its acyl and alkyl derivatives, the acid dyestuff did not dye in any instance. It thus appears that the activity of the hydroxyl groups in cellulose is so slight that the dyeing properties of a nucleus are uninfluenced by the conversion of the hydroxyl groups into acyl and alkoxyl groups, i.e., by their substitution.

Cotton acts energetically as a catalysing agent. When treated at the ordinary temperature with benzoyl chloride and caustic soda, the benzoyl chloride almost entirely disappears on agitating the mixture. An alkaline mixture, without the cotton, remains for some time almost entirely unchanged. An action, probably of a similar nature, takes place when small quantities of cotton are immersed in succession in a dilute solution of silver nitrate, the cotton becoming dyed and the solution turning decolorised and giving, when tested with silver nitrate, a precipitate of silver chloride. In this case the oxidation or decomposition of the dyestuff-salt is probably the cotton, and may possibly take place within the vat. The decolorised solution was found to be a precipitate, but this, it is considered, may be due to the various matters present in the cotton employed in the experiment.

Small quantities of purified wool were treated with acetyl chloride, acetic anhydride, ethyl bromide, and benzoyl chloride, in the water-bath for an hour with a mixture of 1 (200 c.c.) and sulphuric acid (1 c.c.), respectively, the wool being washed successively with alcohol and the various lots were treated for a quarter of an hour at 90° C., with solutions of the basic and acid dyestuffs mentioned above, samples of the wool in its unchanged state being submitted to the same tests, for comparison. The acylated and acetylated samples were thus found to be slightly tinted, while the wool in its original state was strongly dyed, by the basic dyestuffs. On the other hand, the treated wool was coloured a deep crimson and untreated wool merely faintly stained by the acid dyestuffs. Both acid and basic dyestuffs dyed in deep shades of red of wool which had been boiled in dilute sulphuric acid (200) and then well washed. On heating the acylated wool on the water-bath with a solution

of ammonium carbonate, the original properties of the wool were restored. In view of this fact, it is considered unlikely that there is any formation of an anhydride by the acylating and acylating reagents employed. It is probable that these act primarily upon the carboxyl-group, and secondarily upon the amino-group, with the production in the latter case of a salt or analogous compound. A salt is doubtless formed by the action of aqueous sulphuric acid.

No change could be detected in the microscopic appearance of the fibre after treating it with the reagents mentioned.

Silk.—Considering the close resemblance in properties between wool and silk, it is remarkable that the dyeing properties of the latter fibre are unaffected by treating it with the acylating reagents which were applied to the wool. On heating silk, however, with alcoholic sulphuric acid, it becomes changed in the same manner as wool. It is then dyed strongly from a neutral bath by acid, and but faintly coloured by basic dyestuffs, while, in its natural condition, silk is dyed feebly by the first and strongly by the second of these, under comparable conditions.

Theory of Dyeing.—The results obtained would appear to show that, in the case of wool and silk, dyeing with non-mordant dyestuffs is a simple chemical action. — E. B.

Yarn and Slubbing; Machine for Dyeing —. S. S. Partridge, Kidderminster. Eng. Pat. 8570, April 14, 1904.

The yarn or slubbing is carried on a horizontal framework suspended from a beam placed above the dye-vat and extending the whole length of the latter. To the ends of this beam are fixed slides projecting downwards, and which can move vertically in guides placed outside the vat. Each of these slides has a small roller at its lower end, which rests on a cross lever, and these levers are moved up and down by a suitable mechanism, thus causing the framework to move up and down in the dye-vat. The whole moving frame is partly counterpoised by weights. To each end of the horizontal yarn-frame is fixed a large ratchet wheel which gears with a ratchet on the side of the vat. As the frame rises and falls, these come into gear and so cause the frame to revolve on its axle a certain distance, which can be regulated by adjusting the ratchets. The poles which support the yarn are revolved individually by gear wheels or other suitable mechanism, and the whole framework can be lifted bodily out of the vat by means of an overhead pulley.—A. B. S.

Alizarin-Red; Dyeing Cotton in the Form of Cops, Spools &c. in —. J. Dolder, Esslingen, Switzerland. Eng. Pat. 13,484, June 14, 1904.

COTTON yarns (100 kilos.) in the form of cops and cross spools, after being mordanted with oil and alumina, are dyed in red from a bath containing alizarin (12.75 kilos. of the 20 per cent. paste), dissolved by means of strontium saccharate, $\text{C}_{12}\text{H}_{20}(\text{SrOH})_2\text{O}_{11}$ (1.075 kilos.). The yarns, it is stated, are very uniformly dyed, and the colour obtained is, in fastness and brilliancy of shade, equal to the dye produced in other ways.—E. B.

Tissue Printing; Process of —. C. Walker. Fr. Pat. 348,436, Feb. 9, 1904.

DESIGNS are printed upon one side of a tissue in such a manner as to penetrate more or less through the tissue. They are then attenuated on, or altogether effaced from, the side of the tissue to which they have been applied, being left on the other side, which is, or now becomes, the face of the tissue, with a softness and delicacy of appearance greater, it is stated, than it is possible to produce by direct printing.—E. B.

Tissue Printing; Process of —. C. Walker. Fr. Pat. 348,437, Feb. 9, 1904.

IN printing designs upon tissues by means of two or more rollers, the colour printed by each roller, except the last of the set, is pressed into the tissue by the rollers which subsequently operate, with the result that the colour applied by the last roller of a set appears, as a rule, less distinctly at the back of the tissue than the colours printed by the other rollers, the difference being especially noticeable in the case of raised tissues. To obviate this and, at the same time, to produce novel effects, a colour is printed on the back of the tissue by a roller upon which the whole of the design is engraved, the parts corresponding with those printed by the last roller of the set being engraved upon it in the ordinary manner, and the other parts being engraved in parallel lines, nearer to or further away from one another according to the degree to which the colour applied to the back of the tissue requires to be pressed, to meet the colours printed upon the face in the corresponding parts of the design.—E. B.

Tissues (Pile Fabrics); Process for Decorating —. F. Prud'homme and J. Chardonnal. Fr. Pat. 348,616, Feb. 9, 1904.

BRUSHES, mounted so as to rotate upon vertical axes and to move vertically and horizontally, are supplied with colour-mixtures or with sizing or other materials, which they apply to tissues passed, at full width underneath and in contact with them, either in a continuous manner or intermittently. The tissues are, in the latter case, drawn forward while the brushes are raised, and are held

stationary when the brushes are lowered and put in operation. Stencils may be interposed between the tissues and the brushes to vary the effects produced.—E. B.

GERMAN PATENT.

Dye-stuffs, Also: Process for the Production of Insoluble Red-brown — on the Fibre. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 155,349, Dec. 5, 1903.

VERY fast reddish-brown shades are produced by impregnating fabrics with β -naphthol, and then immersing them in a bath of diazotised *p*-nitrobenzene-*o*-toluidine. The diazotisation may be carried out at a temperature of 15°–20° C. By substituting α -naphthol or a mixture of the two naphthols for β -naphthol, deep puce shades are produced.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS

Potassium Chlorate and Hydrochloric Acid, Acceleration of the Reaction between — by Platinum. H. Z. Elektrochem., 1905, 11, 261–263.

THE reaction between chlorates and hydrochloric acid takes place in two stages; the first is the slow reverse reaction $\text{ClO}_3' + 2\text{H}^+ + 2\text{Cl}' = \text{ClO}' + 2\text{HClO}$, and in the second the hypochlorous acid thus formed immediately reacts with hydrochloric acid to form chlorine and water. The author enclosed normal solutions of thrice recrystallised potassium chlorate with twice the volume of *N*-hydrochloric acid in sealed tubes, which were heated in benzene for three hours to from 60°–70° C. The chlorate 2 c.c. of the liquid was then titrated with sodium sulphate, and the gaseous chlorine formed was calculated by measuring the volume of the liquid and the air above it. Experiments were made side by side with and without added platinum. The addition of piece after piece of platinum foil was found to increase the yield of chlorine by one-sixth, that of platinum black by two-fifths. By using a platinised platinum wire and keeping the reaction mixture agitated, the yield was doubled, whilst with platinum black, under agitation, a nearly six-fold increase was obtained. The author points out that the inverse reaction $\text{ClO}' + 2\text{HClO} = 2\text{H}^+ + 2\text{Cl}' + \text{ClO}_3'$ should be similarly favoured in presence of platinum, which is of significance in regard to the electrolytic production of chlorates.—W. A.

Potassium Ferricyanide; Action of Ammonium Chloride on —. J. Matschek. Chem.-Zeit., 1905, 29, 439–440.

POTASSIUM-AMMONIUM ferricyanide which is used for aniline black printing was made by Schaller (Bull. Chim., 1864, 1, 275) by boiling a solution of potassium ferricyanide with ammonium sulphate. The author substituted ammonium chloride for the sulphate with similar results, and obtained the best yield by dissolving 10 grms. of potassium ferricyanide in 20 grms. of water on the water-bath, adding 4.86 grms. of ammonium chloride and crystallising the solution. By boiling the solution for 12 hours, a Prussian blue containing ammonia is formed. The author explains this by the dissociation of ammonium chloride in aqueous solution: the acid thus set free reacts on the ferricyanide with formation of Prussian blue, and the latter is partially decomposed by the free ammonia with production of ferric hydroxide, and Prussian blue containing ammonia.—R. L.

Polysulphides; Study of the —. F. W. Küster and E. Heberlein. Z. anorg. Chem., 1905, 43, 53–84, 1905, 431–451.

FOR the experiments described, a solution of sodium sulphide was prepared by passing hydrogen sulphide into a solution of pure sodium hydroxide. On adding excess of sulphur to the sodium sulphide solution, the sulphur is dissolved rapidly at first, but complete saturation is attained only after a long time, especially with the dilute solutions. In this respect, the preparation of a solution of sodium polysulphide resembles that of a sol-

line in potassium iodide. Between 0 and 50° C. the solubility of sulphur in sodium sulphide solution is almost independent of the temperature, showing a very slight increase as the temperature rises. The amount of sulphur dissolved varies with the concentration of the sodium sulphide solution: it is greatest with a N/16 solution, the amount of which the amount of sulphur in the saturated solution corresponds to the formula $\text{Na}_2\text{S}_{5.21}$. It is probable that the solutions do not contain definite individual compounds, but consist of a mixture of different polysulphides in a condition of equilibrium, of which the tetrasulphide Na_2S_4 is characterised by relatively great stability, and polysulphides are hydrolysed considerably in aqueous solution, the degree of hydrolysis diminishing only as the sulphur content increases. The authors find that the polysulphides are salts of complex acids of the type $\text{H}_2\text{S}_x\text{S}_y$, which have a structure similar to those of the complex iodo-hydriodic acids, HI_3 and HI_4 . Experiments in which the potentials of platinum and electrodes in sodium sulphide solutions containing large amounts of dissolved sulphur were measured, showed that such measurements afford an index of the degree of saturation of the solution. The results obtained confirm the conclusion drawn from the chemical experiments, that up to the formation of the tetrasulphide, Na_2S_4 , the sulphur is firmly bound than that portion taken up subsequently.—A. S.

Calcium Carbide; Existence of a —. J. T. Nance. Chem. Soc. Proc., 1905, 21, 124.

The residue left after burning magnesium in carbon, or after heating magnesium with carbon or in air, giving carbon dioxide, be treated with water or dilute hydrochloric acid, a smell resembling that of geraniums is observed, owing to the presence of a hydrocarbon, produced by the action of water on the residue. The author states that the gas produced by treating the residue left gently igniting a mixture of magnesium powder and powdered wood charcoal with dilute hydrochloric acid consisted mainly of hydrogen, but it also answered to various reactions of acetylene. He concludes that a calcium carbide is formed which does not interact with water so vigorously as calcium carbide.—A. S.

Manganous Chromates. M. Gröger. Z. anorg. Chem., 1905, 44, 453–468.

The author determined the composition of the precipitates obtained by treating a solution of manganous chloride with potassium, sodium, and ammonium chromates under various conditions. The results obtained indicate that in cases soluble manganous chromate MnCrO_4 is first formed, from which ultimately insoluble chromic manganite $\text{Cr}_2\text{O}_3 \cdot 3\text{MnO}_2$ is formed, with separation of free acid. The extent of the transformation into the insoluble product increases with the time, the concentration of the solutions, and the temperature. Potassium manganate, when used in large excess and in highly concentrated solution, completely prevents the separation of chromic manganite, owing to the formation of the soluble double salt $\text{K}_2\text{Mn}(\text{CrO}_4)_2 \cdot 2\text{H}_2\text{O}$. Under other conditions, the separation of the chromic manganite is prevented partially by ammonium chromate, but not by sodium chromate.—A. S.

Ammonia; Formation of — from its Elements. Haber and G. van Oordt. Z. anorg. Chem., 1903, 4, 341–378.

From the results of the experiments described in a former paper (this J., 1905, 131), the authors calculated the free energy of formation of ammonia, and deduced the following values for the amounts of ammonia contained in mixtures of hydrogen, hydrogen, and ammonia in equilibrium at various pressures, and at the temperatures given:— at 98.51° C., 327° C., 8.72; 627° C., 0.21; 927° C., 0.02; and 1020° C., 0.012 per cent. The figures show that the synthesis of ammonia, in order to obtain a value of technical value, a catalyst is needed which will act satisfactorily at a temperature much above 300° C. Experiments with metallic

calcium showed that the reversible reaction $3\text{Ca} + \text{N}_2 + 3\text{H}_2 \rightleftharpoons 3\text{CaH}_2 + \text{N}_2$ occurs readily at a red heat, and is associated with the reaction $\text{N}_2 + 3\text{H}_2 \rightleftharpoons 2\text{NH}_3$. Ammonia was formed in sufficient quantity to be detected by the action of hydrogen on calcium nitride, but not by the action of nitrogen on calcium hydride. The limits of temperature within which calcium nitride and hydride can be used as intermediate products in the synthesis of ammonia are, however, so high, that the production of considerable quantities of ammonia in this way is impossible. By alternately acting on manganese with nitrogen and hydrogen, manganese nitride can be formed and again reduced to metal. The dissociation of the manganese nitride is associated with the formation of ammonia from its elements. The limits of temperature within which manganese can be used as a catalyst, whilst lower than with calcium nitride, are, however, too high to allow of results of technical value being obtained.—A. S.

Carbon Monoxide; Action of — on Ammonia. H. Jackson and D. Northall-Laurie. Chem. Soc. Trans., 1905, 87, 433–434.

If a mixture of dry carbon monoxide and ammonia be heated in presence of platinum, subjected to the silent electric discharge or to electric sparking, or treated with a high frequency current, a reaction occurs, ammonium cyanate being formed according to the equation:— $\text{CO} + 2\text{NH}_3 = \text{OCN} \cdot \text{NH}_4 + \text{H}_2$. As the temperature rises, the ammonium cyanate is rapidly converted into carbamide. The best results were obtained by using a spiral of platinum wire sealed inside a glass bulb, and heated by the electric current. Contrary to the view generally held, which is based on Kuhlmann's results (Annalen, 1811, 38, 62), the amount of ammonium cyanide formed is small. Among the other products of the reaction detected were ammonium carbonate (formed by the action of water on the carbamide), methane and nitrogen. It was observed that the best yields of ammonium cyanate and carbamide are obtained with a heated spiral of platinum wire, heated platinised asbestos, and the ordinary spark from an induction coil, whilst the silent electric discharge and high frequency current favoured the production of complicated cyanogen compounds.—A. FRENCH PATENTS.

Sulphuric Acid: Process and Arrangement for Leading to the Lead Chambers for the Manufacture of —, the Water required for the Reaction. Soc. Anon. Ing. L. Vogel per la Fabbricazione dei Concimi Chimici. Fr. Pat. 348,769, Dec. 10, 1904.

THE usual arrangement of lead chambers with a Glover and a Gay Lussac tower is supplemented by another tower, into which a portion of the gases from the pyrites kiln is diverted, and in which the gases are exposed to a shower of water or of dilute sulphuric acid, the water vapour so produced being conveyed, with the accompanying gases, to the top of the lead chambers by a pipe from which vertical branches lead them downwards into the body of the chambers, thus making the direct injection of water or of steam from an independent boiler unnecessary.—E. S.

Nitrates, Nitrites, Sulphonitrates or Sulphonitrites of Calcium, Sodium, or Potassium; Process of Making —. J. Price. Fr. Pat. 318,670, Nov. 14, 1904.

SEE Eng. Pat. 21,297 of 1903; this J., 1905, 276.—T. F. B.

Pyrites: Apparatus for Treating —. W. B. Simo. Fr. Pat. 348,866, Nov. 22, 1904.

SEE U.S. Pat. 778,149 of 1904; this J., 1905, 90.—T. F. B.

Soap: New Process of Preparing Soda [Sodium Bicarbonate] intended for the Manufacture of —. C. Ferr. Fr. Pat. 348,708, 1904. XII., page 552.

VIII.—GLASS, POTTERY, AND ENAMELS

Glass: Hardness of —. A. Leerenier. Bull. S. Chim. de Belg., 1905, 19, 16—28.

THE Herz-Auerbach method of expressing the absolute hardness of bodies as a function of the elastic limit whose sphere of the substance is pressed against a plane surface of the same material has given, in the case of glass, abnormal results which do not correspond with relative hardness as understood industrially. The author has devised a process for the determination of the hardness of glass based upon the relative resistance which the glass presents to the cutter's wheel. He employs a machine provided with a wheel of red sandstone which cuts facets in the glass under a constant pressure, and he notes the time required to cut away an equal volume of substance from different glasses of the same shape and size. The results obtained were totally at variance with the theoretical hardness calculated from the composition of glass by means of Auerbach's coefficients, but they were in more or less direct concordance with the coefficient of resistance of the various glasses to tensile and compressive strains. The cutting action of the wheel can, in fact, be regarded as a combination of compressive and tensile forces.

As regards the influence of the composition of the glass upon the hardness as thus determined, the author concludes:—In a general manner, the soda glasses are harder than the potash glasses containing equal proportions of silica (by volume). With the purely lime-soda glasses the hardness for the same proportion of silica increases with increase of the lime and decrease of the soda. Boric acid imparts great hardness to the glass. With the glasses the introduction of soda or lime considerably increases the hardness.—J. F. B.

Colours: Brown Pigments for Underglaze —. Sprechsaal, 1905, 38, 557—559.

OWING to the high temperature and reducing atmosphere of the hard-porcelain kiln, it is difficult to obtain deep gradations of brown on the ware; but greater success is possible with stoneware or soft porcelain fired at a temperature 10 in an oxidising atmosphere. As brown pigments the oxides of iron, chromium, aluminium and zinc are suitable, those of cobalt, manganese, nickel and antimony being also useful for certain purposes. However, to reduce their fusibility, it is necessary to use them in a form in which a trivalent oxide is combined with a divalent one, after the manner of spinel. Thus, a blackish-brown is obtained with 76.5 parts of chromic oxide and 23.5 of ferric oxide, the mixture being fired at a high temperature and in a reducing atmosphere. A perfect black is obtained on replacing one-half the ferric oxide by cobalt oxide, and firing under the same conditions. The addition to the first mixture, of 51 parts of alumina gives a reddish-brown, whilst doubling the ferric oxide and alumina in the latter recipe furnishes a more reddish tone. In both cases an oxidising fire, at the temperature of cone 10, is necessary. For lighter shades, alumina is unsuitable to replace chromic oxide, owing to its inferior capacity for combining with iron, the result being that the glaze attacks and fuses the pigment. On the other hand, chromic oxide can be almost completely deprived of its colouring power by zinc oxide, whilst leaving the faculty of resisting the glaze unimpaired. In this way, a light red-brown can be obtained from 38.3 parts of chromic oxide, 40 of ferric oxide and 40.5 of zinc oxide. A brighter shade is furnished by chromic oxide 23 parts, ferric oxide 32, alumina 3 and zinc oxide 40.5 parts. The pigment for yellowish-brown consists of chromic oxide 15.3 parts, ferric oxide 32, alumina 20.4 and zinc oxide 40.5 parts; whilst

yellow-brown is obtained with chromic oxide 15.3 parts, oxide 20, alumina 28 and zinc oxide 40.5 parts, various dark brown shades, manganese oxide is useful in combination with chromic oxide, e.g., 76.5 parts of the oxide to 114.5 of the former, the mixture being heated to a high temperature. The same oxide may also be used in place of part of the ferric oxide in the black pigment mentioned, the mixture being fired in the porcelain kiln. Still darker brown shades are furnished by the addition of nickel oxide to the pigment mass: thus, 23 of chromic oxide, 32 of ferric oxide, 15.3 of alumina, 10 of zinc oxide and 10 of nickel oxide give a deep brown, fired at cone 10 in an oxidising atmosphere.

The foregoing mixtures are ground along with 10 per cent. of sherds, when intended for use on porcelain, with 15 per cent. of sherds and 10 per cent. of glaze for stoneware. A light yellow-brown may be produced by the aid of antimony oxide; but, owing to the tendency to liberate gas in the kiln, and thereby produce cracks in the glaze, the mixture, when prepared, must be fired with 33 per cent. of sherds and heated at the rate of cone 10 in an oxidising atmosphere. The result for a paler yellow-brown than that already given is compounded of: Chromic oxide 15.3 parts, ferric oxide 20, alumina 25.5, antimony oxide 7.2 and zinc oxide 40.5 parts.—C. S.

Slip Body: Measuring Viscosity of —. Simonis. *Sprechsaal*, 1905, 38, 597–601.

The viscosity of slip body does not form a measure of the plasticity of the constituent clay, as in the one property is accompanied by an augmentation of the other; and the measurement of the viscosity is of importance in connection with the influence of added alkalis, such as alkalis. The apparatus used for the determination consists of a graduated cylinder, 100 mm. high and 30 mm. internal diameter, with a nozzle 2 mm. in diameter. A narrow glass tube open at both ends, passes down through the upper house stopper of the cylinder, and is attached to an alcohol pointer, indicating on the scale the level of the end of the tube in the cylinder. The principle is that of the Mariotte bottle. The coefficient of fluidity is determined by dividing the volume escaping from the nozzle at a given time by the pressure recorded on the scale. In testing the influence of caustic soda on slip body, a mixture composed of 40 grms. of fine Zettlitz kaolin and 100 of water was used. The action of the alkali increases at first, and then rapidly attains a maximum with 10 grms. of sodium hydrate. Caustic potash is less effective, and though the same maximum is reached, a concentrated solution of the alkali is necessary to obtain this result. By means of similar determinations it is possible to avoid adding to slip body for casting, excessive amount of saline matter that is likely to prove objectionable in later stages.—C. S.

X.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

ENGLISH PATENT.

Treating —, for Preserving and like purposes. E. Weed, Fayetteville, N.C., U.S.A. Eng. Pat. 29, Dec. 29, 1904.

Wood is subjected to the action "of a relatively non-volatile substance having a higher boiling point than some of the natural constituents of the wood," and is then, while subjected to the action of a solvent of the constituents removed, and is lastly again treated with a hot liquid having a higher boiling point than the solvent used. The wood thus prepared is ready for treatment with a preservative fluid. The first bath may be of melted rosin, heated to 320° F., the solvent used may be gasoline; and the rosin may again be used, heated sufficiently to the boiling point of the gasoline from the pores of the wood. (Compare Eng. Pat. 4353, 1903; this J., 1903, 692.)—E. S.

UNITED STATES PATENTS.

Fire-Bricks, Crucibles, Retorts or other Refractory Articles: Process of Manufacturing —. P. B. Smith, Russia. U.S. Pat. 787,770, April 18, 1905.

A MIXTURE of powdered chromic ore from which easily fusible impurities have been removed, the clay, and pure aluminium hydroxide, with or without carbonaceous material, is moulded, pressed and burned.—A. S.

Refractory Material: Method of Manufacturing —. G. C. Glynn, Iola, Kans., Assignor to F. B. Smith. U.S. Pat. 788,131, April 25, 1905.

KAOLINITE is freed from moisture or uncombined water, pulverised, and then burnt in the presence of "free air" to eliminate organic and volatile impurities, and "to reduce the ferric compound to metallic iron." The heated mass, with or without the addition of a flux, is plunged into cold water; the disintegrated mass obtained is allowed to cool, moulded under high pressure, dried and burnt at a high temperature.—A. G. L.

Refractory Material and Method of Making same. G. C. Glynn, Iola, Kans., Assignor to F. B. Smith. U.S. Pat. 788,132, April 25, 1905.

THE refractory material consists of a mixture of one part of finely-divided aluminium, three parts of ferric oxide, and four parts of titanite iron ore containing about 60 per cent. of titanite oxide, together with a binding agent, such as a solution of ammonium chloride of acid reaction.—A. G. L.

Cement-Kiln. C. Ellis, Assignor to Eldred Process Co., both of New York, N.Y. U.S. Pat. 788,503, April 25, 1905.

A PAIR of long rotatory kilns are inclined so that the material in one kiln travels in a direction opposite to that of the flow of material in the other kiln. At the stack end of each kiln there is a heat regenerator, continuous or otherwise, and means are provided for passing air through this regenerator, as well as means for conveying the air pre-heated by its passage through the regenerator of one kiln into the juxtaposed fuel-feeding end of the other kiln.—A. G. L.

FRENCH PATENT.

Cement; Artificial —. E. L. Candlot. First Addition, dated Dec. 3, 1904, to Fr. Pat. 334,705 of Aug. 19, 1903 (this J., 1904, 116).

IN the cement described in the main patent, a certain proportion of the clay introduced may be replaced by ferric oxide. In one of the examples given, 5 parts each of ferric oxide and gypsum are added to a mixture of 20 parts of clay with 100 parts of chalk, and the burning of such a composition is stated to be effected with less consumption of fuel than when no iron oxide is added.—E. S.

GERMAN PATENT.

Wood; Process for Removing Juices and Air from, and for the Simultaneous Colouring of —. P. Hampel. Ger. Pat. 158,103, Oct. 11, 1902.

THE wood is immersed in a bath of a fused metal or alloy having a relatively low melting point, such as tin, lead, antimony, bismuth, or alloys of these metals, in order to prepare it for subsequent treatment with a suitable impregnating liquid. It is stated that the juices and air contained in the wood are rapidly expelled, without burning or carbonisation taking place. During the treatment, the wood becomes dark-coloured. For the subsequent impregnation process, the use of linseed oil, cottonseed oil, or other fats or oils is recommended; the treated wood can then be employed as a substitute for vulcanite and other insulating materials.—A. S.

X.—METALLURGY.

Steel, Mild; Use of Cold-blown Pig-Iron in the Manufacture of —. Geilenkirchen. Stahl u. Eisen, 1905, 25, 328—334; 407—410; 463—469.

THE subject is treated under the following headings:—
(1) Cold-blown pig-iron in the process of refining by a blast of air; (a) hot blast in the converter process, (b) superheating of the pig-iron in the converter process, (c) economy of heat by reducing the proportion of nitrogen in the air-blast; (2) cold-blown pig-iron in the hearth-

smelting process: (a) preliminary heating of the flux (b) the Bertrand-Thiel process, (c) the continuous hearth smelting process, (d) the preliminary refining process (e) combinations of converter and Martin furnaces.—A

Alloys of Gold and Lead. R. Vogel. Z. anorg. Chem. 1945, 11—23.

AN extended study by thermal and microscopic methods of alloys ranging by 5 per cent. differences from pure lead to pure gold. The results of the freezing-point determinations are all shown in the diagram. The compounds are indicated, Au_2Pb , which separates

presented in the region B'Ce of the diagram, and which separates as represented in C'Dd. The alloy undergoes at 211° C., a molecular change during the evolution of heat; the two forms are referred to in the diagram by the letters α and β . Eutectic solidification occurs at 426°, 255°, and 215° C.; the solidification at 215° C. of the last eutectic is easily connected with the molecular change just mentioned, but the two are entirely distinct phenomena. The compound AuPb_2 forms large white rhombic crystals; it is exceedingly hard and brittle, and can be easily pulverised in a mortar. The compound AuPb_3 forms fine silver-needles, harder than lead and somewhat brittle, but less so than Au_2Pb . Micrographic examination of various alloys confirms the results of the thermal analysis.—J. T. D.

Metallurgy of —. C. Goldschmidt. Chem.-Zeit., 1905, 29, 424.

The separation of metallic silver from silver sulphate is effected by roasting silver sulphide, the author recommends the use of sheet cobalt in place of copper and iron. Silver is separated partly in the amorphous and partly in the crystalline condition; and better yields are stated to be obtained.—A. S.

ium; Method of Determining — and its application to Metallurgical Products. E. Campagne. II., page 561.

UNITED STATES PATENTS.

Cast Iron, and Steel; Process of Treating [Case-Hardening]. J. Lecarme, Paris. U.S. Pat. 792,626, April 25, 1905.

Addition of Oct. 10, 1902, to Fr. Pat. 327,984 of this J., 1903, 1052.—T. F. B.

Process of Roasting. S. B. Patterson.-Phillipsburg, N.J. U.S. Pat. 787,540, April 18, 1905.

The ore is continuously roasted within a receptacle, and the ore is intermittently fed in at the top. The subjected throughout its length to the action of steam, whilst at intervals steam at a lower temperature is injected into the lower layers of the ore. The roasted ore is intermittently withdrawn from the base of the body of ore.—E. S.

Concentration. A. E. Cattermole, H. L. Sulman, and H. F. Kirkpatrick-Picard, London. U.S. Pat. 787,474, April 25, 1905.

Eng. Pat. 17,109 of 1903; this J., 1904, 902.—T.F.B.

Apparatus for the Treatment of —. R. O. Reilly, Albuquerque, New Mexico. Assignor to T. J. Curran, Albuquerque. U.S. Pat. 788,330, April 25, 1905.

A water-jacketed smelting chamber is provided with air-chambers, sliding agitators, and a rotary distributor.—J. H. C.

Filtering Cell for Separating Slimes in Ore Treatment. G. A. Duncan, Deadwood, S.D. U.S. Pat. 787,739, April 18, 1905.

The filtering cell consists of a bag in which is disposed a frame, shorter than the bag, for keeping it extended. The frame consists of vertical spring-bars at relatively short intervals, and top and bottom side-bars. Around the exterior of the bag are arranged vertical check-bars in pairs, the two bars of each pair being locked opposite each other on opposite sides of the bag. The corresponding ends of the two bars of each pair are received in lotted plates by means of which they are pressed against the upper and lower side-bars of the inner frame. The portion of the bag which extends above the frame is rolled around a rod. In the bottom bar of the frame, are nipples which extend through water-tight joints into the filtering bag, and are connected, below the cell, to an exhaust pipe and a supply pipe. Means are provided for exhausting the air from the interior of the cell.—A. S.

Slimes; Process of Treating — in Ore Production. G. A. Duncan, Deadwood, S.D. U.S. Pat. 787,878, April 18, 1905.

A FILTERING-CELL (see preceding abstract) is immersed in the slime-bearing liquor contained in a tank, and the air is exhausted from the interior of the cell, whereby the liquid is sucked through, and the slime accumulated on the outer surface of the filtering-bag. The accumulated slime is then successively treated with a solution capable of dissolving the metal or metals which it is desired to recover, and with a washing liquid, these liquids being introduced into the tank, and sucked through the slime into the filtering-cell. The residual slime is finally removed by forcing water into the interior of and out through the filtering-cell, and directing jets of water against the outer surface of the bag.—A. S.

Furnace; Roasting —. F. J. Falding, New York. U.S. Pat. 788,098, April 25, 1905.

The ore is carried through a series of superimposed hearths, having concentric openings, by means of a rotating central shaft and detachable stirring arms, which are hollow and cooled by a circulating fluid.—J. H. C.

Copper; Precipitating Process for —. G. H. Waterbury, Denver, Colo., Assignor to the Waterbury Metals Extraction Co., Spokane, Wash. U.S. Pat. 788,443, April 25, 1905.

The solution is placed in a tank containing pieces of aluminium of suitable shape, and agitated therein by means of air and steam.—J. H. C.

FRENCH PATENTS.

Minerals; Process and Apparatus for Treating — with Fatty and Resinous Hydrocarbons and Sulphur. Schwartz Ore Treating Co., Fr. Pat. 348,958, Nov. 12, 1904.

The powdered minerals—wet or dry—are mixed with the hydrocarbons, sulphur or sulphides, and strongly heated. Steam or gas and finally fine jets of water are forced through the mass whereby the sterile gangue is separated from the metallic particles which remain partly with the hydrocarbon and partly with the sulphur. A jacketed cylinder capable of being heated, and provided with tuyères and a movable bottom is employed for this process.—J. H. C.

Zinc Ores; Treatment of —. E. Demenge, Fr. Pat. 348,733, Dec. 9, 1904.

The ores are smelted in a water-jacketed cupola furnace, using a strong blast. The volatilised lead and the precious metals are recovered in the metallic state. Zinc is volatilised and drawn off by a fan through a series of cooling and condensing chambers where it is deposited as oxide.—J. H. C.

Furnaces; Construction of —, for Roasting, & Mining, and similar purposes. U. Wedge. Fr. Pat. 348,793. Dec. 12, 1904.

SEE U.S. Pat. 777,577 of 1904; this J., 1905, 93. T. F. B.

Metals; Extraction of — from their Ores. J. Nicholas. Fr. Pat. 348,804, Dec. 13, 1904.

Zinc and cadmium are separated from the other metals by chlorination in a furnace, with subsequent lixivation, and separated from each other by known methods. If the residues contain lead and the precious metals, they are smelted by fluxed and reduced in a furnace; after re-smelting, aluminium is added, which on cooling forms a crust containing the precious metals. From the residues after pulverisation, other metals may be extracted by the action of nascent chlorine prepared in the ordinary way. Sulphur and sodium sulphate are recovered by known methods when present in sufficient quantities.—J. H. C.

Soldering Metals, particularly Aluminium, Copper and its Alloys, Iron and Steel, Nickel and German Silver; Alloy for —. A. G. Le Chatelier. Fr. Pat. 348,925, Dec. 14, 1904.

The best results are obtained with an alloy of zinc and cadmium containing about 20 per cent. of zinc, but as little as 15 per cent. or as much as 30 per cent. of zinc will be found suitable in some cases. Occasionally a little lead is added. The alloys are prepared by adding the zinc to the cadmium while fused in a crucible.

—J. H. C.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Ammonia; Electrolytic Oxidation of —. E. Müller and E. Spitzer. Ber., 1905, 38, 1188–1190. (See this J., 1905, 279 and 280.)

The authors have shown that the conversion of NO_2 ions to NO_3 ions at the anode, when iron anodes are used, depends only on the concentration of hydroxyl ions, occurring with the greater facility as the amount of alkali around the anode is less; it is quite independent of the presence or absence of ammoniocupric ions, and Traube and Biltz are mistaken in attributing any influence to the catalytic effect of the ammoniocupric compound. This discovery of the authors led at once to the observation that the conditions least favourable to the action $\text{NO}_2 \rightarrow \text{NO}_3$ were also those most favourable to the action $\text{NH}_2 \rightarrow \text{NO}_2$; but the influence of the ammonio cupric ion on this latter action has been thoroughly established by Traube and Biltz, to whom only the credit of the discovery is due.—J. T. D.

Tantalum; Temperature Coefficient of Resistance of —. F. Steintz. Z. Elektrochem. 1905, 11, 273–274.

It is pointed out that the temperature coefficient, determined by W. von Bolton between 0° and 100° C. to be 0.3, per cent. (this J., 1905, 1400) in comparison with other metals in the same periodic series, agrees with the author's conclusion that the temperature coefficient increases with rising atomic weight.—R. S. H.

Ceric Ammonium Nitrate; Electrolytic Preparation of —. G. Plancher and G. Barbieri. XX., page 558.

Molasses; Electrolytic Treatment of —. H. Claassen. XVI., page 554.

ENGLISH PATENTS.

Meter; Electrolytic —. S. H. Holden and Chamberlain and Hookham, Ltd., Birmingham. Eng. Pat. 13,223, June 11, 1904.

This invention relates to the type of meter in which the current is passed through an electrolyte, such as dilute sulphuric acid, and in which the loss of water by electrolysis is made a measure of the current passing through the meter. The vessel containing the electrolyte is

suspended from springs so as to form a spring balance, and by means of a rack and pinion, combined multiplying gear, the amount of electricity consumed is recorded on dials.—B. N.

Fan or Exhaustor; An Improved —, for the Electrification of Air or other Gases. F. de Marcy, Bru. Eng. Pat. 20,630, Sept. 21, 1904. Under Int. Conv., Sept. 24, 1903.

The fan is adapted to exhaust or compress a gas or vapour, and at the same time subject it to a high electric discharge. The casing, of insulating material, is made in two parts which are separated by a dielectric diaphragm, and within the casing a double series of blades or wings are fixed on an insulated shaft, and are adapted to be rotated for exhausting and propelling air or gas. An electric current passes from one series of blades to the other through the dielectric diaphragm during the passage of the gas through the fan.—B. N.

Gases and Vapours; Apparatus Operating with Automatic Regulation for Submitting — to the Action of the Electric Arc. O. Imray. From Soc. d'Etudes Electro-Chimiques, Geneva. Eng. Pat. 13,952, June 20, 1904.

This invention relates to an apparatus for effecting the self-regulation of electric arcs operating in the presence of gases or vapours, and enables the arcs to be maintained at the requisite low tension without danger of extinction. A number of pairs of electrodes are arranged in series, the electrodes being made horn-shaped or any other shape which enables the arc to vary its length by rising or falling along the same with increased or diminished electric pressure, and each pair of electrodes is arranged within a vertical tube acting automatically as a draught chamber for the gas to be treated.—B. N.

Alcohols, Aromatic, and their Derivatives; [Electrolytic] Process for Manufacturing —. C. Mettler. Fr. Pat. 348,951, Oct. 28, 1904. Under Int. Conv., July 15, 1903. XX., page 559.

(B.)—ELECTRO-METALLURGY.

ENGLISH PATENTS.

Metals; Apparatus for Electro-deposition of —. King, Newark, N.J. Eng. Pat. 28,601, Dec. 28, 1904.

This invention relates to the forms of apparatus, in which the electro-deposition of metals, in which a revolving container is provided with openings for the circulation of the electrolyte. The openings are made large so as to offer little resistance to the current, and in order to prevent the articles to be plated from dropping through these openings, an inner thin flexible diaphragm of cellulose, vulcanite, or similar material, provided with numerous fine holes, is made to conform to the inner contour of the container. The diaphragm may, if necessary, be made in sections to fit containers of any shape.—B. N.

Galvanising, Tinning or otherwise Plating Wire and other Metallic Bodies; Process of —. G. A. Goettl. Minneapolis, U.S.A. Eng. Pat. 3798, Feb. 23, 1905. Under Int. Conv., June 9, 1904.

The wire is brought into contact with molten plating metal,

the surfaces of contact are "electrically excited," an electric current being passed through the metal to be plated and through an attenuated mass of plating metal which it is submerged.—R. S. H.

UNITED STATES PATENTS.

Liquor; Utilising Spent — A. S. Ramage, Detroit, Mich. U.S. Pat. 788,061, April 25, 1905.

Iron dioxide is added to spent pickle liquor containing iron, and the liquor is electrolysed, an insoluble sulphur dioxide being used. Iron is deposited at the cathode, and sulphur dioxide is oxidised at the anode. The treated liquor is then again used in pickling iron.—U.S. Pat. 758,687, of May 3, 1904; this J., 1904, E. S.

Electrolytic Separation [Metal Deposition]; Method of — J. H. Hoopes, Pittsburg, Pa. U.S. Pat. 788,315, April 25, 1905.

Electrolysis of an anhydrous salt of the metal in anhydrous ammonia is electrolysed, the anode and cathodes of the cell being separated by a porous diaphragm. The solution is kept cold to prevent precipitation. Applications of the process to the separation of magnesium and to the refining of metals are mentioned.—R. S. H.

Method of Treating Surfaces; [Electrolytic] Method and Apparatus — T. A. Edison. Fr. Pat. 348,747, of April 10, 1904.

U.S. Pat. 26,947 of 1904; this J., 1905, 201.—T. F. B.

II.—FATTY OILS, FATS, WAXES, AND SOAP.

Carbon Tetrachloride as a Solvent for Fatty Acids — O. Brücke. Chem. Rev. Fett-u. Öl-Ind., 1905, 12, 100—102.

Carbon tetrachloride is now produced at a price that renders its being used extensively for the extraction of fatty acids from ordinary iron extraction apparatus used for the extraction of fatty acids with petroleum spirit has proved quite unsuitable. The new solvent, and it has yet to be determined if it is the most suitable material and mode of extraction. The advantages offered by the extraction of fatty acids with carbon tetrachloride are as follows: The solvent is superior in colour and odour, and will fetch about 100 per cent. more than the fat extracted with petroleum spirit, which always retains the smell of the solvent, whereas the odour of the carbon tetrachloride is completely expelled by means of steam. Moreover, petroleum spirit dissolves malodorous products of decomposition, which is stated not to be the case with carbon tetrachloride. It is further stated that no organic compounds dissolve in carbon tetrachloride, owing to the lower temperature of extraction, the bones are better suited for the manufacture of fatty acids, giving both a higher yield and a better product. Ordinary high premiums for fire insurance and precautions against fire are obviated. There is a great saving in steam and cooling water. Experiments made on the large scale show that there is a saving of 5 to 6 kilos. of solvent on each 1000 kilos. of bones extracted, which at the present price of carbon tetrachloride represents a loss of three to four marks.—C. A. M.

Vegetable; Purification of — C. Niegemann. Chem.-Zeit., 1905, 29, 465—466.

Algem. Chem.-Zeit., 1905, 100) found that when vegetable oil was exposed to temperatures of 5° to 35° C., the separation of the whole of the proteid impurities that cause turbidity did not occur until after four weeks, but that complete separation occurred after 24 hours to a few days at 4° C. was sufficient for their complete separation, only a small proportion of the precipitated substances being redissolved

on heating the oil. He attributed the more general occurrence of turbidity in oils of late year to the more thorough grinding of the seeds, and to the expedient of being sent out without having been stored. The author now finds that only a few minutes' exposure of oils to a low temperature is required for the complete separation of the impurities, and the purification can thus be carried out in one continuous operation, the long storage already being unnecessary. The temperature required to effect this result and that most suitable for the filtration of the oil must be separately determined for each individual oil. The occurrence of turbidity has hitherto not been of very frequent occurrence in edible oil, owing to the latter being cold-drawn. The deposited impurities are only soluble again to a small extent in the case of such oils, including cold-drawn linseed oil, and this is the explanation of Benz's conclusion of the insolubility of the separated substances. Linseed oil that has been expressed at a moderately high temperature soon becomes turbid, and even after storage and filtration will still yield fresh deposits, whilst oil expressed at the usual temperature of 70° to 80° C. yields still more pronounced deposits. This is notably the case with oil as expressed in some works where the slimy residue from the filtration of the oil through the bags is mixed with a fresh portion of crushed seed, usually after preliminary heating, and again pressed. This is said to cause a large portion of the proteid impurities to be dissolved by the oil, for the substances that are deposited in oil obtained by hot expression, will dissolve again to a large extent. In large works using filter-presses, the conditions are more favourable, and the oil does not become turbid so readily. Benz confirmed the author's conclusion that the separated substances were of a pectinous and proteid nature. The composition of Thomson's deposit (this J., 1903, 1005) which contained 47.79 per cent. of ash and only 1 per cent. of nitrogen is attributed by the author to the washing with ether and petroleum spirit, in which about 80 per cent. of the proteid deposit from linseed oil is soluble. Moreover, the oil obtained by extracting linseed with these solvents contains a large proportion of proteid impurities.—C. A. M.

Oleic Acid; Technical Separation of — from Solid Fatty Acids, by means of Petroleum Spirit and Alcohol. K. W. Charitschkoff. Chem. Rev. Fett-u. Harz-Ind., 1905, 12, 106—109.

FROM experiments on a small scale the author concludes that treatment of a mixture of oleic and solid fatty acids with petroleum spirit (sp. gr. 0.672) at 0° C., effects a fractionation of which the first fraction is a snowy white product of high melting point, whilst the final one is stated to be practically oleic acid with only a very small amount of solid fatty acids. Thus 1.55 grms. of the mixed fatty acids from a fat when treated in this way with 200 c.c. of the solvent gave a residue which was collected on a filter and washed with a smaller amount of petroleum spirit, thus being separated into two fractions (1) and (2). The original filtrate was evaporated and the residue treated with 100 c.c. of the solvent at 0° C., thus giving two fractions 3 and 4.

Fraction.	Weight.	Melting Point.	Solidification Point.	Iodine Value.
	Grms.	°C.	°C.	
1	18	58.0	57.0	—
2	9	39.5	38.5	90.0
3	35	46.8	45.6	80.1
4	51	30.8	30.2	90.1

In the author's opinion the first fraction was superior to that obtained by the ordinary method of separation by filter-presses. The solubility of pure stearic acid in petroleum spirit (of sp. gr. 0.672) at 0° C., was found to be 0.4 per cent. Its solubility in dilute alcohol (0.886 sp. gr.) at the same temperature was 0.11 per cent. Alcohol thus effects a more complete separation of the solid fatty acids, but unlike petroleum spirit, does not dissolve the

colouring matters. In practice therefore it is advisable to treat the fatty acids with alcohol first and then to remove the colour by a subsequent treatment with petroleum spirit.—C. A. M.

Soap; New Process of Preparing Soda [Sodium Bicarbonate] intended for the Manufacture of —. C. Ferrier. Fr. Pat. 348,708, Dec. 9, 1904.

SODIUM bicarbonate as obtained in the first stage of the ordinary ammonia-soda process is applied directly in the manufacture of soap. The fat is heated in a closed boiler, to which the bicarbonate, mingled with sodium chloride solution, is added, the mixture being boiled. The carbon dioxide evolved is collected for use in the manufacture of fresh sodium bicarbonate. Finally, a small proportion of caustic soda is added to complete the saturation of the fatty acids, and to decompose any ammonium salts in the residual lye.—E. S.

FRENCH PATENT.

Gum Resins; [Electrical] Treatment of —, and Residual Product ["Sylvine"]. A. Nodon. Fr. Pat. 348,653, Feb. 16, 1904.

THE gum-resins are mixed with potash or soda lye and the mixture is distilled, the heating being effected electrically. The charge is placed in an earthenware retort, the bottom of which is covered with a sheet of iron, and a second layer of iron gauze is placed on the surface of the charge. A potential difference of 110 volts is maintained between the two metallic sheets. The turpentine obtained by this method is said to be superior in quantity and quality to that obtained by heating, and the residue in the retort, for which the "Sylvine" is proposed, is said to be completely soluble in water and forms a serviceable soap.—M. J. S.

Resinous Products; Apparatus for the Distillation of —. G. Col. First Addition, dated Nov. 15, 1904, to Fr. Pat. 342,425, April 18, 1904 (this J., 1904, 943).

IN the present additional patent, claim is made for distilling the distillation apparatus described in the main patent.

vertical instead of in a horizontal position; and also use of a double-walled monteius provided inside with a screen, the surface of which is cleaned by a rotating brush. The crude resinous matter is melted in the monteius and then transferred by compressed air or the steam to the distillation apparatus, whilst the ligneous matters, &c., are held back by the screen.—A. S.

(C).—INDIA-RUBBER, Etc.

rubber; Microscopic Examination of — P. Breuil. *Comptes rend.*, 1905, 140, 1142—1143.

Experiments of the rubber in carbon bisulphide or other solvents were allowed to evaporate on microscopic slides. The case of non-vulcanised rubbers containing sulphur, which show branching lines due to the sulphur, and also for the same rubber whatever may have been the solvent. The same appearance is obtained when a trace of sulphur in carbon bisulphide is slowly evaporated. With vulcanised rubbers the sulphur appears to be in centres from which lines radiate, to a greater extent as the temperature to which the rubber has been subjected is higher and has been longer maintained; these radiating lines interlace with one another forming a kind of network. Similar appearances are shown by the thin sections of rubber obtained by distending bicycle air-tubes. The carbon and ebonite surfaces, polished and etched by potassium permanganate and examined by reflected light, also show a network appearance; no doubt the lines are the same as those noted above, which have been attacked differently from the rest of the surface. Gutta-percha under the microscope shows a granular structure, the fineness and uniformity of which appears to be connected with the nature of the gutta-percha.—J. T. D.

rubber; Swelling of — in *Carbon Bisulphide*. *Gummi-Zeit.*, 1905, 19, 578—580; 608—this J., 1904, 794 and 943; 1905, 448).

Raw Para rubber "swells," or enters into a partial solution, less readily than pure dimethyloctadiene, but much more so than when dry and freed from resins. Moist raw Para forms an emulsion, which in earlier stages contains a larger percentage of water than when dry Para is used, but this percentage diminishes later on, the rubber not dissolving completely further. The same applies also to moistened caoutchouc. When freed from resins the rate of swelling varies with the degree of polymerisation; swelling proceeds with greater rapidity in proportion to resin content increases. The more resin is present in the variety, the more easily such a specimen will be made to "swell" in carbon bisulphide. The structure of caoutchouc retards swelling, so that masticated caoutchouc turgescens more quickly than dried raw Para; mastication changes both the structure and polymerisation of the substance. Pure dimethyloctadiene swells more readily than masticated dry Para. It

is prepared according to the known method by solution (swelling) of Para rubber in chloroform and precipitation with absolute alcohol, the Para having first been freed from resins by treatment with acetone in the Soxhlet apparatus (*Berichte*, 1902, 35, 3261). The solution (swelling) and precipitation are repeated six times. A small proportion of oxygen does not appreciably affect the tendency to swell in carbon bisulphide. Turgescence is increased by agitation. Warmth accelerates swelling, but retards solution; and as its action is probably one of depolymerisation, it would appear that multiplication of the $C_{10}H_{16}$ molecule retards swelling but facilitates solution. The degree of elasticity of any one kind of caoutchouc does not influence the curve of turgescence, when moderate thicknesses are in question. Elasticity probably depends mainly on the degree of polymerisation; and the experiments with Madagascar and Para rubber seem to indicate that higher polymerisation is accompanied by increased elasticity.—C. S.

ENGLISH PATENT.

Rubber; Process for Reclaiming and Regenerating — L. T. Petersen, Akron, U.S.A. Eng. Pat. 28,294, Dec. 23, 1904. Under Int. Conv., June 24, 1904.

SEE U.S. Pat. 774,727 of 1904; this J., 1904, 1155.—T. F. B.

UNITED STATES PATENT.

Rubber; Cleaning — W. A. Lawrence, Assignor to Continental Rubber Co., New York. U.S. Pat. 787,518, April 18, 1905.

The impure rubber is ground with water, subjected to a hot-water bath, and the floating impurities removed by means of a blast of air directed against the surface of the water. The residual rubber and woody impurities are then immersed in a liquid, such as salt water, having a density greater than that of the rubber, until the woody impurities sink to the bottom; the rubber, which floats to the surface is removed.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Barks, Woods, &c.; Analyses of Cuban and Argentine — L. E. Levi and J. F. Sigel. *Hide and Leather*, 1905, 12, 38.

The increasing scarcity of hemlock bark in America has caused tanners to look further afield for a suitable substitute. The authors have made analyses of a number of Cuban and Argentine barks, woods, and fruits that were exhibited at the St. Louis Exhibition, with the following results:—

XV.—MANURES, Etc.

Calcium Cyanamide; Application of Peat to the Conversion of. — into Ammonium Compounds. R. Perotti. Atti R. Accad. dei Lincei Roma, 1905, 14, 174—177. Chem. Centr., 1905, 1, 1181.

THE author has previously pointed out (this J., 1905, 143) that calcium cyanamide must undergo decomposition in the soil, before it is capable of acting as a fertiliser. Experiments were made with a calcium cyanamide fertiliser containing 9.35 per cent. of calcium cyanamide, and 15.4 per cent. of nitrogen; and peat containing 83.83 per cent. of humus-substances and 1.31 per cent. of nitrogen. On treating mixtures of: (1) 250 grms. of the fertiliser and 250 grms. of peat; (2) 125 grms. of the fertiliser and 375 grms. of peat; each with 300 c.c. of foul water, the calcium cyanamide was rapidly hydrolysed without appreciable loss of nitrogen. The course of the hydrolysis was followed by means of determinations of the calcium cyanamide and water. It was found that with the mixture containing only 25 per cent. of calcium cyanamide, this was decomposed in four days, whilst in the other mixture the decomposition was complete after two to three months. The author recommends for technical purposes the admixture of peat with fertilisers containing calcium cyanamide, in order to convert the latter into directly assimilable ammonium compounds.—A. S.

Calcium Cyanamide. W. Zielstorff. Bied. Centr., 34, 217—218; from Illustr. Landw. Zeit., 1904, 1103.

By applying calcium cyanamide some days before sowing the seed, the nitrogen value of the manure was increased to 92.8 (sodium nitrate=100), the value being 85.4 when the seed was sown immediately after the manure.

Calcium cyanamide should not be applied as a dressing. Like sodium nitrate, the manure has very little after-effect.—N. H. J. M.

Perchlorates and Chlorates; Determination of. — Sodium Nitrate. D. Tschernobajeff. XXIII., page 1.

XVI.—SUGAR, STARCH, GUM, Etc.

Molasses; Electrolytic Treatment of. — H. Claus. Z. Ver. Deutsch. Zucker Ind., 1905, 446—448.

THE author comes to the conclusion that the electrolytic treatment of molasses has as little chance of becoming a profitable operation as the similar treatment of juice. On the other hand, the electrolytic treatment of molasses-residues gives better promise of success, provided that a market can be found for the organic acids obtained.—W. P. S.

Apricot Gum. P. Lemeland. J. Pharm. Chim., 21, 443—448.

THE gum exuded by the apricot tree is usually of a brilliant amber colour, generally opaque, and is characterised by a brilliant conchoidal fracture. Two specimens examined by the author, one collected in 1896, the other in 1904, gave a loss of about 16 per cent. on drying at 10°C., and contained about 76 per cent. of matter soluble in water. By heating the gum with nitric acid of strength 1.15, it yielded mucic acid, corresponding with 15.53 and 15.53 per cent. of galactose respectively (calculated on the original substance). Pentosans were determined by Tollens' method, and amounted to 40.75 and 38.4 per cent. respectively. Fifteen grms. of the gum were heated in an autoclave at 110°C., with 100 c.c. of 5 per cent. sulphuric acid. The excess of acid was neutralised and the non-hydrolysable portion of the gum precipitated with alcohol. From the solution left, L-arabinose was isolated by means of its benzylphenylhydrazone.—B. F.

nd Woody Fibre in the Sugar Cane and in Bagasse :
mination of — H. and L. Pellet. Bull. Assoc.
Sucr. Dist., 1905, 22, 921—936.

ight of experience gained with Egyptian canes the
g conclusions are stated with regard to the analy-
termination of sucrose and fibre in the sugar cane
bagasse. The cane fibre offers a very different
ze to pressing according to the conditions under
he cane has been grown. While some canes may
to 73 per cent. by weight of juice at the first
under the same conditions other canes will
y 55 to 56 per cent. The direct determination of
the cane, if whole canes be taken, does not give
average richness of a crop of canes, owing to the
a in the composition of the cane from one stalk
er, and of canes from different fields. The richness
ane can be approximately deduced only by the
method. The direct determination of the sugar
ne may be effected with a certain approximation
ies working by diffusion, the division of the cane
settes allowing of the taking of a true average

The determination of sugar in the fresh cossettes
ided cane can be accomplished only by taking a
rge weight, at least 50 grms., and treating it by
e exhaustions with boiling water (say six times).
nal treatment for control. The same observations
the bagasse. The alcoholic method can also be
l for the determination of sugar provided that
rial be finely divided by being first cut into thin
d then bruised in an iron mortar, and thoroughly
control exhaustion being made by a final treatment
and alcoholic extraction in a Soxhlet apparatus.
hors have shown, however, that for certain
as it was possible for a second control extraction
to sugar notwithstanding the presence of sucrose
aterial treated, in consequence of the resistance
ells to the diffusion of sugar in the presence of

The method of direct hot aqueous digestion does
exact results except under conditions in which the
ion of the samples is generally very difficult.
etermination of woody fibre in the cane, great care
taken in preparing an average sample, and alcohol
be used. Alcohol precipitates from the juice a
of organic and mineral matters which remain
fibre and increase its weight by about 0.30 to
cent. Sugar also, is less soluble in alcohol than
and unless all the precautions necessary in an
extraction are taken, sugar and the ordinary
as which are associated with it in the juice may be
solved and increase the amount of fibre from
00 per cent. The use of alcohol should therefore
d from cane sugar factories as it practically
beetroot sugar works. Specimens of cane fibre
ig equal percentages by weight of woody fibre
ways show the same resistance, or contain the
portion of cellulose.—L. J. DE W.

V.—BREWING, WINES, SPIRITS, Etc.

Products of the Autodigestion of Certain Varieties
— M. Schenck. Woch. f. Bran., 1905, 22,
1, 27.

hor allowed quantities of pure cultivated top-
tion beer yeast, distillery yeast and mycoderma
undergo auto-proteolysis in presence of chloro-
a temperature of 28° C., until the biuret reaction
longer be obtained. The digested liquids were
nected to a series of precipitations by group-
and the substances present in the various
ic were characterised as far as possible. The
ult of the investigation are summarised in a table, and
mped with those of a similar research on the products
tion of bottom-fermentation yeast by Kutscher
d L. mann. The substances identified as present in
stion products of all three varieties of yeast
Succinic acid (considerable quantities), lactic
rosine, leucine, adenine, hypoxanthine (traces),
acid, glutamic acid (doubtful traces in products

of distillery and mycoderma yeasts), lysine, choline, tetra-
methylenediamine. Histidine could not be detected, but
it has been recorded amongst the products from bottom-
fermentation yeast. Uraeil was detected in the products
from distillery and mycoderma yeasts, but not in those
from beer yeasts. On the other hand, arginine and
guanidine were present in the products from beer yeasts,
but absent from those from distillery and mycoderma
yeasts.

The digestion products of pure cultures of top-fermenta-
tion beer yeast and of distillery yeast showed the " trypto-
phane " reaction strongly, whereas those from cultures
of mycoderma yeast, free from culture yeasts, did not give
this reaction. The exhausted cell residues of the beer
yeast and the mycoderma yeast turned brown on exposure
to the air, but those of distillery yeast remained white. The
above observations might be utilised for the recognition
of the purity of cultures of mycoderma yeasts and distillery
yeasts respectively.—J. F. B.

Yeast : Production of Sulphuretted Hydrogen by —
H. Will. Z. ges. Brauw., 1905, 28, 285—287.

A CASE is described in which a beer of the Pilsener type
had a peculiar musty smell, due to sulphuretted hydrogen.
The cask-sediments blackened lead-paper distinctly.
After racking and long storage, the bad flavour of the
beer disappeared to a large extent. This beer was pre-
pared with a special variety of yeast propagated in the
form of a pure culture in a separate vessel. This yeast was
employed because of its property of developing a special
flavour characteristic of Pilsener beer, and when it was
first taken into use the results obtained were excellent.
The wort was strongly hopped and brewed with the addi-
tion of gypsum, but the development of the sulphuretted
hydrogen could not be attributed to any abnormalities
of the raw materials, because the same wort, when fer-
mented with other yeasts, showed scarcely a trace of
sulphuretted hydrogen. Neither was the trouble due
to infection. After an exhaustive investigation, the
conclusion is drawn that the production of sulphuretted
hydrogen is a normal characteristic of certain varieties
of culture yeast, although the quantity developed under
normal conditions can only be detected by a very expert
taster. But in this case the tendency was magnified by
a weakening or degeneration of the yeast by prolonged
cultivation in the propagating apparatus, resulting in a
starved or pathogenic condition peculiarly favourable to
the formation of sulphuretted hydrogen, the addition
of gypsum to the brewing water also possibly contributing
to this result.—J. F. B.

Yeast, Agglutination of — by Borates : Coagulation
Phenomena. H. van. Laer. Bull. Soc. Chim. de
Belg., 1905, 19, 31—47.

BORAX possesses the property of coagulating yeast, but
the coagulum disintegrates after a time which is pro-
portional to the excess of borax employed. This dis-
integration coincides with a disappearance of the alkaline
reaction, and the addition of sodium carbonate prevents
it; the tendency to disintegrate occurs only in the case
of living yeast. The phenomena of agglutination of yeast
present many analogies to the coagulation phenomena
of other colloids. There is a critical minimum proportion
of borax below which no coagulation takes place.
For a given suspension of yeast the quantity of borax
necessary to produce agglutination is proportional to
the volume of the yeast suspension. Brewery
yeasts require a larger proportion of borax than
bakers' yeasts. The tests are best made by suspending
250 grms. of pressed yeast in 500 c.c. of water, and adding
increasing quantities of a solution of 6.376 grms. of
anhydrous borax in a litre of water, to 10 c.c. of the yeast
mixture. The critical proportion of borax required for a
given yeast suspension is lower the lower the temperature
of the mixture. Yeast killed by boiling, requires, under
similar conditions more borax than living yeast for its
agglutination. Certain very flocculent yeasts resist
agglutination; this resistance can be overcome by the
addition of a little calcium chloride. Resistance to coagu-
lation is due to some extent to the acidity of the mixture
and can be overcome by the addition of sodium carbonate.

A clear solution of calcium borate agglutinates yeast in the same way as borax. The presence of salts of the heavy metals and of magnesium, increases the quantity of borax necessary for agglutination. In the case of yeasts which agglutinate readily with borax, the addition of calcium chloride has little effect. Beyond a certain variable limit of dilution the agglutinating power of borax is lost. The quantities of borax required for the agglutination of equal volumes of suspensions of the same yeast at different dilutions are proportional to the squares of the inter-cellular distances, the latter being proportional to the cube roots of the relative dilutions. A clot of yeast, even if prepared by an excess of borax, can consequently be disintegrated by diluting the system with water. Sodium aluminate has the same agglutinating properties as borax. J. F. B.

Beer and Metals. J. Brand. Z. ges. Brauw., 1905, 28, 237—240.

When sheet zinc is left in contact with pale lager beer in stoppered bottles, the beer remains clear for a long time, but its colour becomes appreciably paler, and hydrogen sulphide is formed in the beer owing to the reduction of either the sulphite present, or the organic compounds containing sulphur. The zinc goes into solution, and, after 16 hours, the beer exhibits a distinct metallic, astringent taste, which does not, however, increase in intensity even if the action is allowed to proceed for six days. When galvanised iron is covered with beer and allowed to remain at the ordinary temperature, the beer becomes slightly turbid after 16 hours, and the metallic taste and odour of hydrogen sulphide are of about the same intensity as with the sheet zinc; the mouldy smell, however, is much more marked than in the latter case. The metallic taste and the zinc-content of the beer continue to increase, and after three days, analysis showed that 100 c.c. of the beer contained 0.017 grm. of zinc; after this time the disagreeable odour was much less noticeable. No iron was found in solution. The rapid action of beer on galvanised iron is due to the loose consistency of the layer of zinc; this may be improved by adding small quantities of aluminium to the zinc.

Beer has a much greater action on iron than wort. In order to decide whether this is due to the presence of carbon dioxide in the beer, the author measured the action on iron of beer containing the normal proportion of carbon dioxide and of beer from which the gas has been expelled by boiling. After three days' action, the beer free from carbon dioxide contained 0.0108 grm. of iron per 100 c.c., and the other 0.0129 grm. The former becomes turbid much more rapidly than the latter; this is probably to be explained by the fact that the soluble iron compound in the beer precipitates certain albuminoid matters, which in the ordinary beer are carried to the surface by the gas and form a yellow scum, whilst they remain suspended in the beer free from gas. As the carbon dioxide in the beer appears to exert but little influence on its power of attacking iron, the action must be due mainly to the organic acids and the acid salts.

The author examined, with reference to their behaviour with beer, two samples of so-called "Neutral Iron," which is manufactured by the Ferrum Company in Zawodzie, near Kattowitz, and is very resistant to the action of acids. One of these samples (I.) was more resistant to acids, but also more brittle and difficult to work than the other (II.). Pieces of these samples, and one of ordinary iron (III.) of 20 sq. cm. area, were covered each with 100 c.c. of pale beer and left for three days. With I., the beer remained bright; with II., the beer exhibited a moderate turbidity, whilst with III., the beer was very turbid and had acquired a greyish-green colour. One litre of the beer contained the following amounts of iron:—I., 0.002; II., 0.028; III., 0.0996 grm.—T. H. P.

Brandy. P. Schidrowitz. J. Inst. Brewing, 1905, 11, 125—139.

THE best brandies are those produced in the Cognac districts, viz., Charente and Charente Inférieure; then follow in order of value those from Armagnac, Marmande,

POT STILL WITH SIMPLE RECTIFYING HEAD, ALAMBIC DE

Nantes and Anjou; the cheapest class is that known as "Montpellier." The mare brandies form a class themselves, those from the Burgundy districts coming high prices. Cognac brandy is generally made by system of double distillation, known as "brouillage," in simple pot-stills. The spirit is distilled slowly, a charge of 110 galls. occupying 8 hours. The first runnings come over at a strength of 60—65 per cent. of alcohol, rapidly rising to 70—75 per cent., and distillation is continued until the distillate consists of 75 per cent. of alcohol. The first distillate is sometimes divided into three fractions: the first has an alcoholic strength of 25—35 per cent., known as "brouillis." This is rectified during "repassage"; the first runnings, to the extent of 5 per cent. of the whole, are mixed with the next lot of "brouillis." The middle fraction, or fine spirit, over at a strength of 80—85 per cent. at first, and collected until the strength has fallen to about 66 per cent. The average strength of this spirit is 66—70 per cent. The residue is distilled until water passes over; this fraction is called "seconde," it has a strength of 50 per cent., and is either mixed with a fresh charge of alcohol or is rectified separately. In recent years simple pot stills have to a certain extent displaced the double distillation stills. Such a still, known as "Alambic de Nantes," is illustrated in the figure. The new stills enable the distiller to obtain the brandy in a single operation, and had the effect of extending the range of wines which can be employed for brandy manufacture, a result very desirable on account of the ravages of Phylloxera. It regards the extent to which rectification of a grape spirit may legitimately be carried, the author would make no restriction beyond that imposed by the necessity of depending only on the natural odour and taste of the wine for the flavour of the brandy. Passing to the question of the definition and chemical analysis of brandy, the author proposes to limit the term "brandy" to that distilled in France, the volatile constituents of which are derived entirely from the grape, and which contain no added matter of any kind excepting water, sugar, and colouring matter, and of which the taste and odour are those ordinarily associated with that designation. The question of analytical criteria must be approached with great caution, since the number of well authenticated analyses of genuine brandies is really very small; the tendency to base a judgment as to the genuineness of a sample of brandy upon the proportion of esters is emphatically condemned. A spirit 50 years old is in way comparable with one only five to six years old in the physiological properties of very old brandies, and only in a minor degree to the initial constituents of the spirit.—J. F. B.

Malt Analysis. J. S. Ford and J. M. Guthrie. J. Inst. Brewing, 1905, 11, 206—221.

FOR the determination of the diastatic power of malt, the authors describe the following method:—20 g. of finely-powdered malt, weighed out in the form of whole corns, are extracted with 500 c.c. of water in a boiling

is. After settling for 10–15 minutes, 1 c.c. of tered extract is added to 70 c.c. of a solution of starch (=2 grms. of dry starch) at 40° C. and ure is maintained at this temperature for 1 hour. on is then stopped by the addition of 1 c.c. of oda solution (10 grms. per litre), the mixture is iluted to 100 c.c. and the cupric-reducing power ained in 25 c.c. of the solution, using 30 c.c. of solution.

astatic power on Lintner's scale is calculated by ing the weight of cupric oxide per 100 c.c., after g for the reducing power of the starch by the 0.

uthors have also worked out a method for g the quantity of maltose produced during conversion polarimetrically. In this case trin (Brown and Morris) must be used instead of arch; the procedure in other respects resembles ribed above, the change of rotation being deter- place of the reducing power. The diastatic malt, when 2.5 c.c. of the above malt extract oyed per 100 c.c., is calculated on Lintner's multiplying the decrease in rotation in angular r sodium light in the 2 dem. tube by the factor

thors lay great stress on the necessity for the of all impurities of a metallic or alkaline nature solutions used in the analysis (see this J., 1904, e tests are conducted in vessels of Jena glass, ater employed is distilled in a special still with e.—J. F. B.

Straw Cellulose; Manufacture of — by the Sulphite Process. R. Dietz. Z. angew. Chem. 1905, 28, 648–653.

THE siliceous nature of straw has hitherto stood in the way of a satisfactory isolation of the cellulose by the bisulphite process. The proportion of silica in different varieties of straw varies between 1.5 and 3.7 per cent. Experiments have shown that the treatment of the straw with the theoretical quantity of hydrofluoric acid, calculated on the basis of the silica-contents of the straw, in the form of a 0.5–1.25 per cent. solution, is capable of reducing the proportion of silica to less than 0.05 per cent. In this form the straw is quite suitable for treatment by the bisulphite process. The waste liquors from the hydrofluoric acid extraction can be passed into streams without injury to fish, if they are diluted in the proportion of one part to 70; precipitation with lime will also make these liquors harmless. The author has worked out on

a small scale the best conditions for boiling the purified straw. An ordinary calcium bisulphite liquor, as employed for wool, has given good results. Such a liquor contains 3.6 per cent. of total sulphur dioxide; 2.4 per cent. being "free" and 1.2 per cent. combined. The proportion of liquor to straw should be reduced as much as possible, in order to avoid excessive action. If the straw be well packed it can be covered with 1.5 times its weight of liquor. The boiling should be regulated so that a pressure of 3.5 atmospheres is reached in one hour, and this should be maintained for three hours. The waste liquor should contain 0.15 per cent. of sulphur dioxide. The yield of cellulose obtained is about 42 per cent. It is of excellent quality and bleaches well in two treatments, with a consumption of 13 per cent. of bleaching powder. The bisulphite process modified in the above manner offers many advantages over the older soda process in the case of straw.—J. F. B.

UNITED STATES PATENT.

Paper Coating. F. X. Govers, Owego, N.Y. U.S. Pat. 788,043, April 25, 1905.

THE coating composition contains 20 parts of saponified vegetable wax, 50 parts of casein, one part of alkali, 100 parts of water, and 600 parts of a mineral base. The saponified wax should contain a certain proportion of wax in the unsaponified condition.—J. F. B.

Pulp; Apparatus for Treating Filter — R. Birkholz, Milwaukee, Wis. Assignor to E. Goldman & Co., Chicago. U.S. Pat. 787,971, April 25, 1905.

THE apparatus consists of a mixer situated in the filter-cellar, a pump connected with the mixer, a pulp-washing machine situated on a floor above the mixer, and supplied with pulp from the mixer by means of the pump, and lastly a draining-chest in the filter-cellar into which the washed pulp is discharged. Different forms of washing machines are described: they are provided with stirrers, water- and steam-supplies and washing screens either fixed or rotary.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Ceric Ammonium Nitrate; Electrolytic Preparation of — G. Plancher and G. Barbieri. Atti R. Accad. dei Lincei Roma, 1905, 14, 119—120. Chem. Centr., 1905, 1, 1975—1976.

CERIC-AMMONIUM nitrate, which is made use of in the separation of cerium from lanthanum, neodymium, praseodymium and samarium, cannot be easily prepared by mixing together solutions of ceric and ammonium nitrates. The authors prepared it by electrolytic oxidation of a concentrated solution of cerous-ammonium nitrate rendered strongly acid with nitric acid, using a piece of sheet platinum as anode surrounding a porous cell containing a platinum wire cathode immersed in nitric acid. By using a current strength of 0.1—0.2 ampère per sq. dm. of anode surface, the cerous salt was oxidised quantitatively to ceric-ammonium nitrate.—A. S.

Mercuric Acetate in Glacial Acetic Acid; Reactions of Certain Substances with Ethylene Bonds with a Solution of — Formation of Resorcinol Mercuric-mercuri-acetate and Triacetyl-mercuric-phloroglucinol. A. Leys. J. Pharm. Chim., 1905, 21, 358—396.

THE reagent is prepared by heating 3 or 4 grms. of mercuric oxide or 10 grms. of mercuric acetate to boiling in 100 c.c. of glacial acetic acid; on cooling, the excess of mercuric acetate crystallises out; the mother liquor is decanted and furnishes the reagent. It keeps well at ordinary temperatures, but, after boiling for half an hour under a reflux condenser, it deposits, on cooling, crystals of mercurous acetate. Prolonged boiling should therefore be avoided. Phenols should first be boiled with a little glacial acetic acid and then cooled before being added to the reagent. Monohydric phenols,

their derivatives and monovalent acids, give no marked reaction, but with more complex phenols definite compounds are formed.

With *resorcinol* a deep yellow glistening precipitate is formed between 60°—70° C., which increases in quantity as the temperature rises to the boiling point. This is mercuric-mercuri-acetoresorcinol $C_6H_3O_2Hg.Hg.COOC_2H_5$.

Phloroglucinol under similar conditions forms a yellow precipitate of triacetomercuric-phloroglucinol $C_6H_3(O.Hg.O.CO.CH_3)_3$. Both these bodies are insoluble in most solvents.—J. O. B.

Ether; Oxidising Action of Impure — H. Ber. 1905, 38, 1409—1410.

THE blue solution of cobaltous oxide in highly concentrated potassium hydroxide solution is decolorised by formation of a brown precipitate, on addition of drops of impure ether. It is not decolorised by pure ether, and only after some time by addition of a hydrogen peroxide solution. It is therefore probable that the action of the impure ether, in this case, is a more active oxidising agent than hydrogen peroxide, probably ethyl peroxide, thus bearing out the conclusion of A. J. Rossolimo (this J., 1905, 288).—E. F.

Glycerolphosphates; Analysis of — Reidel's Ber. 1905, 73—75. Z. angew. Chem., 1905, 18, 62.

IN the examination of glycerolphosphates, tests have been made for uncombined phosphoric acid, free glycerolphosphates, chlorides, barium, heavy metals, and an (which has been recently detected) in quantities ranging from traces up to 3.5 per cent.). Comparative determinations of the phosphoric acid in glycerolphosphates by the usual gravimetric process and by Astruc's volumetric method (this J., 1898, 179) showed that the latter gives good results in the case of alkali glycerolphosphates, but figures several per cent. too high with the calcium magnesium salts.—A. S.

Gynocardin, a New Cyanogenetic Glucoside. F. B. and F. H. Lees. Chem. Soc. Trans., 1905, 87, 341.

POWER and Gornall (Chem. Soc. Proc., 1904, 21, 137) have previously shown that when the seeds of *Gynocardia odorata* (R. Br.) are crushed and brought into contact with water, hydrogen cyanide is formed, owing to the presence in the seeds of a cyanogenetic glucoside, which was isolated and designated *gynocardin*. The authors have prepared a larger quantity of the glucoside, and attempted to determine its constitution. Four kilo-powdered *gynocardia* seeds were first extracted with petroleum for the complete removal of the fatty matter, then with 95 per cent. alcohol. On expelling the alcohol from the extract, a dark syrupy residue was obtained, which soon formed a paste consisting chiefly of a crystalline substance; this was separated from the mother-liquor, digested for several minutes with warm acetic acid, and again separated. A further quantity of the glucoside was obtained from the syrupy mother-liquor, by first mixing it with "prepared" dust, drying the mass and extracting it with ethyl alcohol, which slowly removes the glucoside. The crude glucoside was purified by dissolving it in water, treating the solution with animal charcoal, and evaporating under diminished pressure to a syrup, which set to a hard cake of crystals which were dried on porous earthenware. The yield was 200 grms. *Gynocardin* forms colourless, glistening, prismatic needles of the composition $C_{13}H_{19}O_9N + 1\frac{1}{2}H_2O$; the water is expelled at 100° C. The anhydrous compound melts at 162°—163° C., and has the optical rotation $[\alpha]_D^{21} = +72.5^\circ$ in aqueous solution.

It is readily hydrolysed at the ordinary temperature by *gynocardase*, an enzyme contained in the seeds, but only with difficulty by boiling with 5 per cent. hydrochloric sulphuric acid. Dextrose and hydrogen cyanide are isolated from the products of the reaction, but the substance, $C_6H_8O_4$, which should be produced, according to the equation:

$C_{13}H_{19}O_9N + H_2O = C_6H_{12}O_6 + C_6H_8O_4 + HCN$ is decomposed by secondary reactions. *Gynocardin* is

other known cyanogenetic glucosides (this J., 1901, 1902, 996; 1903, 1255) in its relatively great activity towards acid hydrolysing agents. It is hydrolysed by treatment with barium hydroxide solution, and the barium salt of *gynocardinic acid*, $\text{O}_9\text{CO}_2\text{H}$, being formed, according to the equation:

It forms dextrose and an acid, $\text{C}_5\text{H}_{10}\text{O}_6$, on hydrolysis with acids. The results obtained indicate that it is the dextrose ether of the cyanohydrin of a α -oxy-aldehyde or-ketone in accordance with one of the following formulae:

The enzyme *gynocardase* was isolated by treating the ground seeds with light petroleum to remove the oil, and then digesting them with water at the ordinary temperature for 24 hours. The filtered liquid yielded with twice its volume of alcohol, and, after standing for some hours, the precipitate was filtered off, washed with alcohol and dried *in vacuo* over sulphuric acid. It was two per cent. of the weight of the seeds.

—A. S.

Oil. Ziegelmann. Pharm. Rev., 1905, 280. Chem. and Druggist, 1905, 66, 612.

It was distilled 43 kilos. of savin with steam, and 4-7.3 grms. of essential oil floating on the surface was recovered, whilst by extracting the water with petroleum further 17.34 grms. of oil was recovered. The first oil had the sp. gr. 0.91329 and the second, 0.91331. The oil was optically inactive; it had an acid value of about 10 and an ester value corresponding to about 40 per cent. ethyl acetate.

It was pointed out that the U.S.P. requires savin oil to be obtained from the ends of the branches of *Juniperus communis*; in Belgium the fresh leaves are distilled, in Greece the twigs, in Spain the leaves and fruits, and in some countries, the entire plant is subjected to distillation.

barbituric Acid: Process of Making —. M. Elberfeld, Elberfeld. Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 787,360, April 1905.

DIAMIDE is condensed with the dinitrile of a malonic acid, in presence of an alkaline condensing agent (e.g., an alkali alcoholate), forming 2-cyanimino-5-dialkylpyrimidine. The cyanimino and alkyl groups are removed from this latter compound by treatment with acids (e.g., hot dilute sulphuric acids), barbituric acids being thus produced.—T. F. B.

Active Matter, and Process of Making same. H. B. New York. U.S. Pat. 787,928, April 25, 1905.

ACTIVE matter, solid or liquid, is prepared by heating thorium below red heat, separating the thorium emanations from the thorium from which they were obtained, and passing these emanations through a porous matter so as to impregnate the whole. (See S. Pat. 788,480, page 557.)—J. F. B.

FRENCH PATENTS.

Alcohols, Aromatic, and their Derivatives: [Electrolytic] Process for Manufacturing —. C. Dutcher, Fr. Pat. 348,951, Oct. 28, 1901. Under Int. Conv., July 15, 1901.

ESTERS of aromatic carboxylic acids may be reduced electrolytically in presence of mineral acids, the products of reduction being the corresponding alcohol and ether; thus, the reduction of ethyl benzoate gives rise to a mixture of benzyl alcohol and benzyl ethyl ether, the proportions of the final product being dependent on the conditions of the reaction. The following is an example of the process: A solution of ethyl benzoate, 300 grms., alcohol (96°), 600 grms., sulphuric acid, 350 grms., and water, 100 grms., is submitted to electrolysis in the cathode compartment of a suitable apparatus, the anode compartment containing dilute sulphuric acid; the electrodes are of pure lead, and a current density of about 7 amperes per 100 sq. cm. of cathode surface is employed. The temperature of the solution is kept between 20° and 30° C. When reduction is complete, the solution is made alkaline, and the oily layer is separated, dried, and fractionated.—T. F. B.

Alcohols: Method of Synthesising Monatomic and Polyatomic —. V. Grignard. Fr. Pat. 348,957, Nov. 10, 1904. Under Int. Conv., March 4, 1901.

By the reaction of organomagnesium halides with halogen derivatives of alcohols (using 1 mol. of the magnesium derivative for each hydroxyl group present in the alcohol) and decomposing the resulting products with water, alcohols are obtained which contain the organic radical of the magnesium compound in place of the halogen in the halogenated alcohol employed; for instance, the interaction of phenylmagnesium bromide and monochlorhydrin gives rise to the formation of the compound $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{OMgBr}$, which, on decomposition with water, yields phenylethyl alcohol. T. F. B.

GERMAN PATENTS.

Saponin: Preparation of a Non-poisonous — from the Bark, Leaves, Stems and Roots of *Balanis Sarmienti* and *Guaicum*. E. Merck. Ger. Pat. 156,954, Feb. 13, 1903.

THE acid saponin is precipitated from an aqueous extract of *Balanis Sarmienti* or *guaicum*, the filtrate is treated with basic lead acetate, and the product is decomposed by means of sulphuretted hydrogen. The resulting saponin is neutral and non-poisonous, having only a small solvent action on red blood cells. Its composition is represented by the formula $\text{C}_{22}\text{H}_{36}\text{O}_{10}$.—T. F. B.

Glycollic Acids of Pyrogallol and its Alkyl Ethers: Process for Preparing the —. Act.-Ges. f. Anilinfabr. Ger. Pat. 155,568, Feb. 27, 1903.

THE glycollic acids of pyrogallol or of its mono- or dialkyl ethers are prepared by the action of monochloroacetic acid on pyrogallol, &c., in presence of alkali. Pyrogallol mono-, di-, or tri-glycollic acids, pyrogallol monoalkyl ether mono- or diglycollic acids, and pyrogallol dialkyl ether monoglycollic acids can be obtained by this process. They all possess the property of developing the latent photographic image, and may also be utilised for the production of dyestuffs or for medicinal purposes.—T. F. B.

Castor Oil in the form of a dry Powder [with Magnesium Carbonate]: Process for Obtaining —. D. Wasserczug. Ger. Pat. 156,999, April 3, 1903.

ONE part of castor oil is thoroughly mixed with one part of magnesium carbonate and one part of water, the water is evaporated, and the resulting mass pulverised. It is stated that a dry powder is obtained by this method, suitable for medicinal purposes.—T. F. B.

Fatty Acids: Preparation of Monochloro-derivatives of —. H. Blanck. Ger. Pat. 157,816, June 7, 1903.

FOR the preparation of their monochloro-derivatives, fatty acids are heated, in presence of their chlorides or anhydrides, with sulphuryl chloride to a temperature below the boiling point of the latter. The chlorination is stated to proceed quantitatively.—A. S.

Methyl [o-Tolyl] Alkyl Ethers; Process for Preparing the Alkyl Ethers of an Aromatic — Farbwerke vorm. F. Bayer und Co., Ger. Pat. 154,658, Aug. 2, 1903.

THE ethers of o-tolylalcohol are obtained by the interaction of equimolecular weights of the double compound of benzyl magnesium halides with ester and of halogen-methylalkyl ethers of the composition XCH_2OR , when X represents a halogen and R an alkyl radical. The resulting ethers are stated to be applicable to primary and also as intermediate products for the preparation of pharmaceutical compounds. — T. F. B.

o-Chlorophenol; Process for Preparing — W. Lossen, Ger. Pat. 155,631, Aug. 14, 1903.

ORTHOCHLOROPHENOL is prepared by the interaction of equimolecular weights of phenol and chlorine in presence of carbon tetrachloride or similar indifferent solvent, the mixture being strongly cooled during the reaction. — T. F. B.

S-Aminothioxyphyllic Acid and its Alkyl or Aryl Derivatives; Preparation of — C. F. Boehringer and Soehne, Ger. Pat. 156,904, Sept. 2, 1903.

S-AMINOTHIOPHYLLINE and its alkyl or aryl derivatives are produced by the action of ammonia or primary or secondary amines on S-chlorothiophylline. — T. F. B.

Paraxanthine; Process for Preparing the S-Amino Derivatives of — C. F. Boehringer and Soehne, Ger. Pat. 156,901, Sept. 2, 1903. Addition to Ger. Pat. 156,900 (see preceding abstract).

THE S-amino-derivatives of paraxanthine are prepared from S-chloroparaxanthine by the action of ammonia or amines. — T. F. B.

Cyanodialkylacetylureas; Process for Preparing — E. Merck, Ger. Pat. 156,383, Nov. 1, 1903.

CYANODIALKYLACETYLUREAS of the general formula $\text{N}(\text{C}(\text{R}')\text{R}')\text{CO.NH.CX.NHR}$,

where X may be oxygen, sulphur, or NH, which find application in the manufacture of barbituric acid derivatives, are obtained by condensing dialkylcyanooacetic esters with the corresponding urea derivative in presence of a metal alcoholate at the ordinary temperature. — T. F. B.

p-Allylphenol Alkyl Ethers; Process for Preparing — A. Verley, Ger. Pat. 154,654, Nov. 23, 1902.

THE alkylethers of p-allylphenol are obtained by the reaction of an alkyl halide on the compound obtained by the action of magnesium on a p-bromophenol alkyl ether. The mixture is heated under a reflux condenser, the ether is distilled off, and the product fractionated. The resulting p-allylphenol ethers are converted by means of alcoholic potash into the corresponding propenyl compounds. — T. F. B.

Peptone Salt; Preparation of a Halogen Acid — Kalle und Co., Ger. Pat. 156,399, Nov. 29, 1903.

OLIGOMER PEPTONE is treated with a halogen acid, and the product is washed with a dilute alkali carbonate solution until it ceases to exhibit an acid reaction. — T. F. B.

Aminoketones of the Constitution $(\text{HO})_2\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{CH}_2\text{N}(\text{X})_2$; Process for Preparing — Farbwerke vorm. Meister, Loeb and Brünig, Ger. Pat. 157,399, Dec. 25, 1903.

STRUCTURAL FORMULAS of the general constitution $(\text{HO})_2\text{C}_6\text{H}_3\text{CH}(\text{OH})\text{CH}_2\text{N}(\text{X})_2$,

where X represents a hydrogen or alkyl radical, are obtained by the reduction of the aminoketone compounds described in Eng. Pat. 26,480 of 1903 (see this J., 1904, 1913). The reduction may be carried out electrolytically, or by means of sodium amalgam, or by any other suitable method. — T. F. B.

GERMAN PATENTS.

Types of the Cyanine Series; Process for the Preparation of Sensitizing — [for Photographic Purposes], Act.-Ges. f. Anilinfabr., Ger. Pat. 155,541, June 5, 1903.

CYANINE dyestuffs which extend the colour sensitiveness

of photographic plates further towards the red end of spectrum than those known at present, are obtained by oxidising methyl derivatives of quinoline alkyl halides the methyl group being in the pyridine nucleus (quinoline, lepidine); one only of these compounds may be used, or a mixture of two of them, or a mixture of one of them with a quinoline alkyl halide. For example, 20 grms. of quinoline iodomethylate are dissolved in 500 cc. of water, and oxidised with 25 grms. of potassium ferricyanide and 50 cc. of "concentrated" caustic solution; the dyestuff is extracted from the product by means of ether. Quinoline alkyl halides alone give no dyestuffs on oxidation. — T. F. B.

Glycollic Acids of Pyrogallol and its Alkyl Ethers; Process for Preparing the — [Photographic Development], Act.-Ges. f. Anilinfabr., Ger. Pat. 155,568, Feb. 1903. XX., page 559.

FRENCH PATENT.

Explosives; Process of Manufacturing — A. M. Jacobs, Fr. Pat. 348,807, Dec. 13, 1904. SEE U.S. Pat. 777,125 of 1904; this J., 1905, 44. — T. F. B.

XXIII. — ANALYTICAL CHEMISTRY.

APPARATUS, Etc.

Heating Substances in a Vacuum at a Constant Temperature; Apparatus for — W. R. Hodgkinson and A. H. Coote, Chem. News, 1905, 91, 194.

apparatus which is shown in the adjoining figure has been used for the stability test for gun cotton. The heating vessel, and contains a liquid of constant boiling-point. (For gun cotton testing it is surrounded by wire gauze screen.) C is a tube containing the substance to be heated. B shows how C is connected to the rest of the apparatus by an india-rubber ring. C is wedged in between the two tubes and moistened with glycerin. The gas is measured over water or mercury and may be collected for analysis by means of the T.—C. E. F.

INORGANIC QUANTITATIVE.

Stes; Oxidation of — by Iodine in Alkaline Solution. R. H. Ashley. Amer. J. Science, Silliman, 5, 19, 237—239. Chem. Centr., 1905, 1, 1047.

(this J., 1902, 1473) has proposed the oxidation of ions of sulphurous acid or sulphites by treatment with acidified solution of iodine in presence of sodium borate, and the determination of the excess of iodine reaction with thiosulphate solution. The author finds, however, that the oxidation of thiosulphate by iodine in the solution proceeds further than the formation of boronate, so that more than the theoretical amount of iodine is consumed. On the other hand, under the conditions given by Rupp, the oxidation of the sulphite ion is not complete, so that his approximately correct results were evidently due to a fortunate compensation of error by another tending in the opposite direction. It seems probable that a similar compensation of errors occurs in the determination of phosphoric acid by Ruppink's method (this J., 1902, 1473).—A. S.

ne, Bromine, and Iodine; Separation of —, one another in Mixtures of Chlorides, Bromides, Iodides. O. Wentzki. Z. angew. Chem., 1905, 696—698.

The principle of the method is that mercurous bromide, when shaken with a soluble iodide, completely decomposes the latter, forming mercurous iodide and a soluble chloride, whilst mercurous chloride behaves similarly with bromides (and *a fortiori* with soluble iodides). The author's experiments have shown the method to be applicable to the haloid salts of potassium, sodium, ammonium, magnesium, barium, strontium, and calcium. The results are as follows:—In 100 c.c. of a solution of mixed iodide and iodide (containing, say, 1—2 grms. per litre of each salt), the weight of mixed silver halide is determined, by precipitating with excess of silver nitrate. In 300 c.c. of the same solution are placed in a glass-stoppered flask, successive small amounts of precipitated silver iodide, and the mixture shaken well after each addition. When the reaction is thought to be complete, 100 c.c. of calomel will be needed for 0.127 gm. of silver iodide, a small quantity is filtered, some calomel added, the mixture shaken and allowed to subside; the undissolved settled solid is compared with that of a similar quantity of calomel in distilled water—the merest trace of iodine is indicated by a yellow colour. If the reaction is thought to be incomplete, the portion filtered off is returned to the main quantity, and more calomel added. When the reaction is complete, the solution is filtered through a filter, and the silver chloride formed determined by precipitation of 100 c.c. of the filtrate with excess of silver nitrate. From this weight, and that of the silver halides above, the amount of chlorine and iodine present are readily calculated. The separation of chlorine from bromine is carried out in exactly a similar manner, while bromine is separated from iodine by treatment of the mixed solutions with mercurous bromide instead of calomel, testing the filtrate for iodine by means of nitrous acid and chloroform. As a whole three are present together, determinations are made of the silver precipitate from 100 c.c. (1) direct, (2) after precipitation of 300 c.c. of the solution with mercurous bromide ($x\text{AgCl} + (y+z)\text{AgI}$); (3) after precipitation of 300 c.c. with mercurous chloride ($(y+z)\text{AgCl}$). The results show a satisfactory accuracy in the last case.—J. T. D.

Potassium Permanganate in the Presence of Potassium Persulphate; Determination of —. J. A. N. Friend. Chem. Soc. Proc., 1905, 21, 133.

In order to obtain accurate results in the volumetric determination of small quantities of potassium permanganate in the presence of potassium persulphate (up to 0.08 gm.), the solution should be diluted to at least 150 c.c., and only a very slight excess of potassium iodide and acid added.—A. S.

Perchlorates and Chlorates; Determination of — in Sodium Nitrate. D. Tschernobajeff. Chem.-Zeit., 1905, 29, 442—443.

A METHOD for the determination of perchlorates in sodium nitrate was suggested by H. Lemaître (Monit. Scient., 1904, 18, 253). He reduced the perchlorate to chloride by melting the sample with sodium sulphite, dissolved the melt in water, precipitated with barium nitrate, filtered, and precipitated the filtrate with sodium persulphate. After neutralising with acetic acid, the sodium chloride was titrated with silver nitrate, using potassium chromate as indicator. The author found that the reduction in this process is complete, but that the sodium nitrite formed interferes somewhat in the titration. He recommends dissolving the melt in about 100 c.c. of water, adding an excess of N/20-silver nitrate solution and 6 c.c. of concentrated nitric acid, heating the solution almost to boiling for half an hour, filtering off the silver chloride and titrating the filtrate with N/20-potassium thiocyanate solution with a ferric salt as indicator. For the determination of sodium chlorate and iodate, which are equally reduced by sodium sulphite, the author employs Hendrixson's method (this J., 1904, 951), *viz.*, reduction by metallic iron in sulphuric acid solution at ordinary temperature. Using 0.3—0.4 gm. of iron powder and 10 c.c. of sulphuric acid (1:3) he obtained complete reduction of about 0.1—0.2 gm. of sodium chlorate mixed with nitrate after 15—20 minutes. The iodate being present in the natural nitrate in very small quantity may be neglected.

—R. L.

Lead-Potassium Sulphate; Existence of a Definite — [Determination of Lead]. F. C. Belton. Chem. News, 1905, 91, 191.

THE determination of lead as sulphate in presence of potassium salts often leads to too high results. The author finds that this is due to the formation of a lead-potassium sulphate. In order to obtain accurate determinations of the lead in such cases, he recommends that the precipitation of the lead as sulphate should take place at a boiling heat, and that excess of sulphuric acid be used.

To prepare lead-potassium sulphate, $\text{K}_2\text{Pb}(\text{SO}_4)_2$, 30 c.c. of a 10 per cent. solution of lead nitrate are slowly added to 20 c.c. of a saturated solution of potassium sulphate at 75°C. After digesting for five minutes at 75°C., the solution is filtered through a Gooch crucible, washed with a saturated solution of potassium sulphate, and then once with cold distilled water.—C. E. F.

Vanadium; Method of Determining —, and its Application to Metallurgical Products. E. Campagne. Monit. Scient., 1905, 19, 331—358.

AN amount of the vanadium compound which contains not more than 0.1 gm. of vanadium is evaporated with 50 c.c. of hydrochloric acid, and the treatment repeated twice, when it is stated, all the vanadium will be present as divanadyl chloride, $\text{V}_2\text{O}_4(\text{Cl})_2$. This is converted into the sulphate by heating with concentrated sulphuric acid, and the solution is diluted to 250 c.c. to 300 c.c. and titrated with potassium permanganate solution, a convenient strength for which is about 1 gm. per litre. In the application of this method to vanadiferous minerals or alloys, the substance is decomposed by heating with nitric acid, and the residue heated to convert the nitrates into oxides, which are then dissolved in hydrochloric acid. Iron is separated from the solution of the chlorides by Rothe's ether extraction method (see this J., 1892, 946). Alloys which contain copper or nickel as well as vanadium are attacked in the same manner, and the copper or nickel

is removed from the chloride solution by electrolysis. Silica is removed by filtering the sulphate solution just previous to titrating.—T. F. B.

ORGANIC QUALITATIVE.

Hydrocyanic Acid: Phenolphthalin as a Reagent for —, F. Weehuizen. Pharm. Weekblad., 1905, 42, 271-272. Chem. Centr., 1905, 1, 1191.

If an alkaline solution of phenolphthalin, together with a 1:2000 solution of copper sulphate be added to a solution of hydrocyanic acid, a red coloration is produced in the cold, the phenolphthalin being oxidised to phenolphthalein. A perceptible coloration is produced in a solution containing 1 of hydrocyanic acid per 500,000.

Turpentine Oil: Examination of —, Utz. Chem. Rev., Fett-u Harz Ind., 1905, 12, 99-100.

A DETERMINATION of the refractive index of that portion of commercial turpentine oil which remains insoluble in fuming sulphuric acid may afford valuable indications of the nature of a sample, especially when considered in conjunction with the amount of this insoluble portion (Herzfeld's test). Thus a turpentine oil with refractive index of 1.4723 at 15° C. yielded 1.8 c.c. of a portion insoluble in sulphuric acid, and one of 1.6 c.c. insoluble in fuming sulphuric acid, and the second residue had a refractive index of 1.4944. The same oil mixed with 10 per cent. of a turpentine oil substitute yielded an insoluble portion of 2.2 c.c. with sulphuric acid and one of 1.5 c.c. with fuming sulphuric acid, the refractive index of the latter being 1.4672. A Russian turpentine oil yielded similar insoluble portions of 1 c.c. and 0.6 c.c. respectively, and the second had a refractive index of 1.4956. The same oil mixed with 10 per cent. of petroleum distillate yielded products having the following corresponding values:—2.4 c.c., 1.8 c.c. and 1.4544. Certain turpentine oils, notably those of German origin, give no further separation with fuming sulphuric acid, and in such cases the first portion separated by ordinary sulphuric acid, should be taken. Thus, a rectified turpentine oil treated with sulphuric acid yielded 0.9 c.c. of insoluble matter with a refractive index of 1.5108 at 15° C. For the detection of pine oil products it has been recommended that the substance should be shaken with an equal volume of sulphurous acid solution (yellowish green colour of the upper pine oil layer). The author confirms the fact that in this test American turpentine oil gives a snow-white emulsion which separates very slowly; rectified turpentine oil of the German Pharmacopoeia behaves in a similar manner, though the separation into layers is more rapid. Turpentine oil substitutes (benzol preparations and petroleum distillates) give no colours. The substance that gives the coloration can be separated by repeated distillation of pine oil, being left behind in the residue. Stannous chloride solution (Bettendorff's reagent) affords another means of distinguishing between turpentine oil and pine oil. The sample is shaken with an equal volume of the reagent and the colour observed. With Austrian turpentine oil the reagent becomes yellow and the oil remains colourless; whilst with Greek turpentine oil and American turpentine oil the reagent becomes orange and the oil yellow. On the other hand pine oil colours the stannous chloride solution raspberry red, whilst the oil itself usually remains yellow, though in some cases it, too, becomes raspberry-red. Certain samples of pine oil then give Lyon's reaction (a dark brown or black coloration with concentrated hydrochloric acid).—C. A. M.

Butter: Detection of Coconut Fat in —, Wanters. Bull. Soc. Chim. de Belg., 1905, 19, 6-7.

THE presence of coconut fat in butter can be detected by an examination of the crystalline form of the product with a polarising microscope. Coconut fat crystallises in long needles, frequently united in the form of a leaf or fan, whilst butter-fat crystallises in round masses which show a very characteristic cross in polarised light. Coconut fat having a very low critical temperature of solution and a low Reichert-Meißl value, the sum of these two

constants is also very low. The presence of cocoanut in butter therefore lowers this sum considerably, e.g. pure butter-fats the value is about 84, but the add of 10 per cent. of cocoanut fat lowers it to 80, refractometer number and the quantity of fixed acids are no longer in accordance with the Reichert-M value. The presence of cocoanut fat also lowers critical temperature of solution and the refractor number of the fixed fatty acids.—J. F. B.

Quinine and Cinchonine: Reaction for Distinguish- between —, C. Reichard. Pharm.-Zeit., 1905, 314. Chem.-Zeit., 1905, 29, Rep., 122.

THE alkaloid is treated in the cold with a mixture of concentrated sulphuric acid and ammonium molybdate gently with a few crystals of ammonium sulphate, and then treated with a 40 per cent. solution of formaldehyde and a drop of a strong solution of ammonium thiocyanate. The dark blue colour produced by treatment with sulphuric acid and ammonium molybdate changes to yellow on heating with ammonium persulphate. On adding the potassium thiocyanate solution, the mixture is coloured an intense reddish-brown if cinchonine is present, whilst if only quinine be present, either no reaction takes place or the mixture becomes faintly red after a time.—A. S.

Aconitine: New Reaction for —, E. P. Alvarez. Chem. News, 1905, 91, 179-180.

IN the examination of a specimen of pure aconitine, the coloration with sucrose and sulphuric acid was not obtained. The alkaloid was readily saponified by caustic potash, but no formation of veratrine could be detected. The new reaction for pure aconitine is as follows:—The alkaloid (0.0005-0.0002 gm.) is warmed with 5-10 drops of pure bromine, 1-2 c.c. of fuming nitric acid are added, and the mixture evaporated to dryness, with the addition of a little more bromine necessary. From 0.5 to 1 c.c. of a saturated alcoholic solution of caustic potash is then added, and the mixture evaporated to dryness; the residue has a more or less intense brown or red colour according to the quantity of aconitine present. After cooling, 5-6 drops of an aqueous 10 per cent. solution of copper sulphate are added, the solution soon acquires a deep green colour, if aconitine be present.—A. S.

ORGANIC QUANTITATIVE.

Carbon and Hydrogen in Organic Compounds: Determination of —, F. Pregl. Ber., 1905, 38, 1-1444.

THE object of the method is to enable a combustion to be performed automatically without personal attention beyond the necessary initial and final weighings, and the initial adjustment of the apparatus. The part of the combustion-tube, furthest from the absorption apparatus, is left empty. The next 30 c.m. are filled with copper-oxide-asbestos, followed by 6 c.m. of lead peroxide, to a nitrogen oxides, halogens, &c. In the case of compounds containing iodine, the last portion of the copper-oxide-asbestos must be replaced by silver-asbestos. The end of the tube nearest the absorption apparatus, which is an ordinary type, is heated to 150°-180° C. in an air-bath. The copper-oxide-asbestos portion is heated by five fixed Fletcher burners. The substance to be analysed is placed in a boat, behind which a diffusion plug is inserted, and is heated by a single burner which is made to travel from the end, towards the absorption apparatus, slowly and steadily, by means of clock-work. A horizontal asbestos screen travels just above the combustion boat with the movable burner, and so concentrates the heat effect. The combustion is carried out in a slow stream of oxygen. After starting the combustion no further attention is necessary, except to finally drive out the oxygen by air, and perform the final weighings. The speed of the movable burner can be initially adjusted according to the nature of the substance to be analysed. For further particulars, especially with regard to the method of filling the tube, the original paper must be consulted.—E. F.

d Groups; Simple Method for the Determination of — J. J. Sudborough and W. Thomas. Chem. c. Proc., 1905, 21, 88.

0.5 to 1 grm. of the acetyl derivative is treated with per cent. solution of pure benzenesulphonic acid apthalene- *a*- or β -sulphonic acid), and the mixture with steam until the distillate is no longer acid. Distillate is then titrated with a standardised solution of barium hydroxide, using phenolphthalein as indicator. *O*-acetyl compounds the distillation takes from one to two hours, but somewhat longer with *N*-acetyl derivatives. The pure benzenesulphonic acid used can be purified by blowing steam through a solution of the barium salt until the distillate is neutral, then allowing the solution to crystallise, and decomposing the purified barium salt with the theoretical quantity of sulphuric acid.—A. S.

s; Determination of the Water and Free Caustic Alkali in — K. Braun. Z. angew. Chem., 1905, 58, 573–574.

A weighed quantity of the finely-divided soap is dried to constant weight in a wide-necked flask fitted with a U-tube containing soda-lime. The soda-lime prevents access of carbon dioxide of the air, and thus the conversion of free caustic alkali into carbonate during the drying is avoided. The dried soap is dissolved in the smallest possible quantity of alcohol, and the free alkali determined by titration, using phenolphthalein as indicator. —A. S.

Malt Analysis. J. S. Ford and J. M. Guthrie. XVII., page 556.

Alcohol in Beer; Determination of — by the Zeiss Immersion Refractometer. E. Ackermann und A. Steinmann. Z. ges. Brauw., 1905, 28, 259–260.

Good agreement is obtained between the strengths of aqueous alcohol as given by Wiedemann's tables from the specific gravity and by Wagner's tables from the refractometer number obtained by the Zeiss immersion instrument; the differences amount to about 0.2 per cent. for solutions containing from 0 to 6 per cent. of alcohol and to about 0.3 per cent. for those with from 6 to 10 per cent. It is found that the alcohol content of a solution is proportional to its refractive index except between 6 and 7 per cent., where the ratio suddenly changes to another value, at which it then remains constant. It was not found possible to draw up an exact table for the refractometric determination of alcohol in wines, probably owing to the influence exerted on the refraction by the volatile acids and aromatic substances.

With beer distillates, however, much better results are obtainable, as is shown by a large number of estimations carried out by the authors. Since Wagner's tables were not calculated for beer distillates, the authors have prepared a new table, giving the percentage of alcohol present in the distillate for all refractometer numbers from 15.0 to 23.5.

Table for the Determination of the Alcohol-content of Beer Distillates from the Refraction by Means of the Zeiss Immersion Refractometer at 17.5° C.

Analysis; Use of the Centrifugal Machine in — B. Bordas and Touplain. Comptes rend., 1905, 140, 108–1099.

The authors show that the fat is completely extracted from cocoa by digesting the latter with ether and subjecting the mixture to centrifugal action, the extraction separation being repeated three times, and taking the residue left after removing the fat, as above, is treated with water and centrifuged to obtain the sugar. With chocolate, a little trisodium phosphate must be added, after extracting the fat, to keep the casein in solution.—W. P. S.

Rapid Method for the Analysis of — F. Bordas and Touplain. Comptes rend., 1905, 140, 1099–1100.

5 c.c. of the milk are added, drop by drop, to a mixture of 65 per cent. alcohol and a little acetic acid contained in a test tube. After standing a short time the tube and contents are subjected to centrifugal action. The supernatant liquid is then decanted off, the precipitate is treated with 30 c.c. of 50 per cent. alcohol, again subjected to centrifugal action and the solution decanted. These

solutions are united and the ketose determined by Fehling's method. The residue left in the tube is extracted twice with a mixture consisting of 2 c.c. of 96 per cent. alcohol and 30 c.c. of ether, and the ethereal layer separated each time in the centrifugal machine and decanted. The mixed ethereal solutions are then evaporated in a weighed flask, and the residue of fat weighed. The finely-powdered casein left in the tube is weighed after being dried. A determination of the ash in a separate test tube. The milk completes the analysis. In the case of curdled milk, the whole sample is measured, separated into two layers by centrifugal action, and each layer separately analysed.—W. P. S.

Lemon Oil; Indirect Method of Determining the Aldehydes in — E. Berté. Chem. and Druggist, 1905, 66, 682–684.

It is proposed to calculate the total amount of aldehydes present in lemon oil from the optical rotation of the oil before and after the removal of the aldehydes, the percentage being given by the expression $100(A-a)/A$, where *a* is the rotation of the original oil, and *A* that of the oil free from aldehydes. The aldehydes may be removed,

for example, by boiling 10 c.c. of the oil with 50 c.c. of a saturated solution of potassium bisulphite, under 5 mm. pressure. In preliminary experiments it was found that prolonged heating with reagents that removed aldehydes did not modify the rotation of the terpenes. This method was found to furnish accurate results when applied to mixtures of pure citral and monenes of known composition.

—F. F. B.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Gold. Precipitation of — in the Crystalline Form.
R. Dykes. Chem. News, 1905, 91, 180.

On evaporating an ether solution of uranium nitrate and auric chloride, the solution, towards the end, changed from pale yellow to orange-red, and became viscous; on adding a few drops of distilled water and again evaporating, a bright yellow scintillating precipitate formed. On repeating the experiment, amorphous gold was obtained. In one case and sealy gold in another, but on adding a few drops of auric chloride solution to the filtered liquid and again evaporating, a crystalline precipitate was obtained. In one experiment the gold was obtained in crystals only after repeated evaporation and the frequent addition of auric chloride. Crystals of gold were also obtained by keeping an ether solution of auric chloride in a sealed tube for some days in the dark.—A. S.

Silver. Gold obtained —. A. Gauthier and G. Hofmeier.
Z. anorg. Chem., 1905, 45, 77–80.

SOLUTIONS containing 50 c.c. of 1 per cent. gum arabic solution were made up to 200 c.c. by addition of 0.1 per cent. silver nitrate solution and water, the amounts of silver nitrate solution being 100, 25, 10, 5, and 1½ c.c. respectively; after reduction by a 0.05 per cent. solution of hydrazine hydrate, the solutions were dialysed, and then proved to be all very stable, showing no sign of precipitation even after 3 months. They could even be concentrated by careful evaporation, and *in vacuo* over sulphuric acid at the ordinary temperature could be dried to dark glass-like solids, completely soluble again in warm water. They were readily destroyed by shaking with animal charcoal or barium sulphate. About 95 per cent. of the quantity of silver used, was recovered in these hydrosols. The colours of the solutions were as follows:—

Volume of Silver Solution in 200 c.c.	Colour by Reflected Light.	Colour by Transmitted Light.
100 c.c.	dark olive green	brown red
25	olive green	red
10	brownish	dark violet
5	grey	violet
1½	weak grey; appears turbid	in thick layers weak violet

Neither hydrogen peroxide nor formic acid could be used for the reduction. Ammoniacal silver nitrate reduced by phenylhydrazine sulphate, gave a hydrosol having a black colour by reflected, but appearing dark green by transmitted light; possibly there is here simultaneous formation of Blake's "blue" and "yellow" silver. Hypophosphorous acid, used to reduce silver nitrate in presence of gum arabic, gave a light-brown colour, turning dark-brown and then deep red; on gradually heating to boiling, the colour became olive-green (deep red by transmitted light), and this colour remained permanent after dialysis.—J. T. D.

Arsenious Anhydride Crystals; Light emitted by —
D. Gernez. Comptes rend., 1905, 140, 1134–1136.

THE author has investigated this phenomenon, and finds that the light is emitted, not, as is usually supposed, at the moment of separation of the crystal from the liquid, but when through contact with a hard body, rupture of the crystal occurs. It is, in fact, a case of tribolumin-

escence. It is not necessary that the acid solution of anhydride should have been boiled; moreover the crystals retain for weeks or months the property of emitting light when broken by rubbing with a glass rod. Nor need anhydride which is dissolved be originally in the vitreous form; the pulverulent crystallised anhydride, dissolved in hot hydrochloric acid, gives, on cooling, crystals which show the phenomenon just as strongly as those from the solution of the vitreous variety.—J. T. D.

Carbon; Separation of — from Carbon Dioxide
K. Brunner. Ber., 1905, 38, 1432.

THE separation of carbon from carbon dioxide is shown by burning magnesium powder in a dish formed of solid carbon dioxide. A grey cake is formed, which on treatment with dilute hydrochloric acid, is seen to be deep black, flocculent carbon. If the magnesium be replaced in this experiment by aluminium powder, aluminium oxide, soluble with difficulty, a little aluminium carbide and heavy graphitic carbon, are formed.—E. F.

Hydroxyl and Alkoxyl Groups; Influence of — on Velocity of Saponification. I. A. Findlay and W. E. Turner. Chem. Soc. Proc., 1905, 21, 127–128.

THE accelerating influence exerted by the hydroxyl group is shown by the following values for the saponification constant (*k*) in aqueous solution at 25° C.:—Ethyl phenylacetate, $C_6H_5.CH_2.CO_2C_2H_5$, 12.4; methyl mandelate, $C_6H_5.CH(OH).CO_2CH_3$, 157; ethyl mandelate, $C_6H_5.CH(OH).CO_2C_2H_5$, 66; propyl mandelate, $C_6H_5.CH(OH).CO_2C_3H_7$, 55; ethyl phenylmethoxyacetate, $C_6H_5.CH(OC_2H_5).CO_2C_2H_5$, 23.3; ethyl phenylethoxyacetate, $C_6H_5.CH(OC_2H_5).CO_2C_2H_5$, 157; and ethyl phenylpropoxyacetate, $C_6H_5.CH(OC_3H_7).CO_2C_2H_5$ (calculated from the values obtained in alcoholic solution) 13.2. The results also show that on substituting alkyl group for the hydrogen of the hydroxyl, the velocity of saponification is diminished, the diminution increasing regularly with the mass of the alkyl group.

The saponification constants of the esters mentioned above, in 30 per cent. and 60 per cent. alcohol, shown in the following table:—

Ester.	In 30 per cent. Alcohol. <i>k</i> .	In 60 per cent. Alcohol. <i>k</i> .
Ethyl phenylacetate	8.6	[6.0]
Methyl mandelate	[109.0]	[84.0]
Ethyl mandelate	49.4	29.1
Propyl mandelate	39.5	22.7
Ethyl phenylmethoxyacetate	15.2	[8.0]
Ethyl phenylethoxyacetate	10.2	[6.0]
Ethyl phenylpropoxyacetate	—	[5.0]

The numbers enclosed in brackets are only approximate in the case of the esters to which they apply, there was a gradual decrease in the value of the "constant" with time.

—A. S.

Trade Report.

1.—GENERAL.

BRITISH INDIA; TRADE OF —.

Chem. and Drug., March 13, 1905.

THE India Office has issued its annual Blue-book tables relating to the trade of British India with British Possessions and Foreign Countries, 1899–1900 to 1903. The present return contains statistics of the foreign trade during the last five financial years, and gives details of imports and exports. The book is published at 1s. by Messrs. Wyman and Sons, and the Government booksellers in Dublin and Edinburgh.

		Imports.		Exports and Re-exports	
		1902-3.	1903-4.	1902-3.	1903-4.
Alum.	lbs.	221,230	232,494	3,024	21,187

Chlorine	"	—	—	410,622	392,114

Blue-book also gives tables of imports of articles, showing principal countries, from which one is to see the source of the chemicals, drugs, and so on. Following are the figures for the United Kingdom for the five years:—

	1899-1900.	1900-1.	1901-2.	1902-3.	1903-4.
Alum.	£ 250,883	£ 312,316	£ 317,652	£ 295,977	£ 315,867
Ad. medi.	188,040	219,096	207,711	215,881	221,369
Alum.	96,813	102,623	105,980	131,769	157,488
Alum. cwt.	94,455	95,558	97,185	128,132	155,201

Ally all the alum, sodium bicarbonate, borax, making chemicals, copperas, sal ammoniac and ic acid were shipped direct from the United m. Sicily supplied the sulphur and Hong-Kong ina the arsenic, of which 2,380 cwt. was imported. lk of the camphor was obtained from Japan and aits Settlements. Cocaine appears in the list for t time, and of the quinine 46,692 lb. was obtained eat Britain, 2,234 lb. from Belgium, 904 lb. from A., and 2,033 lb. from other countries. India is consumer of saffron, which practically all comes rance direct. Of spirit used in the manufacture s, medicines, or chemicals, India imported 72,952 uring 1903-4, compared with 72,233 galls. during The U.K. supplied 57,787 galls. (57,240 galls. in and Germany 3,320 galls. (3,087 galls. in 1902-3). ed spirit was imported to the extent of 24,815 galls., ease of 6,600 galls. on the previous year. The upplied 11,259 galls. (9,103 galls. in 1902-3). and y shipped 5,921 galls. (4,622 galls. in 1902-3). derable decrease is noticed in the imports of methyl- pirit, only 40,566 galls. (4,652) having been d, against 91,352 galls. (9,837) in 1902-3. Germany largest share of the business, having sent 32,761 57,091 galls. in 1902-3). Austria-Hungary shipped galls. (19,721 galls. in 1902-3), and other countries.

which included the U.K., exported only 1,398 galls., or 13,000 galls. less than in 1902-3. Germany has the bulk of the trade in gum arabic, her imports during 1903-4 being 19,000 cwt. out of 39,000 cwt., this comparing with 10,029 cwt. for the United Kingdom.

GERMAN INDUSTRIAL STOCK COMPANIES' DIVIDENDS OF —.

For. Off. Ann. Series, No. 3342.

The following table shows the dividends declared by some Industrial Stock Companies in the German Empire during the year 1904:—

Industry.	Dividends. Per Cent.
Chemical	13-92
Porcelain, glass, pottery	11-82
Brewing and distilling	10-0
Sugar	9-35
Mining and smelting	8-68
Paper and rubber	8-23
Cement	6-53
Textiles	5-36

NOTE.—All higher than in 1903, except textiles.

POLAND; CHEMICAL INDUSTRY OF —.

For. Off. Ann. Series, No. 3351.

The chemical industry in this Consular district was not very successful in 1904. In consequence of the diminution of production in the cotton and woollen industries, the consumption of different chemical products for dyeing and printing was reduced to a minimum.

The production of sulphuric acid was regulated by agreement between the producers, who raised the price and lessened the production to about one-half the quantity they are capable of producing. This measure is very prejudicial to the other branches of the chemical industry, for which the price of sulphuric acid is of essential significance.

Both sulphur, in the form of pyrites, and common salt, are burdened with a relatively high import duty. Pyrites is not exploited in the Russian Empire, and has to be imported from Spain and Germany; whilst salt, being only found in Poland in small quantity at Ciechoćmek, has either to be brought from the north of the Crimea, whence the transport is excessively expensive, or imported from Germany, in which case there is a crushing duty of 28. per cwt.

The difference between the duty on intermediate products and on a great many synthetic organic dyes has enabled some German firms to establish in Poland several small factories which carry out processes for which they use the intermediate products of their chief houses in Germany. By the new tariff, however, a change will be made in this respect, as a great many of these organic products which have hitherto paid the duty on "chemical products not separately designated" at the rate of 11s. 9d. per cwt., will, by the new tariff, have to pay a special duty, which will be in many cases double or more. The synthetic dye industry will therefore have either to extend their scope of work and produce the necessary products, or to give up some of their articles.

The new tariff is also favourable to the production of some mineral colours (white lead and zinc), and for the preparation of mercury, which has hitherto been exported as a metal and re-imported in the form of its products. There is also a whole series of pharmaceutical productions which ought to develop considerably, thanks to the imposition of a higher duty in the new tariff.

A great drawback to the chemical industry in Russia is the system of patents, by which foreigners, especially Germans, hold patents for inventions in Russia which prevents others from making use of this form of production, of which, however, they do not themselves make use in Russia.

Until last year ether, for which there is a considerable demand in this Consular district, was imported from Germany, but at the end of 1904 an ether factory was started in the government of Piotrkoff, with a production of 30,000 lb. a year; but as this is far from covering the demand, several distillers in the government of Kalisz have combined for the production of ether on a larger scale.

MEXICO: EXEMPTIONS FROM IMPORT DUTY.

Bd. of Trade J., May 11, 1905.

The following articles are exempt from import duty under Articles 13, 14 and 15 of a new Mexican Law dated March 25, 1905.

Tariff

- No.
- 295 Zinc, in ingots, filings, powder, or wire.
- 303 Zinc, in sheets, not exceeding 1 by 2½ metres in length and breadth, and 1 millimetre in thickness.
- 358 Sulphur.
- 654 Sulphuric acid.
- 677 Alkaline cyanides.
- 697 Hyposulphite of soda.
- 716 Saltpetre, or nitrate of potash or of soda.
- 719 Sulphate of copper.
- 800 Machinery imported by mining or metallurgical establishments in which the precious metals are refined.

The above-mentioned provisions of this law were to take effect from May 1.

VII.—ACIDS, ALKALIS, Etc.

BILBAO, SPAIN: CHEMICAL INDUSTRY IN —.

For. Off. Ann. Series, No. 3352.

The native production of sulphate of ammonia is advancing very notably, as a consequence of the greater consumption. The local output is so small in proportion to the demand that its price has risen to about 450 pesetas (13l. 10s.) per ton. It is chiefly used in beet cultivation. For the same reason the price of nitrate of soda has also advanced. The local production is about 2,400 tons,

whilst the import of both these articles is estimated about 48,000 tons of the first and 30,000 tons of the second, the former coming wholly from the United Kingdom. The best markets are in the south of Spain, at Valencia. The native production of carbonate of soda and caustic soda has been so far of little importance, a Belgian company is erecting works at Torre (Santander province) to work the Solvay process, and calculates its future annual output at 20,000 tons of carbonate of soda—an amount equal to the present consumption and 15,000 tons of caustic soda. Sulphuric and nitric acids are almost wholly produced in the country, with the exception of small quantities of superior quality. New works are being erected close to Bilbao capable of producing 5,000 tons per annum by the contact process. Juice and products of a like nature are no longer exported but are used in native works for the production of tannic acid. Phosphates are imported from North Africa, Algiers, according to the quality or strength required. The importation of superphosphates has increased. Some come from France, Belgium and the United Kingdom, but the production in the country in old establishments as well as in new works is also augmenting. The importation of nitrate of soda from Chile is increasing as well as the indirect *via* the United Kingdom Germany.

VIII.—GLASS, POTTERY AND EARTHENWARE.

CORUNDUM ORE CONCENTRATES; U.S. CUSTOMS DECISION. April 28, 1905.

Corundum ore concentrates, which, on chemical analysis, was found to be ground corundum, was held to be dutiable as "emery ground or pulverised," at 1 cent per lb., under paragraph 419 of the present tariff. The claim of importer for free entry under paragraph 550, as "corundum," was overruled.—R. W. M.

IX.—BUILDING MATERIALS, Etc.

CEMENT IN THE UNITED STATES.

For. Off. Ann. Series, No. 3353.

The value of the imports of cement into New York again fallen from 75,000l. in 1903 to 24,000l. in 1904, and the total imports into the United States have decreased in the same period from 605,000l. to 277,000l. The report on the production of cement in the United States in 1903 showed that the total production of hydraulic cement was about 29,900,000 barrels, showing an increase of over 4,000,000 barrels as compared with 1902. Of these, 22,350,000 barrels were Portland cement, 7,050,000 barrels natural rock cement and 526,000 barrels Pozzolana or slag cement. The increase in the production of Portland cement resulted in a glutted market, a large quantity remained over at the close of the year 1903, and prices fell in consequence. Pennsylvania is the largest producer, having seventeen works with an out-turn in 1903 of 9,754,000 barrels. In New Jersey there are three works which produce 2,700,000 barrels and in New York three works with a production of 1,603,000 barrels. In 1904 the trade was greatly depressed; one of the works in New Jersey closed till the demand should improve and others were working on short time. The price fell to 85 c. (3s. 6½d.) per barrel, but at a meeting of manufacturers in December it was resolved to raise it to 1 dollar as to avoid working at a loss.

CEMENT INDUSTRY OF STETTIN.

For. Off. Ann. Series, No. 3358.

The year 1904 was not a very successful one for the cement industry. The very low prices ruling caused a considerable increase in the sales, but although demand remained good, prices did not revive owing to over-production in certain parts of Germany.

The total export of cement from Stettin by sea was 89,955 tons in 1903, and 88,869 tons in 1904, the greater part of which went to the Zollverein ports.

The small decrease is said to be due to the improvement

cement produced in the receiving countries, which is in a better position to supply their own demand. Export to the United States of America is also handled by the high import duty levied on cement.

"Kraft" Ironworks at Kratzwiek, near Stettin, fully employed during the year and all products a ready sale.

Portland cement was in good demand, but prices very low. The following were among the products manufactured in 1903-04:—

	Quantity.	
	1903.	1904.
..... tons	40,881	43,765
..... number	3,600,000	3,468,000
of slag	1,199,000	3,648,000

men were employed during 1904. In the last few years the output of bricks made from as much increased, having proved excellent for ig purposes, so much so that over 15,000,000 bricks already been used. The selling price at the works

not less than 30,000 bricks, 16 marks 50 pf. per for not less than 50,000 bricks, 16 marks per 1000; t less than 150,000 bricks, 15 marks 50 pf. per

blast furnace slag is also used in pieces, or in cast which are extremely hard, and have a high sp. dykes, quay walls and bank protections. For bricks lime is mixed with the slag in presses at a high pressure; the bricks harden in 36 to rs.

X.—METALLURGY.

MINING IN BILBAO.

For. Off. Ann. Series, No. 3352.

following is an approximate return of the different of iron ore worked in the province of Bilbao.

	1902.	1903.	1904.
	Tons.	Tons.	Tons.
.....	4,182,500	4,267,078	4,433,885
te	442,237	509,801	582,036
il	57,081	81,634	54,537
Total	4,681,818	4,858,513	5,070,458

Iron ore exported from Bilbao during the last three as follows:—1902, 4,196,851 tons; 1903, 4,028,730 1904, 3,846,352 tons. Of these totals, there was d to the United Kingdom, 1902, 2,996,908 tons; 2,649,004 tons; 1904, 2,490,352 tons. Besides ove quantity, 53,341 tons were shipped coastwise l, chiefly to Gijon, whilst of the total output of us 657,791 tons remained in stock.

remaining ores worked in the province of Biscay were as follows:—Calamine, 2,963 tons; Pyrites 1,914 tons; pyrites of copper, 270 tons; lead, blende, 55 tons.

MINING INDUSTRY OF POLAND.

For. Off. Ann. Series, No. 3351.

mpts were made last year to work the old lead pper mines in the neighbourhood of Kielce, which ploited 100 years ago, with fair results; but the ine at Karczowka, which was reported to be ily rich, only gave about 10 tons of galena for six rk. Similar attempt to work the old copper t Chenciny were also made on a small scale. The arbonate of copper, impure malachite and azurite, hich sulphate of copper is manufactured. This sul-

phate commands a better price than that prepared in the chemical factories, as it does not contain any iron salts.

In 1904 a company prospected for lead in the govern- ment of Kielce, and were eventually successful. The ore lies about 160 ft. underground, and the seam is from 2 to 6 ft. thick. The percentage of lead is estimated at 80 to 85 per cent., and the ore also contains a certain percentage of silver.

The production of zinc is steadily increasing, as in 1904 it was nearly 11,000 tons, which is 7 per cent. more than in 1903, when it had been 20 per cent. more than in the previous year. Three works are employed in this industry.

PLATINUM PRODUCTION OF RUSSIA.

Eng. and Mining J., April 27, 1905.

The production of platinum in Russia during 1904 was 5005 kilograms, which was contributed by the districts as follows:—

	Kg.
Tcherdinsk	153'3
Perni	1,105'9
South Verkhotoorsk	3,533'6
North Verkhotoorsk	206'9
South Ekaterinburg	5'3
Total	5,005'0

This total is 1000 kg. less than the output in 1903 and 1130 kg. below that of 1902.

MERCURY IN TUSCANY.

For. Off. Miscell. Series, No. 633.]

The output of mercury in Tuscany amounted to 355 tons in 1904, valued at about 80,000*l.*, and the indications are that it is likely to increase. The most important mine is that of Siele, near Castell' Azzara. Other mines have recently been opened up at Badia, San Salvatore, and at Montebruno. The mine at Cortevicchia continues to produce regularly. On a belt of land, starting at Monte Amiata and extending southwards to Capita, there are found at intervals indications of the presence of mercury; specimens of cinnabar have been found carrying 60 per cent. of mercury.

XII.—FATS, FATTY OILS, Etc.

PITCH; HARD —. U.S. CUSTOMS DECISION.

April 28, 1905.

Hard pitch containing 50 to 60 per cent. of fatty acid compounds and no paraffins, is dutiable at 20 per cent. *ad valorem* under Section 6 of the present tariff as a "manufactured article unenumerated." The claims of the importer that it was free of duty under paragraph 617 as a "crude vegetable substance," or as "tar or pitch of wood" under paragraph 678, or as "wax vegetable or mineral," were all overruled.—R. W. M.

XIII. A.—PIGMENTS, PAINTS, Etc.

PIGMENTS; IRON OXIDE —. U.S. CUSTOMS DECISION. April 28, 1905.

"Ferrubron natural purple," consisting of 85-15 per cent. of ferric oxide and 9-15 per cent. of insoluble matter, and "ferrubron steel grey," consisting of 84-87 per cent. ferric oxide and 11-16 per cent. of insoluble matter, were held to be dutiable at 30 per cent. *ad valorem*, under paragraph 58 of the present tariff, as "colours." The importers claimed that they were dutiable at 40 cents per ton, as "iron ore," under paragraph 121, but presented no evidence in support of their claim.—R. W. M.

COLOURS; DRY —. U.S. CUSTOMS DECISION.

April 26, 1905.

Colours invoiced as "feisebocker" and "grune erde" were held to be dutiable at 30 per cent. *ad valorem* as "colours," under paragraph 58 of the present tariff. The importers claim that they were dutiable at $\frac{3}{4}$ cent per lb. as "ochery earth, ground and washed," under paragraph 49 was overruled.—R. W. M.

XIII. B.—RESINS, VARNISHES, Etc.

TURPENTINE AND RESIN OUTPUT OF BILBAO.

For. Off. Ann. Series, No. 3352.

The most important resin company in Spain is registered in Bilbao under the name of "La Unión Resinera Española." They are leasing and purchasing a great many pine-tree plantations all over Spain, and they acquired some 95,100 more trees in 1904 in the inland provinces. The total number of trees worked during that year was 6,278,485, which yielded 14,722 tons of resin.

The output of the factories amounted as follows:

	Quantity.	
	1903.	1904.
	Tons.	Tons.
Turpentine	3,146	3,440
Colophony	10,825	12,000

The sales of both products in the country were less than in the preceding year, whilst exports abroad increased by 1,600 tons on each article.

XIII. C.—INDIA-RUBBER, Etc.

RUBBER EXPORTS FROM IQUITOS, PERU.

For. Off. Ann. Series, No. 3355.

In spite of the last rubber season being very short—not having commenced till July and being completely over in February—the output was larger than in 1903 and the value much higher on account of the enhanced prices in the consuming markets. The following table shows the quantities and value of rubber shipped to European ports, New York and Brazil:—

Country.	Quantity.				
	Peruvian Slab.	Peruvian Ball.	Peruvian Fine.	Weak Fine.	Scrappy Negroheads.
	Kilos.	Kilos.	Kilos.	Kilos.	Kilos.
United Kingdom	27,268	658,073	303,450	11,473	158,478
Germany	1,331	46,093	62,746	1,627	16,818
France	18,967	304,268	232,787	5,618	92,891
United States	86	8,969	38,569	—	4,590
Brazil	5,314	23,455	109,073	524	27,952
Total	52,966	1,040,858	746,625	19,242	300,729

The total of the exports of all kinds of rubber to the different countries being: The United Kingdom, 1,158,742 kilos.; Germany, 128,615 kilos.; France, 654,531 kilos.; United States, 52,214 kilos.; and Brazil, 166,318 kilos. The total value is 669,304*l.* ss.

XVI.—SUGAR, STARCH, GUM, Etc.

SUGAR PRODUCTION OF THE HAWAIIAN ISLANDS.

For. Off. Ann. Series, No. 3365.

There are 52 sugar plantations in the Hawaiian Islands, mostly belonging to joint stock companies, with outputs ranging between 350 and 35,000 short tons of sugar per annum. Although scattered over different islands, all these plantations have agencies in Honolulu. All the sugar produced is shipped to the United States.

The sugar-producing islands of the group are, in the order of their output, Hawaii, Oahu (on which Honolulu is situated), Maui and Kauai, with an acreage of 94,000 acres planted with cane for the crop of 1904, and an acreage under cultivation of some 220,000 acres altogether. For the year ended December 31, 1904, the total crop for the whole group reached 367,475 short tons, compared with 437,991 short tons in the previous year; with the excep-

tion of the crop of 1903, this is the highest that has yet been recorded.

XVII.—BREWING, WINES, SPIRITS, Etc.

ALCOHOL FOR INDUSTRIAL PURPOSES IN THE UNITED STATES.

Times, May 15, 1905.

Preparations are being made to secure such a change in the internal revenue law as will free alcohol used for commercial purposes from the heavy tax that is now levied upon it. Manufacturers who are compelled to use alcohol in their plants have for a long time been urging the necessity for legislation similar to that in force in many other countries, under which alcohol rendered unfit for use as a beverage is exempt from internal revenue taxation. In order to provide for the loss in revenue that removal of the tax from this class of alcohol might cause they have decided to accompany their proposition with free denaturalised alcohol with a provision for the imposition of a higher tax rate on all distilled spirits used solely for beverage purposes.

XX.—FINE CHEMICALS, Etc.

MUGUET POMADE: U.S. CUSTOMS DECISION.

April 22, 1905.

The Board of General Appraisers held that muguet lily of the valley pomade, not produced from the flower but by a mixture of other essential oils, is dutiable at per cent. *ad valorem* under paragraph 3 of the tariff, as a "combination of essential oils." The claim of an importer that it was free of duty as "enfleurage grease" under paragraph 626 or at 10 or 20 per cent. under Section 6 was overruled.—R. W. M.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journal in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—PLANT, APPARATUS, AND MACHINERY.

- [A.] 9108. Newell and Fennell. Rotary kilns. May
 " 9115. Bick. Centrifugal separators. [Appl.
 Sweden, May 9, 1904.]* May 1.
 " 9177. Climax Kiln Co., Ltd., and Grimwa
 Continuous muffle furnaces or kilns. May 2

- A.] 9417. Aktiebolaget Separator. Centrifugal separators for liquids. [Appl. in Sweden, May 5, 1904.]* May 4.
9572. Leunox and Dawson. *See under XVII.*
9603. Mueller. Vaporisers.* May 6.
9606. Brearley. Method of determining the temperature of heated spaces or areas. May 6.
9634. Day. Condensing plant.* May 8.
9676. Newell and Fennell. Rotary kilns and the like. May 8.
9994. Hunt (Hunt). Separation of solids from liquids. May 12.
- S.] 10,797 (1904). Van der Heyden. Solidification of fluids. May 10.
- 12,606 (1904). Proctor and Morgan. Method of heating or cooling fluids. May 10.
- 13,765 (1904). Johnson. Apparatus for separating coal, slack, ores, minerals, or substances of different specific gravity. May 10.
- 15,010 (1904). Reavell. Cooling towers for reducing the temperature of condensing water and other liquids. May 10.
- 15,088 (1904). Dixon. *See under II.*
- 24,497 (1904). Saade. Refrigerating and cooling vessels. May 17.

II.—FUEL, GAS, AND LIGHT.

- J.] 9152. Genz. Method for utilising the gases of combustion generated in kilns and furnaces. May 1.
9171. Hills. Gas producing plant. May 2.
9369. Hahn. Gas heated coking ovens. May 4.
9386. Ratcliffe. Utilisation of waste wood, shavings, sawdust, &c., as briquettes or fire lighters. May 4.
9548. Kestner. Process whereby furnace and other gases may be completely and rapidly freed from dust, &c., held in suspension therein, and apparatus therefor. May 5.
9588. Shedlock. Manufacture of coke and apparatus therefor. May 6.
9668. Schmidt. Apparatus for producing a mixture of combustion gases and steam.* May 8.
9705. Consen. Apparatus for generating hydrocarbon vapour. May 8.
9864. Hirsch. Manufacture of incandescing bodies for incandescent lighting.* May 10.
9885. Jahns. Process and apparatus for the production of producer gases. [Ger. Appl. Nov. 4, 1904.]* May 10.
9919. Wilson. Gas producers. May 11.
9948. Hermansen. Regenerators for retort and other furnaces.* May 11.
- 10,006. McIntyre. Manufacture of artificial fuel. May 12.
- 10,075. Radcliffe. *See under VII.*
- [S.] 10,066 (1904). Strong. *See under X.*
- 10,067 (1904). Strong. *See under X.*
- 11,917 (1904). Warburton. Process for obtaining producer gas and electrical energy from peat. May 17.
- 13,236 (1904). Sheldrake. Gas washer scrubbers. May 10.
- 13,517 (1904). Dunlop, and Kynoch, Ltd. Gas producing plant. May 10.
- 14,157 (1904). Armstrong. Manufacture of coke, and furnaces, ovens and apparatus therefor. May 10.
- 15,087 (1904). Dixon. Blast nozzles for gas producers. May 17.

- [C.S.] 15,088 (1904). Dixon. Gas washing, cleaning, and cooling towers. May 17.
- .. 15,821 (1904). Mason. Apparatus for manufacturing producer and water gas. May 17.
- .. 16,895 (1904). Bloxam (Bradley). Gas producers. May 10.
- .. 916 (1905). May. Process of making fuel from garbage. May 17.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 9748. Garle and Neumann. Method of rendering certain inflammable solvents non-inflammable. May 9.
- [C.S.] 19,744 (1904). Blackmore. Process for making hydrocarbons and separating sulphur from sulpho-hydrocarbons or sulphurous petroleum. May 10.
- .. 24,551 (1904). Scholvien. Process for the manufacture of benzenes and hydroxyl derivatives of the same. May 10.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 9138. Newton (Bayer und Co.). Manufacture of new anthracene dyestuffs. May 1.
- .. 9139. Newton (Bayer und Co.). Manufacture of a new tetrazo dyestuff especially suitable for the preparation of colouring matter lakes. May 1.
- .. 9325. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of a new *p*-amidophenylether sulphonic acid and of colouring matters therefrom. May 3.
- .. 9547. Johnson (Badische Anilin und Soda Fabrik). Manufacture of colouring matter of the naphthalene series.* May 5.
- .. 9604. Lepetit, Dollfus and Ganser. Production of logwood dyestuffs and extract for dyeing purposes. [Ital. Appl. June 4, 1904.]* May 6.
- .. 9883. Imray (Meister, Lucius and Brünig). Manufacture of concentrated liquid dyestuffs or easily liquifiable pastes from sulphurised dyestuffs. May 10.
- .. 10,022. Imray (Soc. Chem. Industry in Basle). Manufacture of azo dyestuffs. May 12.
- .. 10,101. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of new sulphurised dyestuffs. May 13.
- [C.S.] 10,925 (1904). Lilienfeld. Manufacture of indigo or homologues or derivatives thereof. May 17.
- .. 14,970 (1904). Imray (Meister, Lucius and Brünig). Manufacture of new dyestuffs of the anthracene series. May 10.
- .. 14,972 (1904). Imray (Meister, Lucius and Brünig). Manufacture of yellow mordant dyestuffs. May 10.
- .. 15,025 (1904). Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Manufacture of *o*-oxyazo colouring matters. May 10.
- .. 15,418 (1904). Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Manufacture of a nitro-1-diazo-2-oxy-naphthalenesulphonic acid or sulphonic acid of the nitronaphthalene-1,2-diazo-oxide. May 10.
- .. 15,624 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of 1,8-arylnaphthylaminesulphonic acids. May 17.
- .. 16,538 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of violet-blue colouring matters of the anthracene series and of intermediate products. May 17.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 9088. Fleet and Roberts. Dyeing and stripping wool, silk, and other fibres by the use of electricity. May 1.
- .. 9311. Mills and Parker. *See under XIV.*
- .. 9572. Lennox and Dawson. *See under XVII.*
- .. 9683. Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging agents. May 8.
- .. 9698. Küess. *See under XIX.*
- .. 9809. Frankenstein, Spencer, Spencer and Lyst. Calico printing. May 10.
- [C.S.] 10,272 (1904). Kellner. Process and means for washing textile fabric. May 10.
- .. 12,632 (1904). Wohle. Detergent for scouring wool. May 10.
- .. 15,943 (1904). Johnson (Badische Anilin und Soda Fabrik). Production of coloured discharges on dyed materials. May 10.
- .. 15,944 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging pastes for use in the discharging of dyed textile fabrics. May 10.
- .. 16,185 (1904). Bartelt. Apparatus for preparing bleaching liquor. May 17.
- .. 1591 (1905). Linkmeyer and Pollak. Manufacture of artificial silk from solutions of cellulose. May 10.
- .. 4761 (1905). Linkmeyer. Manufacture of lustrous threads of cellulose. May 17.
- .. 7005 (1905). Gerlach. Cylinders for steaming and shrinking cloth and the like. May 17.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

- [C.S.] 14,362 (1904). Marinier. Apparatus for applying designs or the like in atomised colours to paper or other material. May 17.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 9239. Dolphin. Apparatus for use in the manufacture of sulphate of copper and the like. May 2.
- .. 9404. Haworth and Baker. *See under XX.*
- .. 9443. Clemm. Treatment of phosphates and the production of chlorine and of citrate soluble phosphates. May 4.
- .. 9666. Oelder. Muffle furnaces and apparatus for the manufacture of sodium sulphate and concentrated hydrogen chloride. [Ger. Appl. May 9, 1904.]* May 8.
- .. 10,038. Vautin and Burt. Reducing agent for metallic oxides, chlorides and fluorides. May 12.
- .. 10,975. Radcliffe. Treatment of certain products of ammoniacal liquor obtained by washing illuminating and heating gases. May 13.
- [C.S.] 11,991 (1904). Boi-sière and Faucheux. *See under XX.*
- .. 28,613 (1904). Eyde. Production of nitrites. May 10.
- .. 28,614 (1904). Eyde. Production of pure nitrites from a mixture of nitrates and nitrites. May 10.
- .. 8816 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of stable dry hydro-sulphites. May 17.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [A.] 9211. Sievert. Manufacture of sheet glass. [Belg. Appl., April 12, 1905.]* May 2.
- [C.S.] 10,676 (1904). Bottomley, Hutton, and Paget. Manufacture of silica glass. May 17.

IX.—BUILDING MATERIALS, CLAYS, MORTAR AND CEMENTS.

- [A.] 9103. Westhoff. Process of converting waste material of paper mills into acidless, stone-like porous bodies of an easy specific weight. May 1.
- .. 9221. Thom. Manufacture of artificial marl, dolomite, &c.* May 2.
- .. 9422. Préaubert and Thubé. Product for tanning or asphalted roads, and process of manufacture same. [Fr. Appl., May 5, 1904.]* May 4.
- .. 9587. Herdman. Apparatus for use in production of slag wool. May 6.
- .. 9610. Goldschmidt. Process for producing refractory crucible lining for aluminothermic processes. May 6.
- [C.S.] 11,151 (1904). Hamblet. Brick kilns and the like. May 17.
- .. 14,860 (1904). Dean and Redfern. Kilns for drying and burning bricks, tiles, or the like. May 10.
- .. 17,870 (1904). Elmes. Manufacture of artificial stone, plaster, or plastic material. May 17.

X.—METALLURGY.

- [A.] 9199. Thiel. Manufacture of iron.* May 2.
- .. 9249. Rilely. Treatment of slag and apparatus therefor. May 2.
- .. 9447. Cowper-Coles. *See under XI.*
- .. 9877. Queneau. Manufacture of metallurgical vessels. [C.S. Appl., May 21, 1904.]* May 10.
- .. 10,036. Head. Acceleration of the manufacture of open-hearth steel or ingot iron. May 12.
- [C.S.] 9836 (1904). Lévy. Production of metallic deposits upon metal to prevent the same from oxidation. May 10.
- .. 10,066 (1904). Strong. Manufacture of blocks and briquettes for the production of steel and other metals, and for fuel. May 10.
- .. 10,067 (1904). Strong. Apparatus for manufacturing blocks and briquettes for the production of steel and other metals, and for fuel. May 10.
- .. 12,817 (1904). Brayshaw. Process of hardening high speed tool steel. May 10.
- .. 13,765 (1904). Johnson. *See under LX.*
- .. 14,214 (1904). Simpkin and Ballantine. Means for dephosphorising iron ores and concentrates. May 10.
- .. 16,276 (1904). Kaufmann and Bouvier. Manufacture of steel. May 10.
- .. 23,909 (1904). Barber (Kingsley). Apparatus and process for treating sulphide and other ores. May 10.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 9008. Fleet and Roberts. *See under V.*
- .. 9447. The Metals Corporation, Ltd., and Cowper-Coles. Electrolytic refining of copper. May 4.
- .. 9448. Cowper-Coles. The electrolytic deposition of metals. May 4.
- .. 9522. Bottomley and Paget. Electric resistance furnaces. May 5.
- .. 9543. Crowley and Macleod. Primary batteries. May 5.
- .. 9657. Gouin. Electric accumulators. [Fr. Appl., May 9, 1904.]* May 8.
- .. 9708. Cowper-Coles. Electrodeposition of iron. May 9.

9901. Richardson. Primary battery May 11.
 10,119. Dickson. Electric insulating materials. May 13.
 10,120. Schiele. Electro-plating of metals.* May 13.
 10,794 (1904). Blackmore and Byrnes. Electrolytic apparatus. May 17.
 11,288 (1904). Ricks. Electric accumulator plates or electrodes. May 17.
 11,917 (1904). Warburton. *See under II.*
 16,648 (1904). Rudge-Whitworth, Ltd., Pugh, and Heathcote. Apparatus to be used in the electro-plating of metallic articles. May 10.

FATTY OILS, FATS, WAXES, AND SOAP.

- 10,001. Harrison, Wild and Robb. Method of and means for treating offensive odours given off by fish refuse during the process of extracting oil from it, or of its manufacture into manure. May 12.
 17,965 (1904). Horn. Process for the preparation of soaps. May 10.
 3438 (1905). Haase. Manufacture of candles and the like. May 10.

PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, ETC.

(A.)—PIGMENTS; PAINTS.

9480. Herisson. Method of manufacturing oil colours. May 5.
 10,030. Jürgensen. Paint or coating composition. May 12.

(B.)—RESINS, VARNISHES.

- 27,667 (1904). Jackson. Floorcloth, waxcloth, oilcloth, linoleum, and kindred goods. May 10.
 6371 (1905). Smith. Manufacture of linoleum, floorcloths, and the like. May 17.

TANNING, LEATHER, GLUE, SIZE, ETC.

9311. Mills and Parker. Apparatus for degreasing leather, wool, and other materials of like nature. May 3.
 9394. Fontana. Process for decolourising tanning extracts. May 4.
 9779. Harger. Treatment of various substances—such as bones, skins—for obtaining useful products therefrom. May 9.
 9902. Marsden. Apparatus or digesters for treating bones to obtain valuable products therefrom. May 11.
 18,514 (1904). Amend. Process for bating and puring skins. May 17.

XV.—MANURES, ETC.

- 10,001. Harrison, Wild and Robb. *See under XII.*
 10,023. Von Haeften. Treatment of peat, particularly for making manure, and apparatus therefor. May 12.

XVI.—SUGAR, STARCH, GUM, ETC.

9137. Roy. Apparatus for the treatment of massecuite. [Fr. Appl., May 2, 1904.]* May 1.

XVII.—BREWING, WINES, SPIRITS, ETC.

- [A.] 9572. Lennox and Dawson. Evaporator for evaporating the liquid in brewers' wash or pot ale from distilleries, sewage, waste or spent dyes and the like, and concentrating the solids in the same. May 6.
 " 9639. Lugo. Process of purifying and ripening grape wines. May 8.
 " 9704. Hunt. Treatment or utilisation of fuel oils and feints. May 8.
 [C.S.] 10,320 (1904). Vignier. Apparatus for distilling whisky and brandy. May 17.
 " 11,174 (1904). Dorn. Process for the maturing of wines and spirits, and for sterilising liquids. May 17.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

- [A.] 9457. James (The Organose Co.). Manufacture of a food product.* May 4.
 " 9703. Franzén. Method of treating liquids with hydrogen peroxide or other germ killers. [Appl. in Sweden, June 23, 1904.]* May 8.
 [C.S.] 11,174 (1904). Dorn. *See under XVII.*
 " 15,440 (1904). Inray (Maragliano). Manufacture of meat powder or meal. May 17.
 " 46 (1905). Soc. Anon. "Union," and Jurgens. Process of improving margarine and the like. May 10.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 9572. Lennox and Dawson. *See under XVII.*
 " 9578. Adams. Bacterial sewage purification plant, and apparatus connected therewith. May 6.
 " 9733. Hall and Hall. Apparatus for treating gases, smoke, and other products of combustion so as to render them innocuous. May 9.
 [C.S.] 10539 (1904). Stringfellow. Treatment and utilisation of sewage and other refuse. May 10.
 " 22,724 (1904). McLean and Paterson. Treatment of sewage. May 17.
 " 2219 (1905). Hamilton. Compound for removing scale from boilers. May 17.
 " 5932 (1905). Mitchell. Inhaling compound for firemen's use. May 10.

(C.)—DISINFECTANTS.

- [A.] 9656. Griesse. *See under XX.*

XIX.—PAPER, PASTEBOARD, ETC.

- [A.] 9103. Westhoff. *See under IX.*
 " 9698. Küss. Transformation of alfa and other similar plants into paper pulp or textile fibres. [Appl. in Tunis, May 9, 1904.]* May 8.
 " 9832. Heys (General-Direction der Hugo, Lazy, Henckel von Donnersmarch-Beuthen). Process of manufacturing paper.* May 10.
 " 9998. Fabr. Prod. Chim. Flora Soc. Anon. Process for directly converting cotton or cellulose into cellulose acetates. [Fr. Appl., Aug. 23, 1904.]* May 12.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 9114. Valentiner. Manufacture of salicylic acid methylene acetate. [Ger. Appl., July 16, 1904.]* May 1.

- [A.] 9404. Haworth and Baker. Manufacture of carbon tetrachloride and sulphur chloride. May 4.
- .. 9505. Thorpe. Process for making an organic compound for physiological or other use. May 5.
- .. 9550. Chem. Fabr. auf Actien, vorm. E. Schering. Manufacture of camphor. [Ger. Appl., May 17, 1904.]* May 5.
- .. 9656. Griese. Preparation of *m*-iodo-*o*-oxyquinoline-*ana*-sulphonic acid readily soluble in the stomach, and medicaments or internal disinfectants containing the same.* May 8.
- .. 10,093. Wetter (Hoffmann La Roche & Co.). Benzoyl salicylic acid. May 13.
- [C.S.] 11,991 (1904). Boissière and Faucheux. Processes for the manufacture of potassium bitartrate and tartaric and citric acids in which torrefaction is employed. May 10.
- .. 14,955 (1904). Gärtner. Polychlorals and the manufacture of the same. May 17.
- .. 15,930 (1904). Liebreich. Preparations for the production of chloroform. May 17.
- .. 22,126 (1904). Merck, Merck, Merck and Merck. Method for the preparation of pyrimidines. May 17.
- .. 22,127 (1904). Merck, Merck, Merck and Merck. Method for the preparation of pyrimidines. May 17.
- .. 22,128 (1904). Merck, Merck, Merck and Merck. Method for the preparation of pyrimidines. May 17.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 9116. Abel (Act.-Ges. f. Anilinfabr.). Develop and finishing photographic plates, films, or like, and photographic developers for use the May 1.
- .. 9246. Sandell Films and Plates, Ltd., and Sandell. Photographic plates and films.* May 2.
- .. 9324. Abel (Act.-Ges. f. Anilinfabr.). Sensitizing layers of gelatin, gum, or the like for the pigments and like photographic processes. May 3.
- .. 9497. Mallabar. Rapid production of photographs on silver chloride paper without the use of May 5.
- .. 9537. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of a new compound of the aromatic series and a photographic developer containing this compound. May 5.
- .. 9667. Mallet. Manufacture of photographic paper. May 8.
- .. 9870. Kelly and Bentham. Treating solutions for chemicals for photographic and other uses. May 10.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [C.S.] 10,663 (1904). Bell. Method and apparatus for the formation of gun-cotton blocks. May 1.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London in July next, and the proceedings will commence on Monday, July 10th.

In accordance with the provisions of Rule 18 of the By-Laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council will retire from their respective offices at the forthcoming Annual Meeting.

Dr. Edward Divers, F.R.S., has been nominated to the office of President under Rule 8; Dr. L. Baekeland, Mr. J. Carter Bell, Dr. J. Lewkowitsch, and Mr. N. H. Martin have been nominated Vice-Presidents under Rule 8; and Mr. Wm. H. Nichols has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices.

Mr. J. Bingham Alliot, Dr. J. T. Dunn, Mr. A. R. Ling, Mr. J. S. McArthur, Dr. K. E. Markel, and Mr. Charles Procter have been nominated under Rule 18 to fill four vacancies among the Ordinary Members of Council.

A Ballot List, Member's Ticket, Supplementary Programme, and Request Form are contained in this number.

BIRMINGHAM SECTION.

The Birmingham Section of the Society, after an interval of some years, has resumed active work. The meetings will be held at the University, and Prof. Percy F. Frankland, F.R.S., has accepted the chairmanship, with Mr. F. R. O'Shaughnessy as Hon. Local Secretary and Treasurer.

NEW ENGLAND SECTION.

The New England Section held its inaugural meeting at Boston, Mass., on May 12th. Between 80 and 90 members were present, including the President of the Society, with Dr. H. Schweitzer, Mr. T. J. Parker, and other representatives of the New York Section.

CONGRESS OF CHEMISTRY AT LIÈGE.

In connection with the Liège Exhibition, a Congress of Chemistry and Pharmacy will be held from the 27th to the 30th July next. By a subscription of 10 francs, members may take part in the Congress, and will receive a copy of the transactions. Application for Adhesion Forms and programmes should be made at once to M. J. Raymond, Pharmacien, Liège, or M. J. Wanters, Chimiste-adjoint de la Ville de Bruxelles.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna 89, Rome.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

MR. A. GORDON SALAMON IN THE CHAIR.

ACTION OF HYDROGEN PEROXIDE ON A PHOTOGRAPHIC PLATE IN THE DARK.

BY CHIRI OTSUKI, PH.D.

The action of hydrogen peroxide on a photographic plate in the dark, which was studied first by Russell,⁽¹⁾ recently been considered by Graetz⁽²⁾ to be a radiation of this substance. Russell states in his paper that hydrogen peroxide acts not only directly on a photographic plate in the dark, but also through several solids. The chief reasons why Graetz considers this action of hydrogen peroxide to be a kind of radiation are, because it penetrates through several solid substances, such as paper, gelatin, celluloid, ebonite, &c., and through thin sheets of metals; secondly, because the action cannot be prevented by passing a rapid stream of air through the space between the photographic plate and the peroxide solution during the exposure.

The first part of this paper treats chiefly of the question of radiation of hydrogen peroxide; the second treats of the nature of the action of the peroxide on a photographic plate.

PART I.

(1) On the Permeability of various Substances to the Action of Hydrogen Peroxide.

(a) Preliminary experiments with gelatin, celluloid, &c.

One c.c. of a 30 volume aqueous solution of hydrogen peroxide was poured into a small vessel. A thin sheet of the substance to be examined was placed over it at the distance of 1 cm. from the surface of the peroxide solution, and then a photographic plate was laid upon it. After some time the photographic plate was developed for 60 seconds by means of 5 per cent. commercial sodinal solution. The results were as follows:—

[No.]	Substances Employed.	Thickness of Substances.	Time of Exposure.	Effect on Developed Plates.
1	gelatin	m.m.	Hours.	
2	gelatin	0.12	2	dark
3	gelatin	0.12	24	dark
4	celluloid	0.05	2	dark
5	celluloid	0.26	2	dark
6	celluloid	0.79	24	dark
7	black packing paper	0.15	2	very dark
8	soft gum	0.40	24	very dark
8*	Canada balsam	—	24	dark
9	ebonite	0.18	20	without effect
10	fish membrane	—	24	without effect
11†	paraffin	—	24	without effect
12	glass	0.75	24	without effect

* No. 8.—A thin sheet of celluloid 0.05 mm. thick was coated on both sides with Canada balsam, and when dry was used for the experiment.

† No. 11.—A sheet of celluloid 0.05 mm. thick dipped in melted paraffin and cooled was used for the experiment.

The above substances were next placed between a 30 volume aqueous solution of the peroxide and a photographic plate which had been previously perfectly fixed. After some time the gelatin layer of the fixed plate and the upper surface of the substance which had been placed between the fixed plate and the peroxide solution were examined by means of titanium reagent (titanic oxide dissolved in concentrated sulphuric acid), and also of an aqueous solution of chromic acid. With gelatin, celluloid, paper, soft gum and Canada balsam, a yellow to orange coloration by the titanium reagent, and a green coloration by the chromic acid were always noticeable, after the exposure for the same length of time as in the last experiment; with ebonite, fish membrane, paraffin, and glass no coloration was noticeable. The experiments were made at the ordinary temperature.

(b) Experiments with thin sheets of glass.

A small vessel of glass containing 1 c.c. of a 30 volume aqueous solution of hydrogen peroxide was covered with a sheet of glass 0.75 mm. thick. A photographic plate was placed upon it at a distance of 7 mm. from the surface of the peroxide solution. After an exposure for four hours, the photographic plate was developed as above.

The part of the plate which had been in contact with

FIG. 1.

the sheet of glass showed no change after development; the other parts, however, appeared quite dark, and

this darkening extended a little within the contour line of the sheet of glass. (Fig. 1.)

By increasing the time of the exposure to 24 hours

FIG. 2.

the darkening of the plate extended further inwards. (Fig. 2.)

By allowing a certain space between the sheet of glass

FIG. 3.

0.12 mm. space between the photographic and the glass plates.

and the photographic plate, instead of laying it directly upon the glass plate, the darkening extended much further toward the centre than in the latter case. (Fig. 3.)

By increasing the space between the photographic and

FIG. 4.

1.5 mm. space between the photographic and the glass plates

the glass plates the extension of the darkening toward the centre increased more and more. (Fig. 4.)

After laying a photographic plate for 42 hours on a closed vessel of thin glass containing a 30 volume aqueous solution of hydrogen peroxide, no darkening of the plate was observed when the plate was developed. The vessel was made perfectly air-tight, so that it was quite impossible for any peroxide vapour to escape.

Further, a small vessel of glass containing 30 volume hydrogen peroxide solution was loosely covered with a

FIG. 5.

second cylinder of thin glass and a photographic plate was placed upon it for 42 hours. On developing, the plate showed no darkening at the part where it had touched the cylinder; the remaining parts of the plate, however, appeared dark. (Fig. 5.)

On examining a sheet of gelatin placed upon a peroxide solution over a thin sheet of glass by means of a titanium reagent and of the chromic acid, no coloration was noticeable.

(c) Experiments with thin Sheets of Metals.

A small vessel of glass containing 1 c.c. of 30 volume aqueous solution of hydrogen peroxide was covered with a thin sheet of metal, and then a photographic plate was placed upon it.

With the thin sheets of metals—zinc 0.09 mm. thick, copper 0.05 mm. thick, tin 0.01 mm. thick, alloy of composition of $\text{Au} + \frac{1}{10} \text{Pt} + \frac{1}{10} \text{Ag}$ 0.008 mm. thick, brass 0.005 mm. thick at an exposure for $\frac{1}{2}$ —38 hours, the distance of 0.5 cm. from the surface of the peroxide solution, no effect of the peroxide was perceived either photographically or chemically.

By making parallel experiments, any mistake such as that known as Russell's effect (3) was quite out of the question.

With regard to aluminium, three degrees of thickness, 0.08 mm., 0.005 mm., and 0.003 mm., were employed for the experiments. The last is known usually at Lénard's aluminium.

It was not very easy to find a piece of Lénard's aluminium quite free from small holes; and since the peroxide vapour passes through the most minute of holes, the experiments were made with the greatest care.

A plate of glass having a small hole of 1 mm. diameter was cemented to a thin sheet of aluminium by means of paraffin. The aluminium foil was examined before and after cementing it on to the glass plate under a microscope to ascertain if it was free from holes. The plate was laid upon a small glass vessel containing 30 volume aqueous solution of hydrogen peroxide, and was fastened to the vessel by means of paraffin. The distance between the foil and the surface of the peroxide solution was 5 mm. Then a photographic plate was placed upon it. After an exposure for from a half to three hours, the photographic plate was developed in the usual way. The aluminium foil was again examined after the exposure under a microscope. In experiments with Lénard's aluminium could not be made at an exposure over three hours, for the sheet would be corroded by the peroxide vapour, as Graetz (4) has already observed.

In 47 experiments an effect on the photographic plate was observed only three times, but in all the three cases, small holes were discovered in the foil owing to corrosion of the metal by the peroxide vapour. With foil 0.08 mm. thick, no effect on a photographic plate was obtained even after an exposure of 38 hours.

Graetz employed Canada balsam (5) as the cementing material in his experiments, but since this is permeable to the peroxide it cannot be said that the action penetrates through aluminium.

The Action of Hydrogen Peroxide on a Photographic Plate by Exposing a Second Plate to the Peroxide and Pressing them together for some time.

We have already seen that when sheets of such substances as gelatin, celluloid, &c., are exposed to the oxide solution, then the chemical examinations show the presence of hydrogen peroxide on the surface of these substances.

Accordingly, if a plate with a sheet of such substance placed above be exposed to the peroxide solution, and then pressed against a photographic plate, the latter should become capable of being developed. The following experiments confirm this: a 4 per cent. solution of collodion was poured over a clean plate of glass, and after completely drying, it was exposed to a 3 volume aqueous solution of hydrogen peroxide at the distance of 1 cm. from the surface of the liquid. Then the plate was pressed closely to a photographic plate in a copying machine for 30 minutes in the dark. On developing this photographic plate in the usual manner, a distinct darkening was obtained. On using gelatin instead of collodion the same results were obtained. When the second plate was heated after it had been exposed to the peroxide solution no darkening of the photographic plate was obtained.

On the chemical examination with the titanium reagent carried on in the following manner: A collodion plate prepared as in the last experiment was exposed to an aqueous solution of hydrogen peroxide. Then it was pressed closely to a fixed photographic plate in a copying machine for some time. By examining these plates with the titanium reagent a yellow coloration was noticeable. On the collodion plate, however, was heated, after it had been exposed to the peroxide solution, and pressed against a fixed photographic plate neither plate gave coloration with the titanium reagent. On using gelatin instead of collodion the same results were obtained. It must therefore be concluded that the peroxide vapor condensed on the plate which was exposed to the oxide solution is removed when the plate is heated after the exposure.

The photographic copying process, which is called by Katatype by evaporation," is based on this change. An ordinary photographic negative is exposed to an aqueous solution of the peroxide and then in the dark it is pressed closely against a photographic plate in a copying machine for some time. At the dark parts of the negative the condensed hydrogen peroxide is decomposed catalytically through metallic silver to water and oxygen, while absorbed by the gelatin layer at the clear parts of the negative without the decomposition. Thus a latent image of hydrogen peroxide is produced in the negative. When pressed closely against a photographic plate for some time, this latent image of the peroxide is transferred to the plate, and a positive image is obtained by developing. When the exposed negative is pressed against an ordinary gelatinised paper, instead of a photographic plate, the latent image of the peroxide is transferred on to the paper. By treating the paper with a solution of an easily oxidisable metallic salt the latter is oxidised by the peroxide, and a positive image consisting of the oxidised salt is produced on the paper. For example, by treating the paper with a solution of ferrous sulphate a faintly coloured image consisting of ferric salt is produced on the paper. By treating this with a solution of pyrogallie acid a blackened positive image is obtained.

This process is similar to that of Gros's Katatype (6) except that it is operated by the evaporation of hydrogen peroxide solution, it is called by us "Katatype by evaporation."

From the experiments described above, it is concluded that the effect on a photographic plate in the dark by hydrogen peroxide cannot be considered as caused by radiation from the peroxide.

(3) *Experiments with a rapid Current of Air.*

One of the reasons why Graetz maintains the action of the peroxide to be due to a kind of radiation, is that the effect cannot be dispelled by blowing a rapid current of air

into the space between the photographic plate and the peroxide solution during the exposure.

In order to study the fact the following experiments were made:—

A photographic plate was laid upon a glass plate having a small hole (3 mm. diameter) in its centre, and the plate was kept quite cold(?) during the experiment by laying on it a large copper cylinder containing ice water. The muzzle of the blowing pipe was placed directly under the hole, the diameter of the muzzle being much larger than that of the hole and of the vessel containing the peroxide solution. During the blowing of a rapid current of air a small vessel containing 30 volume aqueous solution of the peroxide was brought under the hole, keeping the distance of 0.8 cm. between the sensitive layer of the photographic plate and the surface of the liquid. After the exposure the photographic plate was developed in the usual way. It was found that a distinct picture of the hole was obtained on development; but that part of the sensitive layer corresponding to the hole was moist in every experiment. This moistening was, however, unavoidable, because it was not possible to attempt to dry thoroughly such a large amount of air as was necessary for this experiment. By laying the photographic plate 11 minutes in water after the exposure, the degree of darkening of the picture of the hole decreased. By developing the plate after leaving it one hour in water after the exposure no picture of the hole was obtained.

Since the effect of the hydrogen peroxide can be eliminated by laying it for some time in water it cannot be considered as caused by a radiation; neither can it be assumed that the moisture which condenses on the photographic plate causes the effect. There must be some trace of the peroxide in the condensed moisture to cause the change, because by moistening the sensitive layer of an exposed plate with a drop of distilled water and blotting it, this part of the plate appeared lighter than the remaining parts after the development.

PART II.

(4) *Influence of Temperature.*

The influence of temperature on the photographic action of hydrogen peroxide is very interesting. A small difference in temperature in the photographic plate or between the plate and its surroundings, causes lighter or darker zones in the picture, either the border being lighter than the centre or *vice versa*. This phenomenon was called by Graetz a "border effect" (Randwirkung)(8). He considers that that part of the plate where a current of heat enters is darkened more than that where it goes out, and he assumes that this is due to the falling of the temperature. According to Schaum and Braun,(9) however, the photographic effect of hydrogen peroxide is almost nullified at 0° C., and increases to a certain maximum and then decreases suddenly with an increase in temperature.

Our experiments show that when the temperature of the vessel containing the peroxide solution is equal to that of the sensitive layer of the plate, then the plate shows a uniform darkening over the whole surface of the picture. When the photographic plate is heated to a very high temperature—which is effected by placing a large vessel containing boiling water on the glass side of the plate during the exposure—no darkening of the plate takes place, though the sensibility of the plate does not decrease. By decreasing the temperature of the plate without changing any other conditions, the photographic action of the peroxide increases gradually, but this does not happen without a limit, so that the plate shows less darkening at 0° C. than at the ordinary temperature.

This phenomenon of the picture appearing lighter or darker depends on two factors, one of which is the degree of condensation of the peroxide on the plate, the other the influence of temperature upon the reaction between the hydrogen peroxide and the bromide of silver contained in the sensitive layer of the plate.

So far as the condensation is concerned, the effect must become greater when the temperature of the plate decreases, while the chemical reaction itself is weaker at the lower temperature.

It is important to allow some interval of time to elapse before developing, so that the temperature of the plate becomes uniform in all its parts, for the reducing power of the developer depends greatly upon the temperature.

When the sensitive plate is placed directly on the vessel containing the peroxide solution, the greatest condensation takes place at that part of the plate corresponding to the border of the vessel. On exposing the plate for a long time to the peroxide solution the border of the exposed part of the sensitive layer becomes corroded first.

A strong border effect on the exposed surface of the plate is due chiefly to temperature differences. For example, either by laying a photographic plate at the temperature of 0° C. directly upon a vessel containing a peroxide solution at an ordinary temperature, or by placing a photographic plate at the ordinary temperature directly upon a vessel containing a warm solution of the peroxide, the border of the exposed surface is darkened more than the centre. When a plate is exposed over a warm solution for a long time, it is observed that the gelatin layer of the plate is dissolved at the border of the exposed surface after the development, while its centre remains undissolved.

This fact can be explained as follows: owing to the conduction of heat to the border of the vessel, this part of the exposed surface has a higher temperature than the centre, so that the chemical action is more powerful at the border than at the centre.

When a metal cylinder, having a temperature a little higher or lower than that of the photographic plate is placed on the plate during the exposure, the so-called border-effect of Graetz is obtained. In the former case the border appears lighter than the centre, and in the latter, darker.

As already mentioned, Graetz considers this phenomenon to be due to a polar thermal effect of the falling of the temperature, but not to the difference of temperature itself.

We have found in our experiments that this phenomenon appears only with small differences in temperature, such as, for instance, when the temperature of the plate is 20° C., and that of the cylinder is 19° C. or 21° C. By placing a metallic cylinder containing boiling water on a photographic plate during the exposure, the part of the plate corresponding to the bottom of the cylinder shows no darkening, but on the surrounding parts a darkening is to be seen, so that there is no border effect. This fact may be explained as follows:—The temperature of the sensitive layer of the photographic plate is so high that no condensation of the peroxide can take place; on the surrounding parts, however, where the temperature is somewhat lower, the peroxide condenses and the chemical reaction between the peroxide and bromide of silver takes place.

Similar experiments prove that the border effect depends upon the distribution of the temperature within the glass plate.

Even though the temperature of the glass surface under the metal cylinder is uniform, yet on the lower side of the plate upon which the sensitive layer is the border zone is colder or warmer than the centre according as the metal cylinder is warmer or colder than the plate, because a heat current arises within the glass plate until it reaches a stationary condition.

By placing a metal cylinder having a flat bottom and containing a freezing mixture on the glass side of a photographic plate during the exposure the picture appears lighter at the centre than at the border. When cooling the plate only at a point—for instance by placing a semi-spherical nickel basin containing a freezing mixture upon the glass side of the plate instead of using a metal cylinder—the picture shows no lighter centre, but on the contrary, the greatest darkening is to be seen at the centre extending in all directions toward the outside, decreasing gradually in its darkness. By filling the nickel basin with boiling water instead of with freezing mixture, the darkening of the plate is reversed, so that its centre appears lighter than the surrounding parts, the darkening increasing gradually toward the outside.

In these experiments it is very necessary to isolate the apparatus from the surroundings by means of a bad

conductor of heat, for even a very small inequality of temperature causes secondary effects, from which mistake might easily arise, as pointed out by Graetz.

In order to obtain a definite effect on the photographic plate we, therefore, isolated the plate and also the nickel basin on sharply pointed corks and worked in a room of constant temperature.

If the assumption that the distribution of heat with the glass of the photographic plate causes this border effect to be true, then the effect should disappear when only thin sheet of sensitive layer be used instead of the glass plate; because if the photographic sheet be very thin the temperature on both the upper and lower sides should be the same. This was proved by the following experiment. By laying a copper crucible having a flat bottom and containing a freezing mixture on an ordinary photographic plate, and on a very thin sensitive film respectively, the border of the picture was darker than the centre in the first case, but in the second case, the part of the plate corresponding to the bottom of the crucible appeared uniform dark, and the surrounding part where the temperature was somewhat higher showed an intense darkening owing to the combined effect of the degree of the condensation and of the increased chemical effect.

Accordingly we believe that the border effect, which caused by a relatively small difference in temperature must certainly be due to the influence of the temperature on the chemical reaction between hydrogen peroxide and the silver bromide; for instance, under the cold cylinder the border is somewhat warmer than the centre, so that the chemical reaction is stronger at the border than the centre, and therefore the border appears dark. Under a warm cylinder the border is somewhat colder than the centre, and therefore the border appears lighter than the centre.

If one takes only the condensation into account, then the effect must be the reverse. Therefore the influence of temperature on the chemical reaction between hydrogen peroxide and bromide of silver must be the inverse of that upon the condensation.

(5) Influence of the Concentration of the Peroxide Solution on its Photographic Action.

The degree of concentration of the peroxide solution has also a very interesting influence on its photographic action. The following experiment shows this: Photographic plates were exposed for a certain length of time to aqueous solutions of hydrogen peroxide of several strengths at the distance of 1 cm. from the surface of the liquid at an ordinary temperature under the ordinary pressure; then they were developed for one minute by means of 5 per cent. commercial rodinal solution. The degrees of darkening of the produced pictures were determined by means of the Marten's polarisation photometer and calculated according to the formula⁽¹⁰⁾:—

$$Dr = 2 (\log \tan \alpha - \log \tan S),$$

where Dr is the relative density of the picture; α , the angle of rotation of Nicols for the part of the plate the density of which is to be measured, when both circles of the photometer field appear equally light; S, the angle of rotation of Nicols for the unexposed part of the plate, which was, however, developed.

The following table shows the results:—

TABLE I.

C	Log C.	Exposure 1200 sec. Dr.	Exposure 420 sec. Dr.	Exposure 140 sec. Dr.
30.0	1.477	0.696	0.289	0.087
10.0	1.000	1.145	0.407	0.053
3.0	0.477	1.245	0.360	0.030
1.0	0.000	0.996	0.176	0
0.3	— 1.477	0.741	0.066	—
0.1	— 1.000	0.353	0	—
0.03	— 2.477	0.137	—	—
0.01	— 2.000	0.060	—	—

C=volume strength of H_2O_2 in the solution.
Dr=relative density of the picture.

The following graphical Table (Table II.) is constructed on the Table I. in such a way that the ordinates present the relative density of the negative, and the abscissae, the logarithms of the concentration of the oxidizing solution:—

(v.) On developing the plate for one minute by means of 5 per cent. sodinal solution, the 3 volume solution causes a greater effect at the exposure for 20 minutes than the 30 volume solution.

These facts can be explained by the law of evaporation

TABLE II

It shows that:—

- i.) The relative density of the negative for the same exposure increases to a certain point according with increase in the strength of the solution until it reaches the maximum and then decreases.
- ii.) At the shorter exposure the relative density of the negative is smaller than that at the longer.
- iii.) The differential quotient $\frac{d Dr}{d \log C}$ (where Dr means relative density, and C the percentage of H_2O_2 in the solution) becomes less at a shorter exposure than at a longer.
- iv.) The maximum moves at the shorter exposure and the higher concentration.

and of vapour pressure of a mixture of two liquids which have been investigated by Konowalow. The vapour pressure of the 30 volume solution is less than that of water and also than that of the weaker solution. From the weaker solution the mixture of hydrogen peroxide and water evaporated per unit of time is greater in quantity than from the stronger solution. The degree of the photographic effect, however, depends not on the total amount of the evaporation, but varies with the absolute quantity of hydrogen peroxide condensed on the sensitive layer of a photographic plate. The absolute quantity of hydrogen peroxide which evaporates from the solution increases to a certain point according to the increase of the strength of the solution, when the time of exposure remains constant. In our experiment given above this maximum is observed with the 3 volume solution for the exposure of 20 minutes.

TABLE III.

(6) *Influence of Length of Time of Exposure on the Degree of Darkening of a Photographic Plate.*

As already mentioned, the relative density of the picture produced by hydrogen peroxide varies with the time of exposure. The following experiment shows the details of this variation:—

Small glass vessels containing each 1 c.c. of hydrogen peroxide solution were covered with photographic plates (¹²), at a distance of 1 cm. from the surface of the solution. After the exposure for several intervals of time the plates were developed by means of ferrous oxalate developer (¹³) and 10 per cent. commercial edinol respectively.

The relative density was determined by the Marten's polarisation photometer as above. The experiments were made at 18° C. under the ordinary pressure.

The results are shown graphically in Table III. The ordinates represent the relative densities of the negative, and the abscissæ, the logarithms of the time of exposure in seconds.

It shows that:

(i.) In the case of edinol developer the relative density of the picture increases to a certain point according to the increase in the length of the time of exposure, and reaches its first maximum, then decreases to the first minimum; then it increases to its second maximum, and sinks again to the second minimum; it next increases gradually to the third maximum, from which point it begins again to fall to the third minimum; it rises again to the fourth—the absolute maximum which seems to be the beginning of reversal. From this point the relative density decreases gradually until the picture becomes quite transparent. This reversing of the darkening of the picture resembles the phenomenon of "solarisation."

This reversal of the image has been observed by Russell (¹⁴).

(ii.) With the 30 volume solution of the peroxide the relative density of the picture is less than that with the 3 volume solution at the beginning, but it gradually approaches that of the latter until the same density is reached. From this point it goes beyond that with the 3 volume solution, so that the absolute maximum in the former case lies higher than that with the latter. The decrease of the relative density from the absolute maximum in the case of 30 volume solution is much greater than that of the 3 volume solution, so that it reaches transparency more quickly than in the latter case.

(iii.) When the plates are developed with ferrous oxalate the relative density of the picture also increases to a certain point according to the increase in time of the exposure, and reaches the first maximum, then decreases to the first minimum, from which point it suddenly increases, and goes up to the second—the absolute maximum and then suddenly decreases.

It is very remarkable that the plates which were developed with edinol show a maximum density at the points where they show a minimum in the case of iron developer, and conversely: where the relative density is in ascending stage in the case of iron developer, it is in descending stage in the case of edinol, and conversely. This fact cannot be clearly explained, but may be due to the entirely opposite character of the two developers relatively to the hydrogen peroxide as will be described afterwards.

(7) *Acid-, and Alkali-Developers.*

After exposing photographic plates for ten minutes to the 3 volume aqueous solution of hydrogen peroxide at the distance of 1 cm. from the surface of the liquid, some of them were developed for two minutes by means of ferrous oxalate developer of the composition already mentioned; some of them were developed for one minute by means of 5 per cent. commercial rodinal; others were developed only with caustic alkali solution. It was found that in the first two cases the plates became dark on developing, but in the last case, no darkening was observed until the gelatine layer was dissolved by the alkali solution. When developing unexposed photographic

plates by means of acid- or alkali-developers, or with caustic alkali respectively with the addition of hydrogen peroxide it was found that in the first case, practically no darkening of the plate was obtained; in the second case, the plate appeared dark, showing a rather yellowish tint, but the degree of darkening became much less than when it was developed only with alkali developer without the addition of the peroxide; in the third case, a darkening of the plate was also noticeable. From this experiment it follows that: (i.) The acid developer loses its developing power in a great degree when it is mixed with hydrogen peroxide.

(ii.) The developing power of an alkali developer decreases in some degree when it is mixed with hydrogen peroxide, but this decrease in the developing power is not so great as in that of an acid developer.

(iii.) Hydrogen peroxide together with caustic alkali acts as a weak developer on a photographic plate. This fact has already been mentioned by Andresen.

In the case of acid developer, as the acid which is contained in it together with the peroxide has no capacity of developing a photographic plate, the decrease in the developing power caused by the addition of a quantity of the peroxide is due only to the oxidation of the developer by the peroxide; but in the case of alkali developer, as the alkali which is contained in it gains some capacity of developing when it is mixed with the peroxide, the decrease in the developing power in this case is equal to the difference between the decrease due to the oxidation of the developer by the peroxide, and the developing power of the alkali produced by the addition of the peroxide.

(9) *Influence of the Length of the Time of Development on the Darkening of the Plate exposed to the Peroxide Solution.*

It has already been stated that the degree of darkening of the picture produced by hydrogen peroxide is greater in the case of the 3 volume solution than in that of the 30 volume solution at an exposure not longer than eight hours (compare the Table III.), when the exposed plates are developed for one minute by 5 per cent. commercial rodinal.

This result, however, is quite reversed when the exposed plate is developed for a long time. The following experiments prove this:—

Ordinary photographic plates (Lomberg extra rapid) were exposed for the same length of time to the 3 volume and 30 volume peroxide solutions respectively, and then developed for various lengths of time.

The results show that a greater degree of darkening occurs with a 3 volume than with a 30 volume solution when the plate is exposed for 1–5 minutes and developed for a short time; by increasing the time of development the density of the negative in both cases becomes about the same; by further increasing the time of development, for example, to 4–5 minutes—the density of the negative is reversed, that due to the 30 volume solution being greater.

(10) *Auto-plates and the Action of Hydrogen Peroxide.*

The action of hydrogen peroxide on auto-plates, i.e. photographic plates containing developers, is very interesting. Auto-plates were prepared for this experiment in the following manner:—

(i.) *Metol bath for Auto-plate.*

Metol (powder)	1 gm.
Sodium bisulphite	4 grms.
Water (make up to)	100 c.c.

(ii.) *Edinol bath for Auto-plate.*

Edinol (powder)	1 gm.
Acetone sulphite	6 grms.
Water (make up to)	400 c.c.

Ordinary dry plates (Lomberg extra rapid) were exposed for five minutes in the auto-plate bath, and then were dried by means of a ventilator in the dark. The plates are referred to as "metol auto-plate" and "edinol auto-plate" respectively.

The auto-plates thus prepared were placed on glass vessels containing each 1 c.c. of 30 volume aqueous

tion of hydrogen peroxide at the distance of 1 cm. from the surface of the solution. After exposure for 10 minutes they were developed for one and five minutes by means of 10 per cent. sodium carbonate solution. The exposure varied from 3.5 minutes to 10 minutes.

With the metal auto-plates, the exposed part appeared much lighter than the unexposed parts; but with the edinol auto-plates the exposed part appeared darker than the unexposed part of the plate.

This fact can be explained in the following way:—The rate of chemical reaction between hydrogen peroxide and silver is greater than that of hydrogen peroxide and silver iodide, so that at the exposed part of the plate the metal iodide is contained in the sensitive layer is first oxidised to hydrogen peroxide. Accordingly, a very small quantity of metal remains unchanged on that part of the plate.

Further, the greater part of the hydrogen peroxide condensed with the aqueous vapour from the solution is consumed for the oxidation of metal, so that bromide of silver is very slightly affected by the peroxide; therefore this part of the plate appears lighter than the unexposed part on development. In the case of edinol, however, there is no great difference in the rate of chemical reaction between hydrogen peroxide and edinol, and hydrogen peroxide and bromide of silver, so that on the exposed part of the plate bromide of silver is affected in some degree by hydrogen peroxide, and edinol remains to produce any darkening of the plate.

Action of Hydrogen Peroxide on the Latent Image Produced by Ordinary Light.

It is very remarkable that when a photographic plate is exposed to light is placed on a vessel containing hydrogen peroxide solution, that part of the plate which is subjected to the peroxide vapour appears lighter than the remaining parts when developed. This can most likely be considered as a similar phenomenon to sensitisation.

Action of Hydrogen Peroxide on Bromide of Silver.

Treating pure bromide of silver with hydrogen peroxide solution, hydrogen peroxide and caustic alkalis, or hydrogen peroxide and citric acid solutions actively, and examining the effects, the following results were obtained:—

By shaking silver bromide with 10 volume aqueous solution of hydrogen peroxide for a half to two hours in a test tube and filtering it, no bromine was found in the filtrate. Treating the residue with nitric acid and filtering it, no bromine was found in the filtrate.

(i) When pouring a mixture of 10 per cent. aqueous solution of hydrogen peroxide and caustic alkali on silver bromide, the yellow bromide turned dark immediately. After filtering, a large quantity of bromine and silver was found in the filtrate and in the residue actively.

(ii) When treating silver bromide with hydrogen peroxide and citric acid solutions and then filtering it, neither bromine nor metallic silver was found in the filtrate or the residue.

From this it is seen that by treating silver bromide free from binding material with hydrogen peroxide or with hydrogen peroxide and citric acid no decomposition of silver bromide takes place; but by treating it with a mixture of the peroxide and caustic alkali, it is decomposed to a certain extent into bromine and metallic silver.

Bromination of the Photographic Plate exposed to the Hydrogen Peroxide.

Lüppo-Cramer⁽¹⁵⁾ considers the effect produced by the peroxide not to be due to any change in the silver bromide in the sensitive film of the plate. But his conclusion cannot be confirmed according to the following experiments:—

Ordinary gelatino-bromide plates were exposed for 10 minutes to 30 volume aqueous solution of hydrogen peroxide. One of them was developed for one minute by means of 5 per cent. commercial rodinal immediately

after the exposure; the others were kept for 30 seconds in concentrated bromine water before development, then after thoroughly washing they were developed as above. In the first case the plate became dark, but in the second case no darkening was noticeable.

2. Plates were similarly exposed and then placed over a vessel containing concentrated bromine water for two hours, at a distance of 1 cm. from the surface of the bromine water. After thoroughly washing they were developed for two minutes by means of 5 per cent. commercial rodinal. There was no darkening of the plate to be seen.

3. Instead of subjecting the plates to the bromine vapour as in the last experiment, they were put into 5 per cent. bromine water for two minutes after the exposure. After washing, they were developed as in the latter case. It was found that there was no darkening of the plate.

4. The same kind of plate as used in the above experiments was kept for one minute in 3 volume aqueous solution of the peroxide. After washing it, it was laid for one minute in 5 per cent. bromine water. After again washing, it was developed as in the latter case, and a darkening of the plate was observed. Instead of placing the plate in dilute bromine water, as in the last case, it was placed in concentrated bromine water for the same length of time. It was found that after completely washing it no darkening took place on development.

It must, therefore, be concluded that the latent image produced on a photographic plate by hydrogen peroxide can be destroyed by bromination of the exposed plate after the exposure. It may be supposed that in the experiment from which Lüppo-Cramer drew his conclusion, the bromine water was not strong enough to destroy the latent image in the time applied.

(14) Hypothesis as to the Chemical Reaction between Hydrogen Peroxide and Bromide of Silver.

The chemical reaction which takes place between hydrogen peroxide and bromide of silver in the sensitive plate may be considered as follows:—

(i.) Silver bromide is oxidised by peroxide and oxybromide of silver is formed:

This oxybromide of silver, which is mentioned by Hodgkinson⁽¹⁶⁾, has probably the constitution of $2\text{AgBr} \cdot \text{Ag}_2\text{O}$.

(ii.) When H_2O_2 comes into contact with the oxybromide of silver the former decomposes to H_2O and O ; and this active oxygen combines with that of the latter, forming O_2 , as is generally the case⁽¹⁷⁾ in reductions by hydrogen peroxide. So that the chemical process goes on as follows:—

Thus the end product of the change is the subbromide of silver Ag_2Br .

In the bromination of the exposed plate the chemical reaction is:—

so that the latent image is destroyed by the bromination.

(15) CONCLUSION.

(i.) So far as the propagation in a straight line and penetration through metals are considered as the reasons of a radiation, the action of hydrogen peroxide on a photographic plate cannot be considered as a radiation of this substance.

(ii.) Gelatin, celluloid, paper, soft gums, Canada balsam allow the action of hydrogen peroxide to pass through; ebonite, glass, metals, paraffin, fish membrane do not. This conclusion coincides with that of Russell.

(iii.) The reaction between hydrogen peroxide and silver bromide gelatin depends upon the temperature. This great sensibility to temperature causes the phenomenon called "border effect." When the temperatures of the peroxide solution and of the silver bromide gelatin layer are constant and equal the border effect does not take place.

(iv.) With the same degree of concentration of the

peroxide solution the photographic effect increases according to the increase of the time of exposure. Beyond the maximum, a phenomenon similar to solarisation takes place.

(iv.) The effect of hydrogen peroxide on a photographic plate is due to the change in the bromide of silver contained in the sensitive layer of the plate. Silver bromide under the action of the peroxide changes most probably to a lower bromide of silver, which is easily reduced by the developer. The latent image produced by hydrogen peroxide consists of this lower bromide of silver, and can be destroyed by bromination.

I desire to express my thanks to Prof. Precht for his kindness in placing his laboratory at my disposal for carrying out this investigation.

DISCUSSION.

Dr. DIVERS said they were likely to get a better knowledge of the nature of photo-chemical changes by comparing them with similar changes produced in the dark by such a substance as hydrogen peroxide, than they would be if they confined their attention to those caused by light.

Mr. A. PRINGLE said neither the nature of the sensitive salts nor the ultimate action of light on the haloid salts was yet properly understood. Dr. Divers had said, very truly, that when they began to investigate, not the action of light so much, as the action of other matters apart from light, then possibly they would get nearer to an elucidation of what was really the action of light. At any rate it seemed a hopeful line to pursue. Photographers, he was sorry to say, perhaps on account of the fact that they got tangible practical results, were too little apt to investigate fundamental principles.

Rev. C. F. LAMBERT said the author's investigation appeared to explain several of the troubles which were experienced with films, and supported the well-known fact that the keeping of photographic plates was a complex matter. In his experience he found that plates kept well when packed in paper saturated with paraffin.

Mr. DAVIS said he had followed the question of the action of hydrogen peroxide on a photographic plate with some interest since Graetz's first results were obtained. Prof. Otsuki's work was first published in conjunction with Prof. Precht, and Graetz had since replied in a recent paper to several objections urged against his view that the reaction of the hydrogen peroxide was really due to a special radiation. Prof. Otsuki in the present paper had not, he thought, replied to those objections in a sufficient manner. His principal basis for considering

it the effect of a radiation was the comparative lack of volatility of the hydrogen peroxide solution. It is difficult to conceive how such a comparatively non-volatile substance could give off vapour capable of penetrating such substances as celluloid and gelatine.

It must be recognised that it had a vapour tension considerably less than water itself, and that a hydrogen peroxide solution was so comparatively non-volatile that it could be concentrated by blowing through it—a 3 volume solution could be concentrated up to 30 volumes in that way. Hydrogen peroxide was found, it is true, on the part of photographic plate which was attacked, but whether hydrogen peroxide directly permeated the gelatinous celluloid was another question. Graetz maintained that the hydrogen peroxide was formed on the plate as a secondary reaction brought about by the radiation, it seemed to him that there was considerable evidence in favour of that view. Take, for instance, the question of the permeation of hydrogen peroxide through metal plates. Even considering that there were minute pores present in the plates through which the vapour could pass, it must be acknowledged that hydrogen peroxide is so susceptible of a catalytic decomposition by metals that it was difficult to conceive that it could pass as such directly from a solution through a metal plate. There were several other objections to the view that there was such a direct passage through the various materials, but he need only refer to the latest paper of Graetz, which was published about five weeks ago. If Prof. Otsuki read that paper he should like to know what reply could be given to Graetz's objections.

Mr. S. E. SHEPPARD said that one answer to Mr. DIVERS' criticism was that the author had shown the presence of hydrogen peroxide by the "titanium" reaction, in cases where a photographic effect was obtained. Further, in a paper subsequent to Graetz's last one, Merz, in the last number of the "Ann. der Physik," showed that a photo film detached from its glass or celluloid support and exposed to hydrogen peroxide showed no action, while if exposed on a support the darkening or development started on the side of the support—just as in plates exposed through the glass. This showed that probably the condensation of the hydrogen peroxide vapour played an important part. With regard to metal screens, control experiments appeared necessary, as metal plates themselves had a photographic action, the cause of which was still uncertain.

Mr. ARTHUR MARSHALL said he understood the author to say that he considered the small effect obtained with strong solutions of peroxide as compared with weaker ones, was probably due to the fact that the vapour tension rose to a maximum. He thought that was due to a slight misapprehension. The vapour tension of a mixture might rise to a maximum, but the partial tension of one constituent could never rise to a maximum, it must increase continuously as its proportion increased. He thought the diminution was rather to be ascribed to the fact that hydrogen peroxide could act either as a reducing or as an oxidising agent.

Mr. J. THORNE BAKER said he should like to ask a question which might throw some light on the question whether the action of hydrogen peroxide was due to radiation, namely, whether the majority of the plates were of the rapid or slow variety. In rapid plates the gelatin was so treated that it became a very much more readily absorbent of bromine than the gelatine which was used in the slow plate. As bromine was liberated, according to Prof. Otsuki, possibly the gelatine in the rapid might assist the action; this would rather tend to support the view that it was not due to radiation.

Dr. RUDOLF LESSING asked if the author thought it possible to use, instead of a solution of hydrogen peroxide, one of the solid molecular compounds of hydrogen peroxide with inorganic salts such as sodium carbonate or sulphate. Under reduced pressure, these gases contain almost the whole of the hydrogen peroxide, which, when they contain, as hydrogen peroxide of crystallisation:

ld be possible to work in an atmosphere of hydrogen oxide, thus ensuring the chemical action on the plate, perhaps excluding the influence of radiation.

rof. OTSUKI, in reply, said the chief reason Graetz tioned in support of his views, that the action was to radiation, was the penetration through the gelatine other substances, and especially through metals. He lained the penetration by suggesting that there medium through which the action could penetrate. he case of celluloid, the camphor contained in it and he case of gelatine, the moisture, are the medium ough which the action could penetrate. This result already been investigated by Russell, and was recorded he proceedings of the Royal Society No. 64, 1899. a regard to the penetration through thin sheets of ls, as he understood, Graetz had experimented about aded times, and had obtained positive results in ases, and negative results in 95; but then he would t out that Graetz had used Canada balsam, and ada balsam was itself eapable of allowing the action ss through. As the whole of the glass plates which used in the experiments were very small, and the d plate which covered the glass plate was also very l, it was probable that the hydrogen peroxide found ay between the glass and the thin sheet of metal, also between the cementing materials, so that caused ction. With regard to the question of weak solutions e capable of concentration by blowing a stream of e thought that it could not be considered as a proof ydrogen peroxide did not come off from the solution. ored a small hole in a thin tinfoil about 3 mm. in eter, and a photographic plate was covered with it. On otographic plate a large cylinder with ice water was about 10 cm. distant from the hole in the foil in the site direction of the current, a small vessel containing ydrogen peroxide was placed, and a rapid stream of low through. After five minutes the plate was oped and a strong darkening was obtained; then ough the plate further distant (1 m.) from the le of the blowing pipe in the opposite direction of errent of air. The blowing was continued for about minutes, the photographic plate was then developed arkening was again obtained. After that a photoic plate was covered also with thin tinfoil having e and placed in a corner of the dark room. He this plate about ten minutes without bringing resh hydrogen peroxide near it. Of course, ydrogen peroxide remained in the vessel. He oped the plate and again obtained a strong darkening. erefore concluded that in this interval of time the gen peroxide which was blown out from the solution l with the moisture in the air, and the atmosphere dark room contained a certain quantity of hydrogen ide which condensed on the plate and produced rkening. Graetz had always used in his experiments oling plate. Now if the plate was not cold there o action; therefore, he thought it was due to the nsation of hydrogen peroxide which came off from lution. With regard to the question whether any peroxide could be used to produce this action he not say for certain, but he thought it very probable se many metals and many organic matters cong resins and terpenes and such organic bodies, which sily oxidised in the air, produced this action on the graphic plate. This was investigated by Professor er, who stated that hydrogen peroxide was always ced in the case of auto-oxidation. Therefore, e hydrogen peroxide is produced when solid per come in contact with weak acid, for instance, nic acid and moisture in the air, this effect on the graphic plates must be produced.

MR. A. GORDON SALAMON IN THE CHAIR.

INFLUENCE OF THE LENGTH OF THE TIME OF DEVELOPMENT ON THE DEGREE OF DARKENING OF THE PHOTOGRAPHIC PLATE.

BY CHIRI OTSUKI, PH.D. (TOKIO, JAPAN).

Although the density of a photographic plate depends upon the time of exposure, the developer, nature of bromide of silver (1) and of binding materials, &c., yet it is also influenced in a great degree by the time of development.

When the same kind of plates and developers are used, the density for one and the same exposure varies according to the time of development on keeping the temperature constant.

An investigation of this subject was made in the following manner:

As the developers edinol and ferrous oxalate of the following compositions were used, the former is known as a rapid, and the latter as a slow, developer.

1. Edinol Developer.

A.	{ Edinol (powder)	1 grm.
	{ Sodium sulphite	8 grms.
	{ Water, make up to	100 c.c.
B.	{ Potassium carbonate	50 grms.
	{ Water, make up to	100 c.c.

For use 80 parts of A and 20 parts of B are mixed.

2. Ferrous Oxalate Developer.

A.—Saturated solution of ferrous sulphate containing 2 per cent. citric acid.

B.—Saturated solution of neutral oxalate of potassium. For use, 20 parts of A and 60 parts of B are mixed.

The exposure was carried on the following way:—

Four narrow pieces of an ordinary dry plate (the extra rapid dry plate of Lomborg was used) were loaded in a slide casset. Each 1 cm. of the four pieces was exposed at the same time to a Hefner's standard amyl acetate lamp at a suitable distance, the exposure varying from one (Hefner metre seconds) to 153,600 (Hefner metre seconds) Two of the four pieces were developed with the ferrous oxalate developer and the other two with the edinol.

The time of development with both developers were selected as follows:

Series I.	10 seconds.
Series II.	20 ..
Series III.	40 ..
Series IV.	80 ..
Series V.	160 ..
Series VI.	320 ..

The exposed plates were developed always with a constant amount of developer at 18° C. After the development, the plates were laid in 20 per cent. thiosulphate solution for ten minutes and then were washed under running water for one hour.

The density was determined by the Marten's polarisation photometer, and calculated according to the formula given by Martens and Michéli(2).

$$Dr=2(\log \tan \alpha - \log \tan S)$$

Dr means the relative density of the developed plate; α , the angle of rotation of Nicols for the part of the plate the relative density of which is to be measured, when both semi-circles of the field of the photometer appear equally light; S, the angle of rotation of Nicols for the unexposed but developed part of the same plate.

Tables I. and II. show these results graphically. The curves are constructed in such a way that the ordinates represent the relative density, and the abscissæ, the logarithms of (i x t), i.e., the logarithms of the product of the intensity of light in u.m. and the length of the time of exposure in seconds.

TABLE I.
Edinol 18° C.

TABLE II.
Ferrous Oxalate 18° C.

he results show that:—

) The density of a photographic plate for an exposure the same length of time and when developed with same kind of developer increases according to the base of the time of development.

) When the time of development is short, there is great difference in the density by changing the effectual exposure $i \times t$.

i.) By increasing the time of development the density quotient $\frac{d}{\log i \times t}$ becomes greater.

r.) At an exposure for the same length of time the use of oxalate developer gives less density than edinol if the plate is developed for a short time; but when the plate is developed for a long time the former causes a greater density than the latter.

Comparing the relative densities at the corresponding exposures for the successive lengths of time of development following results were obtained:—

TABLE III.

Exposure [S.]	Edinol 18° C.					Ferrous oxalate.
	D_{T_2}/D_{T_1}	D_{T_3}/D_{T_2}	D_{T_4}/D_{T_3}	D_{T_5}/D_{T_4}	D_{T_6}/D_{T_5}	D_{T_6}/D_{T_5}
	1.50	1.29	1.75	1.61	1.38	1.77

13	1.512	1.566	1.734	1.601	1.739	1.708

Total mean = 1.630

Mean deviation = ± 0.085

, D_{T_2} , D_{T_3} , D_{T_4} , D_{T_5} , D_{T_6} mean the densities at the corresponding exposures for the lengths of time of development 10, 20, 40, 80, 160, 320 seconds respectively.

From these data the following *Exponential Law of Development* may be deduced.

Exponential Law of Development.

Within the range of the normal exposures, neutral density inclusive, the density ratio for any two lengths of time of development is constant and independent of exposure.

The density at a constant exposure is proportional to a certain power of the length of time of development.

The density at any exposure for the length of time of development $2 \cdot T$ seconds is equal to that of T seconds at the corresponding exposure multiplied by C , where C is a constant.

In conclusion, I desire to express my thanks to Professor Martens of the Technical High School of Hanover, for his assistance in this investigation.

Meeting held at Burlington House, on Monday, 1st May, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

THE CHEMISTRY OF WHISKY.

PART II.

BY PHILIP SCHIDROWITZ, PH.D., F.C.S., AND FREDERICK KAYE, A.R.C.S.C.

The present communication is a continuation of the work presented to the Society by one of us (Schidrowitz) some three years ago (this J., June, 1902, 814).

The secondary products in a spirit of any kind—referring to new spirit—are obviously dependent upon the nature of the raw materials or on the method of manufacture. As regards pot-still whisky the chief points of interest appeared to us to be the effect of the use of peat in kilning the malt, and the result of the fire-action in the still, that is, the effects produced by the impinging of a naked flame

on the liquid, and particularly the solid contents of the still. We were inclined to believe that a considerable part of the flavour of pot whisky is due to this fire-action, and, starting from this hypothesis, we obtained results of interest, but, for reasons stated below, we have had to materially modify our views in this connection. We thought that fire-action would necessarily produce dry distillation in some more or less modified form of the solid particles in the still, which, notwithstanding the use of stirring apparatus, must, in part, be in close proximity to the still bottom. These solid particles consist mainly of woody or cellulosic material derived from the grain, and of yeast. It occurred to us, that by exaggerating this fire-action by suitable methods in the laboratory, we might obtain, in relatively large quantities, those substances which are formed in minute amount in the still. The simplest yet at the same time the most radical way of testing this view was to dry distil material identical with or similar to that present in the solid shape in the working still. The products resulting from the dry distillation of woody matter are well known, and we therefore confined our experiments in this regard to the dry distillation of distillery yeast, respecting which we could find no information in literature. A large number of experiments in this direction were made both in the laboratory and on a working scale. Briefly stated, the products obtained are somewhat similar to those formed on distilling bones. They consist mainly of tar bases (fatty amines, and of the pyridine and pyrrol series), tar acids (phenols), a large

1) Vogel. Handbuch d. Phot. Bd. I., (1890) 159; v. Die Entwicklung, 9 (1901).

2) Martens and Michéli. Archiv. de Genève (4) (1901) 12—487.

proportion of nitriles, of neutral hydrocarbons, of organic sulphur compounds (mercaptans), of ammonia salts (chiefly carbamate and chloride), sulphides, thiocyanates, and a large volume of gases consisting chiefly of carbon dioxide, sulphur dioxide, and sulphuretted hydrogen. Having obtained these results we proceeded to examine new pot whisky, with a view to ascertaining whether any and which of these substances were present in the same. In this we were partially successful, for we obtained direct evidence of the presence of pyrrol, of phenolic bodies, of an alkaline substance (probably an ammonia salt), of sulphuretted hydrogen, and of sulphurous acid in different whiskies. We are also inclined to think that new whiskies contain traces of nitriles, but the definite identification of these substances in spirits is attended with so much difficulty that we prefer not to mention this otherwise than as a mere suggestion. The work of identifying more closely the substances mentioned, and of estimating some of them, if possible, quantitatively, is being carried on, but progress must necessarily be slow in view of the minute quantities in which they occur.

It will be noticed that all the substances mentioned as having been detected are such as would tend to become changed in time on exposure to air and moisture. Pyrrol under the conditions of cask storage probably resinifies, and this action would no doubt also apply to any other substances of a similar nature that may be present. The phenols may, and probably would, interact with the aldehydes, acids or alcohol to form condensation products, the sulphurous acid and sulphuretted hydrogen would naturally oxidise, and nitriles, if present, would certainly and rapidly condense or be transformed into acids. We have not been able to detect any of the substances alluded to in mature spirit. These facts appear to us to form the basis of a more rational view of maturation than has hitherto prevailed, and although we do not suggest that the maturing process consists merely of the disappearance or transformation of the substances alluded to—in view particularly of the fact that we are aware that material changes take place with regard to the better-known constituents, such as furfural, the acids, aldehydes, &c.—yet the disappearance of these substances would certainly appear to account in part for the elimination of the raw and unpleasant character of new, and more particularly of new pot, spirit. Bodies such as these might well be, in conjunction with the aldehydes and furfural, accountable for the curious effects which are attributed to immature spirits.

The basis of the experiments which had the results mentioned above was the assumption that fire-action was one of the chief, if not the main, cause of the production of the characteristic products in pot spirit. In view of the results obtained, this hypothesis might, at the first glance, appear to have received substantial confirmation. We have, however, already stated that our opinion in this respect has undergone considerable modification, and the reason for this is that we have come across pot whiskies—the samples were taken personally by one of us at the distilleries—distilled by means of slightly superheated steam, the latter being applied by means of a steam jacket, which, as far as we have been able to determine, do not differ materially as regards the specific nature of the secondary products contained, from whiskies distilled by the more general direct fire process. This fact undoubtedly disposes of the assumption that furfural, to mention one of the better-known substances, the formation of which is usually attributed to fire-action, is due to the latter, and in this regard the presence, as found by us, of furfural in appreciable quantities in grain whiskies, proves that this substance is not only not attributable to fire-action, but that it is not a specific indication of pot distillation. Since we have discerned no material difference between the specific products of fire and steam-distilled pot spirits respectively, it is obvious that the formation of the substances alluded to above—and found by us on the assumption that they are due to dry distillation—is not due to fire-action in the still. We presume, therefore, that, as far as they are obviously specific dry distillation products, they are derived from the peat and coke used in malting, or from the action of the hot gases on the kiln during the drying-off stage.

The results of the analyses are given in detail for the following reasons:—(1) That it is only by this method that the interesting and important differences, frequently of a very wide nature, between spirits of the same class and of different classes can be properly illustrated, and that it is only thus that the results can obtain technical importance; (2) that the number of full whisky analyses published so far is very small; and (3) that this is the first publication, to the best of our knowledge, of a large number of analyses of properly authenticated samples of any spirit whatever, be it of brandy, of whisky, or of any other potable spirit.

Method of taking samples. In order to make certain our material, all the samples were drawn at the distillery straight from bond, and duly signed or sealed by the authorities in charge. A great number of the samples were drawn by one of us, the remainder were obtained from us (also from bond and authenticated in each case as above) by an agent of our own. In every case, the samples were drawn and submitted to us with the full knowledge and approval of the distillers. We take this opportunity of thanking the proprietors of the various Highland and Lowland malt, Campbeltown, Islay and Grain whisky distilleries, not only for their kindness in providing us with samples, but also for the facilities they afforded us in viewing without restrictions the materials employed, the apparatus in use, and the methods of manufacture generally.

The methods of analysis employed were in the first place those set out by one of us in the first paper on this subject in this J. (*loc. cit.*). With regard to the higher alcohols, it was stated in the paper alluded to that the colorimetric method, as devised by French investigators for the analysis of brandy, did not give satisfactory results, inasmuch as the shade of colour obtained when operated on whisky differed sensibly from that given by the control—namely, isobutyl alcohol. It was suggested at the same time that the difficulty might possibly be got over by using a more suitable control, and we have now found that this is the case if, instead of isobutyl alcohol, amyl alcohol (isobutylcarbinol) be employed. This substance gives satisfactory results as far as shade of coloration is concerned, but we are very strongly of opinion that the colorimetric process can give really accurate results, not only for the reason that—as Bell has shown—the higher alcohols in whisky consist of a mixture of different alcohols, these, no doubt, varying in every individual case, and that it is well known that the coloration produced by the various higher alcohols with sulphuric acid varies enormously in intensity (*cf.* Allen J. Fed. Inst. Br. III., 1, 21). Thus, neither of the propyl alcohols gives a coloration with sulphuric acid and this, no doubt, accounts for the low results obtained in the case of the grain whisky. Moreover, there is some reason for believing that other substances besides the higher alcohols come into play in this reaction. This is (*cf.* Allen, *loc. cit.*) certainly the case with regard to the higher esters, and substances such as pyrrol and the terpenes; the great class of bodies grouped under the name of "essential oils," would undoubtedly be affected. Nevertheless, we have given the results obtained by the colorimetric process as modified by us, for we think that it may, when compared with the Allen-Marguardt results, afford some rough indication of the quantity of the higher esters, terpenes and other substances, to which we cannot yet give specific numerical expression, present. In order to make the results obtainable by the colorimetric process comparable as far as possible with those recorded in literature as obtained (chiefly in the case of brandy) with an isobutyl alcohol standard, we made some experiments to ascertain the relative intensities of colour obtained with this alcohol and with amyl alcohol respectively. The shades produced are not absolutely comparable, but if the figures given by us be divided by 2.5, the results will roughly approximate to those that would be obtained if an isobutyl control solution were used.

The analyses tabulated below comprise spirits from different distilleries. Each distillery is indicated by number, and where more than one sample from the same distillery was examined, an alphabetical letter is added. For obvious reasons we have refrained from referring

stilleries by name. A few words with regard to the
fication, and the method of manufacture of the
ent classes, may be of interest. The classification is
adopted by the industry concerned, and may be broadly
cterised as indicating varieties of the same genus:
Highland Malts are produced (if we except a few
eries on the islands in the west and north) in the
ct on the mainland lying north of an imaginary line
a through Dundee on the east and Greenock on the
west.
The malt is coked either with peat alone, or with
ture of peat and coke. *The Lowland Malts* are made
of the imaginary line alluded to. Less peat is used
e preparation of the malt, and occasionally, we
e, peat is dispensed with altogether, especially of
ears, owing to the growing taste for a spirit with a
ronounced peaty flavour. *The Campbeltouns* are
ed at the southern end of the Kintyre peninsula.
Islays are made in the island of that name. More
s used in the preparation of these whiskies than in
the other classes. We have laid some stress on the
it of peat used, as it is one of the few specific points
nufacture of which we have fairly definite know-
It must, however, not be assumed that the use
t alone is responsible for all the characteristics of
a whisky, for the Lowland malts in the preparation
ich little and sometimes no peat is employed, and
rain whiskies which are made without peat, yet
takeably possess those broad characteristics of
r which are associated with the article in question.
fferences between the various classes and individuals
same class are largely dependent, no doubt, on the
of the barley and other raw materials of a starchy
employed, on the water, the methods of malting

and distilling, the shape and manner of working the still,
&c. We hope, on some future occasion, to give an account
of an investigation in this direction. The *Grain* whiskies,
in the manufacture of which other cereal grains—partly
malted and partly unmalted—besides barley are employed,
are made in the district bounded by the Firth of Forth on
the east, and the Firth of Clyde on the west. The Grain
whiskies are distilled in a still designed for partial recti-
fication, but as will be seen from the figures below, they
are far removed from being silent spirits, and, as we have
already stated, they possess very considerable whisky
flavour.
Regarding the tables that follow we must mention
that the first column shows the age of the spirit in years and
months, and the letter following the age indicates the
nature of the cask employed for storage. In this respect
P. stands for *plain wood*; *R.* for *refill wood*, that is a cask
which was originally used for the storage of sherry, was
then employed once for storing whisky, was emptied
and again filled with spirit; *S.* for *sherry wood*; and
B. for *brandy wood*. The word *wood* is synonymous with
cask.
The brackets in cases of several spirits from the same
distillery indicate that the spirit was originally the same,
but placed in a different type of cask or submitted to
varied conditions of storage, &c., after distillation. Where
the age is given as identical, but the samples are not
bracketed, the fact is indicated that the different spirits
were not taken from one and the same period, which is
the term applied to each separate distillation, but that
they were distilled within a very short time (a week or
two) of one another. The latter results are, of course,
not strictly comparable.

NOTE.—Results, excepting in case of alcohol, extract and ash, are expressed in grms. per 100 litres of Abs. Alcohol.

conclusions.—Looking at the above results, the first which strikes one is the very wide variation in regard to different constituents, not only between the different classes, but also as between members of the same class. The following table gives the maxima and minima in each taking all the spirits together regardless of age.

	Total Acid.	Non-vol. Acid.	Ether.
and malts	10—83	0—35	33—185
and malts ..	6—60	0—16	27—87
beltonws ..	12—100	0—28	53—140
.....	15—36	0—33	40—86
.....	3—69	0—26	20—55

The same applies to any of the other figures taken singly, but at the same time, those spirits which have the greatest reputation commercially, all show a certain "balance" of the figures, taking them as a whole, and class for class, which, in our opinion, augurs well for the role which the chemical technologist in the future will

Higher Alcohols Colorimetric Method.	Higher Alcohols Allen-Marquardt Method.	Aldehydes.	Furfural.
328—864	112—235	4—66	1.6—6.3
189—897	82—228	8—54	0—5.2
357—930	160—259	11—85	2.1—8.0
620—740	155—200	17—40	3.8—5.2
39—400	33—80	trace—17	0—0.9

In regard to the effect of maturation we have not up averages for all the classes, as up to the present we have not been in a position, excepting in the case of the whiskies, of examining a sufficiently large number of corresponding old samples to make averages in this at all representative. In regard to the grain spirits, the averages for old and new samples respectively follows:—

	Total Acid.	Non-vol. Acid.	Ethers.
New ..	4.7	0.0	33.5
Old ...	38.5	10.6	38.2

be able to play as an aid to the distiller and blender. Whiskies such as Nos. 5, 8, 12, 15, 17, 18, 21, and 24 (to confine ourselves to one class again) which all show either an excess or a deficiency of certain constituents chemically regarded, are all known to possess commercial characteristics which make them unsatisfactory in some respects particularly in regard to their use as "self" whiskies (i.e., in an unblended state), as far

Higher Alcohols Colorimetric Method.	Higher Alcohols Allen-Marquardt Method.	Aldehydes.	Furfural.
113.2	49.3	5	trace
151.1	56.2	6	0.24

It will be noticed that the old samples show marked differences from the new, in the case of the non-volatile acids, and the substances indicated by the colorimetric process, and slight, though appreciable differences in the ethers, the higher alcohols, and the furfural. Aldehydes alone—contrary to our expectations—show no change. So far as we have been able to examine specimens of the other classes these conditions of appearance to be universal, but we prefer, at present, to express no definite opinion in this respect. On reference to the tables it will be seen that the type of cask used to exercise considerable influence on the maturation. We hope to say more about this on a future occasion, but meanwhile we may remark that the differences noted in this respect appear to affect not only the acid, the products indicated by the colorimetric process and the aldehydes, and that the sherry cask to hasten maturation as compared with other types. Of very great interest are the results concerning the effects of storage in a damp and in a dry atmosphere respectively are plainly evident. It is too, from No. 40, that the condition of the cask—its material and the nature of the wood—is of influence.

as the taste of the average consumer goes, but valuable by virtue of this excess or deficiency, where other considerations are in view. We have good reason to think that, as is the case with regard to wine or beer, certain of the chemical figures either of themselves or in groups, connote specific attributes, such as "body," fullness of flavour, delicacy, softness and so on, but, as a discussion of these matters is scarcely likely to be of general interest we refrain from going into them further.

Manchester Section.

Meeting held at Manchester, on Friday, May 5th, 1905.

MR. J. CARTER BELL IN THE CHAIR.

RECENT ADVANCES IN THE ELECTRO-METALLURGY OF IRON AND STEEL.

BY R. S. HUTTON.

INTRODUCTION.

The belief is still far too prevalent amongst those responsible for the introduction of new industries in Great Britain that because of our very limited endowment of water-power, electro-chemical undertakings are altogether unpromising.

This matter deserves much closer attention than it has yet received. Above all it should be remembered that the cost of power is frequently but a small fraction of the total cost of production. The accompanying table, whilst only a rough approximation, will at least serve to point out the very wide differences which exist in the power expenditure and value of different electro-chemical products.

Product.	Yield per H.P. Year in Tons.	Approximate Value per Ton.
Copper refining	15 to 24	68
Caustic soda	1.4 to 2.4 (75 p.c.) also 3 to 5 bleach	10 NaOH
Potassium chlorate . .	0.5 to 0.8	32
Calcium carbide	1.2 to 2.0	13
Ferro-chromium	—	—
70 per cent. Cr. . . .	0.8	—
Aluminium	0.25	130

We have next to consider what data can be brought forward as to the actual cost of power generation in this country.

Many of our leading electrical engineers have published minute figures as to the cost of power generation, but only for electric lighting, traction and motor purposes. These cases, however, are so entirely different in character from those we are concerned with that no definite conclusions can be drawn from this evidence. The average power station is fortunate to get a 15 per cent. load-factor and a very good one with 30 per cent., whereas in nearly all electro-chemical works the manufacture is continued night and day throughout the year, and the load factor may be taken as 100 per cent.

It one may judge from the evidence of those few who have had actual experience in electro-chemical industries using steam power, a figure of £6 to £8 for the h.p. year is quite attainable under such conditions. With producer gas this may probably already be brought down to £4 in this country.

For the sake of comparison, it may be pointed out that although in some few places in the Alps and Norway a figure as low as 17s. per h.p. year has been attained, water power is very seldom to be obtained so cheaply. At Niagara, the price of supply to large consumers varies from £3 11s. to £4 3s. and at Rheinfelden reaches £6 for the h.p. year.

So far as blast furnace gas is concerned, no very sure data are available for similar industries. The supply of cheap gas power is likely to prove so beneficial to our own country in the application of the industries we are about to consider that it is earnestly to be hoped that those who are concerned in the construction of large gas engines will be led to take an interest in these developments. With their co-operation, the number of remunerative electro-chemical industries may be very largely increased in this country.

Electro-thermic Reduction of Iron Ores.

The application of the electric furnace to the metallurgy of iron, with the exception of some few small scale experiments which are more of historical than technical interest, may be said to be largely founded on the experience gained in the manufacture of calcium carbide. Carbide furnaces have been and are being largely used for the production of rich ferro-alloys such as ferro-chromium and ferro-silicon, and in this way electro-

metallurgy has already been of considerable service to the steel industry.

As the production of calcium carbide became less and less remunerative, and as the demands of the market for these ferro-alloys became satisfied, definite attention was made to tackle the problem of the direct reduction of iron ores.

It might seem to be rather a hopeless task with the electro-metallurgist has thus set himself; for direct competition with the blast furnace is obviously on the question so far as our own and probably all other present iron producing countries are concerned.

On the other hand, there are certain advantages which can be gained by electric heating, and, although electric reduction of iron ores is at the moment unremunerative, we may expect to hear more of it in the future, when the general development of electric furnace construction is more advanced.

Every ton of pig iron produced in the blast furnace requires very nearly one ton of coke for its production. Of this amount, only one-third is necessary for the chemical reduction of the ore, the balance being employed in producing and maintaining the requisite temperature. This two-thirds of the fuel supply can be replaced by electric heating.

To take the very simplest case. For the reduction of pure oxide of iron.

Theoretically—
1420 kilos Fe_2O_3 For production of 1000 kilos.
322 kilos. Carbon

	Calories
For reduction of Fe_2O_3	1,780,000
For heating and fusing iron maximum	430,000
	2,210,000

By oxidation of 322 kilos. C. to CO 778,000
By oxidation of 322 kilos. C. to CO_2 2,603,000
Leaving to be supplied by electric power 1,432,000
= 1657 K.W.H. = 2220 H.P.H. = 0.253 H.P.Y.
per metric ton of pig iron.

In actual practice, so far, only the simple case of reducing the ore and allowing the carbon monoxide to pass unused has been tried, and with this process the following results have been obtained. Various methods, however, have been proposed by Héroult, Harmet, and others for utilising the total heat of combustion of the gas. Under these conditions, it should be possible to reduce iron ore with a much smaller power expenditure. The perfecting of methods along these lines is a matter for the future.

Recently, thanks to the foresight of the Canadian Government, a Commission was sent to Europe to investigate the electrical methods of producing iron and steel, and their report gives us valuable independent evidence of the power expenditure in the various processes which they studied.

Actual results in practice:—

Power Expenditure per 1000 Kilos. Product.

	Mean Power on Furnace. K.W.	K.W. Hours.	H.P. Year
(1) Keller (Canadian Commission)—			
A. Grey pig (4.2 per cent. C., 2 per cent. Si.)	613	3420	0.522
B. White pig (3.0 per cent. C., 0.7 per cent. Si.)	226	1620	0.25
(2) Stassano (Goldschmidt)	80	3155	0.48
(3) Héroult (Canadian Commission)	182	3380	0.517
(4) Morrison	270	2233	0.34
For comparison with these figures:—			
(5) 70 per cent. Ferro-chromium Willson Al. Co. (Haber)	300?	7950	1.21
(6) 30 per cent. Ferro-silicon Willson Al. Co. (Haber)	300?	5930	0.91

In connection with this table, the following remarks may be made. In experiment (1) A., nearly 10 tons of grey pig iron manufactured during a 55 hours' run some 28 taps being taken from the furnace. 15,943 kilos. of ore were charged on 54.1 per cent. Fe.

In (1) B., about 6½ tons of pig were produced in 48 hours, but the energy consumption being kept low, only a very small quantity of the impurities in the ore was reduced. The average amount of coke used per metric ton of product in the two experiments was 370 kilos.

In (3): This was a very small scale experiment, less than 1 ton of metal being obtained in 16 hours, the ore was more poor grade, containing about 35.5 per cent. iron, it is therefore surprising that the power expenditure was not higher.

For (5) and (6) it must be remembered that both chromium and silicon oxides require a very much higher power consumption for their reduction (1 kilo. silicon from SiO_2 requires 6414 Cal. as compared with 1780 Cal. for 1 kilo. iron from Fe_2O_3).

F. W. Harbord, the metallurgist attached to the Canadian Commission, ably summarises the present position of the electric reduction of iron ores, "iron can be produced on a commercial scale to compete the blast furnace, only when electric energy is very cheap and fuel very dear. On the basis taken in this report, with electrical energy at 10 dols. (41s. 8d.) per h.p. and coke at 7 dols. (29s. 2d.) per ton, the cost of production is approximately the same as the cost of casting pig iron in a modern blast furnace." It is even if electric reduction can be successfully effected in such countries as Chile or Canada, where power is abundant and fuel expensive, there is no bright prospect for it in our own country.

Electric Steel Production.

Considering this subject it is necessary to judge the furnace methods entirely on their own merits and according to whether they approach more or less to the usual metallurgical process they are proposed to displace. The whole *modus operandi* of an electric furnace is so different from that of a fuel heated furnace that its advantages and disadvantages are apparent if judged by a direct comparison of the two methods. It is rather from the product which results in the two cases and from the methods of production that conclusions should be drawn. In the last two or three years much has been accomplished. Experiments have been carried out on a commercial scale and by those who have had a very wide experience in electric furnace work. So that what we have to consider are data obtained in working over long periods, confirmed in most cases by actual tests undertaken by the Canadian Commissioners or independent witnesses.

The most important consideration is the power expenditure. This is briefly summarised in the annexed table. However, almost equally important to consider is the quality of the steel manufactured, as also the nature of the raw materials required for production.

Electric Steel Processes.

Authority.	Power on Furnace K.W. Approx.	Materials used.	Yield (per day) Approx.	Power Expenditure per 1000 kilos. Product.

* Not actual test runs.

In the first place there seems to be good evidence to show that steel, equal in quality to the best Sheffield steels, can be produced in the electric furnace. This can be accomplished either in such a furnace as that of the Heroult, in its present form, is used almost entirely with carefully chosen raw materials, and does not require considerable refining of the material. On the other hand with the Heroult furnace such a product can be obtained starting with almost any grade of raw material, this process relying essentially on its capability of completely refining pig iron or ordinary steel. The economical advantages of using a small electric furnace for producing high quality steel will doubtless tell in favour of such a

method. It is largely to such possibilities of refining, and to the relatively high cost of fuel per ton of product for the manufacture of crucible steel, that the electric processes owe their advantages.

From the table it will be seen that in nearly all the examples given the whole operation of melting and refining the raw material has been effected by electric heating. In our own country where coal is cheap it is almost certain that much of this heating could be more economically carried out by the combustion of fuel. In the case where molten iron or low grade steel can be run into the electric furnace, it will be seen that the power expenditure required for refining it and bringing up its quality to that of a crucible steel is indeed very low. Along such lines as these, the electric furnace may be expected to find still wider applications than to the manufacture of high grade crucible steel.

Space does not permit of a detailed description of even the more important furnaces which are being used for steel manufacture. The following notes will, however, serve to point out some of the recent progress which has been made, and a short list of publications is given which will enable the reader to obtain further details of the several processes.

Heroult Furnace.

At La Paz in the South of France, a 3-ton furnace has been regularly working since the end of 1900, and has turned out more than 3000 tons of high quality steel. More recently a plant has been installed at Korfors in Sweden, whilst within the last few months a company has been floated in Germany with £50,000 capital, to work the Heroult steel process. At the present time a 50-ton furnace is in course of construction at La Paz, where also other developments of the method are being perfected.

Kiellin Furnace.

This has been worked for some years at Gysinge in Sweden, and the German rights have been recently taken over by Siemens and Halske, of Berlin. The 170 K.W. furnace is capable of turning out over 5 tons per day, and with a 736 K.W. furnace now under construction, it is hoped

to raise this to 30—36 tons. Recent improvements enable refining of the crude steel to be satisfactorily accomplished by adding the necessary amount of iron ore to the slags.

Other Furnaces.

At Livet the Keller steel furnace was shown to the Canadian Commission and seems to be very similar in function to that of Heroult. Captain Stassano has continued his work with the rotating furnace in which the materials are heated by radiation from an arc which is maintained above their surface. In this furnace, both iron ore reduction and steel production have been carried out on a satisfactory scale. The crucible furnace of P. Girod of Courtepin (Switzerland), and Ugine (Savoie),

has been used almost exclusively for the manufacture of high grade ferro alloys such as are required for the manufacture of special steels. Its ingenious construction may, however, render it of still wider application.

Gustave Gn has considerably modified his original process of steel production by arranging the narrow channels, in which the metal is heated by the resistance which it offers to the passage of the electric current, in direct connection with wide basins in which the refining is effected. This method is being applied at Plottenberg in Westphalia.

A somewhat similar modification has been adapted to the induction furnace by Messrs. Schneider and Co., of Creusot, narrow tubes surrounded by the high tension coils being arranged in series with a reservoir to which the metal to be treated is added and in which the refining is effected.

With these modifications many of the difficulties due to the rapid corrosion by the slags of the refractory lining of such narrow channels should be overcome.

Meeting held at Chemists' Club, on Friday, March 24th, 1905.

RUSSELL W. MOORE IN THE CHAIR.

GAS AS A SOURCE OF POWER.

GENERATION OF PRODUCER, MOND AND BLAST FURNACE GASES.

BY WILLARD L. CASE.

This paper claims little originality in itself: it is an arrangement of facts and data obtained from various authoritative sources; quotations are freely made from valuable papers read at one time or another before the Technical Societies, especially from the very practical papers of Mr. Alexander M. Gow and Mr. J. R. Robbins.

The gas engine has proved its worth and demonstrated its ability to work successfully on all our commercial gases, producing a conversion efficiency greatly in excess of that obtained by any other heat motor.

The problem of a fuel gas supply, of proper quantity and quality to serve a modern power plant, has worked itself out and down to the very basis you have outlined:—

"Blast Furnace and Coke Oven Gases"—by-products of extensive industries—for those power plants in localities adjacent to or which can be served from these works; "Producer Gases"—of which "Mond Gas" is one—for the average or general power plant installation.

The future progress of the gas engine depends upon all these three gases; but more particularly upon producer gas—a gas manufactured especially for power and possible of generation and use in any locality.

If we set forth, even in a general way, the specifications for an ideal power gas and note the general characteristics of the various commercial gases in comparison therewith,

we have evidence as to why this problem has so determined itself:—Very briefly, we want a gas uniform in quality and clean, containing a low percentage of hydrocarbon and inert gases; a gas capable of production in a process of the least complexity of apparatus and of the greatest simplicity in operation, and capable of production from the most readily available fuels and at the least possible cost.

To secure a gas of the greatest possible uniform composition, it is necessary that it be generated by a process which, more nearly than any other, maintains constant all conditions affecting its generation; for reason the process, in operation, should approach the continuous rather than the intermittent; the latter involves periodical alterations of generating conditions, and gas is an essential requisite, and therefore the gasification of the fuel should be wholly completed within the generator, and the gas leave the generator free from all impurities that cause trouble in the engine by scouring, fouling valves and cylinders; no cleaning apparatus, other than a simple scrubber for the purpose of removing dust held in suspension, should be required.

For the composition of the gases we would have a low percentage of inert gases and of free hydrocarbon, if possible—the reasons for which are evident—the more the gas, the less volume there is to be handled and stored; the lower the percentage of hydrogen the less will be the flame temperature of the mixture and the slower the combustion, which permits of higher degrees of compression and a consequent greater efficiency in the engine cylinder.

In order to produce a gas at the lowest possible cost, the gas plant must have the least complexity of apparatus and operation; there must be the fewest possible number of distinct operations and auxiliaries; for, while there are several by-product recovery systems which lessen the cost of gas production by the recovery and sale of other products, it is not advisable, nor is it desirable, for the average power plant to engage in operations entirely distinct from its own special field of work. Furthermore, the gas process itself must give a high conversion efficiency and must furnish a product under these conditions of the cheapest grades of fuel.

Before outlining the characteristics of the various commercial gases it may be advisable to first note some very general conditions.

All fuel may be converted into gas; but whether the gases of such a conversion are combustible or not depends upon the nature of the materials used and the method of their gasification.

The complete combustion of fuels produces incombustible waste gases containing carbonic acid and water vapor, nitrogen and possibly some oxygen of the air supply; their incomplete combustion produces, in addition to the combustible products containing hydrogen, carbon monoxide, hydrocarbons and possibly tar and smoke as products of distillation.

In the first process four operations take place—1. fuel elements are vaporized, distilled, gasified and burned; 2. the second, the fuel is vaporized, distilled and gasified; and this is the process of making fuel gas.

The commercial gases are designated according to the methods employed in their manufacture or to the raw materials used. They are: natural gas, retort gas, water gas, oil gas, carburetted water gas, producer gas, coke oven gas and blast furnace gas. These gases differ from each other in the proportion of their constituent gases, which are oxygen, hydrogen, carbon dioxide, carbon monoxide, methane, ethylene, nitrogen and sulfur in small quantities. The value of these constituents may be briefly noted:—Oxygen is not to be considered as having any heating value; to the extent it appears that much less oxygen will have to be supplied in order to burn the gas.

Hydrogen appears either as free hydrogen or combined with carbon as hydrocarbon. It has a calorific value of 320 B.T.U. per cu. ft.

Carbon dioxide has no power to produce heat; inert gas acting only as a diluent and reducing the value of the mixture.

Carbon monoxide has the same calorific value as hydrogen—320 B.T.U. per cu. ft.

thane has a calorific value of 1000 B.T.U. per cb. ft., a slow burning gas, and for this reason a particularly valuable constituent of a gas for engine use.

Hydrogen, often given as "Illuminants" in analysis, has a calorific value of 1600 B.T.U., but appears to only all extent in the commercial gases.

The illuminants or heavier hydrocarbons form a very small percentage of commercial power gases.

Hydrogen and sulphur have no heat value and act as a check to the mixture retarding its combustion and reducing its calorific value.

The typical analysis of the commercial gases, which sets forth their general characteristics follows:—

	Natural Gas.	Retort Gas.	Water Gas.	Oil Gas.	Carburetted Water Gas.	Producer Gas from			Coke Oven Gas.	Blast Furnace Gas.
						Anthracite.	Bituminous	Coke.		
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Hydrogen	3.0	46.0	48.0	32.0	40.0	20.0	10.0	10.0	50.0	1.0
Carbon monoxide	92.0	40.0	2.0	48.0	25.0	—	3.0	—	36.6	—
Carbon dioxide	3.0	5.0	—	16.5	8.5	—	0.5	—	4.0	—
Water vapor	—	6.0	38.0	—	10.0	25.0	23.0	29.0	6.0	27.5
Nitrogen	—	0.5	6.0	—	3.0	5.0	5.0	4.5	1.5	11.5
Oxygen	2.0	2.0	5.5	3.0	4.0	49.5	58.0	54.0	2.0	60.0
Sulphur	—	0.5	0.5	0.5	0.5	0.5	0.5	0.5	0.5	—

Natural gas has a calorific value of about 1000 B.T.U. per cb. ft. and requires 9.73 cb. ft. of air per cb. ft. of gas for combustion, the resultant mixture having a value of 91 B.T.U. per cb. ft.

Oil or coal gas, as it was formerly called, has a calorific value of 668 B.T.U. and requires 6.05 cb. ft. of air for combustion with a resultant mixture containing 91 B.T.U. per cb. ft.

Water gas from retort coke contains 295 B.T.U. per cb. ft. and requires 2.35 cb. ft. of air for combustion, the resultant mixture containing 88 B.T.U. per cb. ft.

Retorted water gas has a calorific value of 575 B.T.U. per cb. ft. and requires 5.25 cb. ft. of air per cb. ft. of gas for combustion, the resultant mixture containing 92 B.T.U. per cb. ft.

Gas contains 846 B.T.U. per cb. ft., requires 8.07 cb. ft. of air for combustion, and contains 93 B.T.U. in the resultant mixture.

Producer gases from both anthracite and bituminous coals, differing in analysis, have the same calorific value of 144 B.T.U. per cb. ft. The anthracite gas requires 1.12 cb. ft. of air for combustion, and contains 84 B.T.U. in the mixture, while the bituminous gas requires 1.2 cb. ft. of air, and contains 65.5 B.T.U. in the resultant mixture.

Water gas from coke has an average value of 125 B.T.U. per cb. ft.; requires 0.98 cb. ft. of air for combustion with a resultant mixture of 63 B.T.U. per cb. ft. Blast furnace gas has a value of 603 B.T.U. per cb. ft.; requires 5.6 cb. ft. of air for combustion, and contains 91 B.T.U. in the mixture.

Blast furnace gas has a heat value of 91 B.T.U., and requires 7.72 cb. ft. of air for combustion, with a resultant mixture containing 53 B.T.U. per cb. ft.

The values given for the air for combustion and for the resultant mixtures are based upon theoretical calculations. It is interesting to note that where the gases are not greatly adulterated by the addition of an inert nitrogen constituent there are an almost constant number of heat units available per cubic foot of explosive mixture.

Considering the use of these various commercial gases for power purposes, we must briefly note:—

Natural gas, very desirable for engine use, is restricted to localities. Coke oven and blast furnace gases, valuable engine gases, are by-products of extensive operations, and their production and utilisation are subject to the same.

Oil gas, and carburetted water gas are all valuable engine gases, but are too costly for general use.

As, as made in America, at least, is too expensive for general use, owing to the cost of raw fuel and the inefficiency of the producing systems; in addition

to this, is the apparent difficulty of its pre-ignition and back firing in the engine cylinder, due to its high percentage of hydrogen. This fact also prohibits that degree of compression which enables the system to operate at its highest efficiency. The raw fuel used in its manufacture is coke, and the process in general is similar to that employed in generating producer gas, except that the production of water gas is always intermittent.

In passing, it may be of interest to note that water gas processes are being exploited in Europe, which claim an efficiency of from 75 to 85 per cent. in the conversion process—I refer to the Dellwik-Fleischer and the Kramers-Aarts systems. It has also been stated by the syndicates

controlling these systems, that engine builders in Europe have overcome the difficulties of working on so high a percentage of hydrogen gas, that a number of engines are operating under a guarantee of a gas consumption not to exceed 31 cb. ft. of gas per horse power hour, while tests show a consumption of less than 28.5 cb. ft. This, according to claims of the syndicates above mentioned, is a horse power per hour per pound of coke, which they state they will guarantee.

If these statements are facts, it means that for the power problem, in certain special instances, we have another means of satisfaction. I do not refer so much to the generation of a gas for direct engine use (for coke in any one locality will always exceed in price that of an ordinary coal), but reference is made to the power problem in the vicinity of by-product coke works, where, instead of using 60 per cent. of the gas, given off by the coking coal, for heating the ovens and having available a surplus of only 40 per cent. for light or power purposes (or to let go waste as some of the plants now do) they make all the gas given off an available surplus by heating the ovens with water gas made from coke. In this way coke, for which there may be no satisfactory market, may be disposed of, and we have available from the coke plant, at small cost, a satisfactory engine gas which may be transmitted many miles without loss of energy and which may be utilised at any point or points along the distributing line for power. This, however, affects only the power problem in special fields.

For the general and average or the universal power plant proposition, it is evident from the brief resume of the commercial gases outlined that it is the producer gas process alone which is susceptible of the development desired—a process capable of universal application—such as producer gas has already proven itself to be.

While producer gas is low in energy, it is a very satisfactory engine gas, the presence of considerable quantities of inert constituents having no detrimental effect upon the operation of gas engines other than occasioning the special designing of ports and passages to accommodate the large quantities of gas used. The efficiency of the various producer gas processes ranges between 70 and 85 per cent., depending largely upon the design of the producer and its ability in completing the gasification of heavy hydrocarbon distillates. It is the cheapest of all the commercial gases, costing less to generate, requiring the least amount of apparatus auxiliary to the generator, requiring less attendance and utilising any available fuel to almost equal advantage—coke, coal, wood, the lignites, peat and other materials have already been used successfully.

There are many variations in the methods and apparatus employed for generating producer gas. In general the

process consists in simply passing air, or air and steam, through a body of fuel, enclosed in a suitable brick-lined generator; usually the process is a continuous one, fuel being fed as needed and the steam and air blasts being introduced simultaneously.

In the ordinary producer, when coke or anthracite coal are the fuels gasified, the gas comes off comparatively clean and requires little scrubbing for use in gas engines; when bituminous coal is gasified the gas is extremely dirty, and contains a large amount of tarry vapours, so that it is necessary to thoroughly scrub it before it is adaptable to engine use.

It is because of this difficulty—the necessity of extensive scrubbing and cleaning systems with gas made from bituminous coal—that practically all our producer systems, generating a gas for engine use, operate on anthracite or coke.

A typical analysis of producer gas from anthracite and bituminous coals and coke is that indicated in the foregoing table; both the coal gases have a calorific value of 144 B.T.U. per cu. ft., while the coke gas has a value of 125 per cu. ft. This difference in heat value is due to the raw fuel used and the resultant necessary methods of gasification—notably the amount of steam introduced and decomposed.

All three gases show about 5 per cent. of carbon dioxide, owing to the burning of some of the carbon monoxide, but to make a gas even of the above analysis demands that the producer be kept in the best working condition and handled with skill.

It was stated that the efficiency of the producer gas process varied from 70 to 85 per cent., according to methods and apparatus employed. The efficiency in any instance may be determined by dividing the net heat output by the gross heat input; or calorific value of gas per cu. ft. \times gas yield per lb. of fuel—calorific value of fuel used per lb.

As an example of the efficiency attained in average producer practice, it may be interesting to call attention to a summary of investigations for producer practice made at the works of the Pennsylvania Steel Co., Steelton, Pa.

The coal used was bituminous, containing carbon 75.68 per cent., ash 7.12 per cent., moisture 4.00 per cent.

Its heat value per lb. was 14,920 B.T.U. The amount of gas made per lb. of coal was 70.15 cu. ft. Its composition by volume was (dry gas)—

CO ₂	5.7
CO	22.0
CH ₄	2.6
C ₂ H ₄	0.6
H	10.5
O	0.4
N	58.2

Its calorific value per cu. ft. was 154.5 B.T.U. The efficiency of conversion was 78.4 per cent., as follows:—

	Per cent.	
Amount lost as carbon in ash	2.1	of value of coal.
Amount lost by radiation and conduction ..	5.1	" "
Amount lost in sensible heat of steam ..	0.7	" "
Amount lost in sensible heat of dry gas ..	13.7	" "
Amount of total loss	21.6	" "
Amount made available in producer gas ..	78.4	" "
Total value of coal	100.0	" "

Before noting the several methods and various types of apparatus used for generating producer gas it may be interesting to point out what is desirable in the way of a producer.

First of all, we would like to have a continuous gasification process, *or*, as was previously noted, a process that involves the least possible alteration of condition affecting generation; it must be a process and apparatus capable of wide demands in the way of output without serious variations in the quality of the gas; the variable loads of general power service demand this.

The producer, or generator, should be provided with a continuous fuel feed in order to preserve therein a

uniform depth of fuel; this feed and its mechanism should be positive, adjustable and easy running.

The producer should carry a fuel bed of considerable depth to insure uniform gas and complete gasification and means should be provided for maintaining a fuel bed and preventing packing so that the resistance to the blast and the irregularity of the process are minimised.

An ash bed, of sufficient depth to prevent loss of fuel and of internal heat, should be kept beneath the bed; means should be provided for the removal of without detrimentally disturbing the fuel bed.

The steam and air blasts should be so introduced as to secure uniform distribution below the fuel bed and throughout its whole body.

In addition to this we would specify for this producer a requirement which no single producer or generator on the market can now satisfy. It should be so constructed that, by a simple operation, it should effect the conversion into fixed gases of all the combustible constituents of bituminous coal, and deliver a gas for use that needs no cleaning other than the removal of dust.

As regards the various types of producers in operation, they all consist essentially of a cylindrical shell lined with fire brick and provided with a sealed feeding hopper at the top; a gas offtake at the bottom; a central or transverse tuyère for the steam air blast, and a fixed bar grate or a revolving hot water seal, for removing ashes while the producer is in operation.

There are four distinct methods of operation and a consequent modification of producer design to suit them, *viz.*:—

Producers, operating to furnish an engine gas, the first method, successfully handle anthracite coals in some cases also, the semi-bituminous coals, provided the proper additional scrubbing appliances are used in the latter.

The second method is a recent development, and has for its object the generation of a gas at the precise rate demanded by the load upon the engine; and for this purpose the engine is arranged to furnish the suction at the producer, upon its inspiration stroke. In employing this method, coke or anthracite fuels are the materials gasified.

The re-entrant method was adopted for bituminous coals with the object of gasifying the tar vapours from the producer. By this method the gases are not taken off from the top of the generator, but from openings considerably below the top of the fuel bed and about halfway down the chamber walls. It is claimed that this method, in the upper part of the producer, undergoes distillation to the coke stage; and the liberated tar vapours, which are forced to descend through the hot fuel bed to reach the outlets, are largely broken up into fine droplets, but this is only partially true, for it is admitted that the method is not suitable for gasifying coals of a highly coking nature.

The last-named method, the intermittent system, as developed in the Loomis-Pettibone Producer, is a new method in producer practice by which we can continuously gasify bituminous coals and produce therefrom a gas suitable for engine use without extensive secondary cleaning apparatus. Two generators are employed, connected in series at the top, and provided with independent outlets at the bottom.

In general, the process follows that of water-gas making on the blow, the generators operate in parallel; at the top of the generator and comes into contact with the fresh fuel; the products of combustion, together with any distillates from the fresh fuel, are drawn downward through the deep charge of incandescent fuel and through the bottom of the producer; they then pass through the boiler, where their high temperature is utilised to generate steam; they are further cooled to about atmospheric temperature in their passage through the water-sprayed, coke-filled trays of the holder, whence they pass to a special holder.

When the fuel bed has been raised to the desired temperature, the air blasts are discontinued; an effect

isting the valves and throwing the generators in series, m is admitted under the grate in one generator and is ocated at the temperature of the fire, forming water-on its passage up through the hot fuel bed, across the connecting pipe to the second generator and down ough the latter; it then passes out from the bottom as generator to the boiler, the scrubber and water gas-er. The next time water gas is made the direction of un is reversed—the advantage of which is evident. The versed—the advantage of which is evident. The s are finally properly mixed in the desired proportion engine use.

re essential feature of this arrangement and process is, with bituminous coals, the tar vapours, liberated the green fuel in one generator, are forced through ot fuel bed of the second generator, where they are orted into fixed gases.

is system has other important advantages. While generators are employed the apparatus of the plant pact, simple and efficient in operation, and it readily its itself to varied and wide demands; and, when ed to gas generation for power purposes, has proved eable, under all rates of production, of maintaining nearly uniform conditions in the fuel bed which are rial to a gas of uniform quality.

haps no better idea of the capabilities of the system a direction can be had than by briefly quoting from a y by John Langton, read before the American Institute ing Engineers in 1903. It refers to the power plant e Moctezuma Copper Co., Nacozari, Mexico. The r plant consists of eight gas engines, each direct l to a 65 kw. direct current generator.

he original intention was to make producer gas and gas at Nacozari in the usual manner, by alternate ug and steaming; but in a plant operating only one producers, as at Nacozari, the quality of the mixed as too variable. The method of gas making was re modified by introducing steam pipe connections, ing graduated regulation, to permit the introduction am together with the air to the top of the fire; and s means the excess heat of the fire, caused by the air ug, was concurrently used to make water gas. But ler to maintain the necessary state of equilibrium an adjustment of air and steam, rather too fine sy every-day working, for which reason the method red is to admit somewhat less top steam than could d, in order to allow the fire to increase slowly in tem- re; and then, without allowing the temperature ome excessive, to make a short water gas run, which ightly pulls the fire, and to resume immediately the g of mixed gas from top steam. This also dis- is the heat more uniformly throughout the column , and in a manner shakes it up enough to prevent mation of holes or masses of clinker. The water ade separately by this method and delivered into er gas holder, is gradually fed from the latter into in holder which supplies the gas engines, the water lder being weighted to give an inch or two greater re than that of the main holder. The rate of feed olled by a throttle valve, in a pipe connecting the lders, which the operator manipulates so that the feeding water gas approximately equals the rate duction. No particular accuracy is required, nor s taken to regulate the quantity of water gas made ely. The operator is governed principally by the ature of the fire, as indicated by its appearance, the rise of steam pressure on the boiler. If the fall water gas holder necessitates the making of water ore the fire seems quite hot enough, the throttle pening is slightly lessened, and *vice versa*. This is point which varies much during the day or even ay to day.

his method it has been found quite easy to make eh that the variations in its quality, shown by and calorimetric readings, have no observable effect e working of the engines or upon their efficiency." analysis of the gases made in the producer from ate and bituminous coals and wood is here indi- each analysis being the average of a consecutive test:—

	Anthracite Coal.	Bituminous Coal.	Wood.
	Per cent.	Per cent.	Per cent.
CO	21.60	21.32	13.27
H	12.68	13.08	20.97
CH ₄	1.86	2.35	2.61
CaH ₂	0.18	0.20	0.28
CO ₂	8.10	7.66	15.96
O	0.20	0.04	0.11
N	55.38	55.95	46.80
Calorific value (B.T.U.)	100.00 131.4	100.00 133.47	100.00 140.22

It is noted that, for more than three years, the gas plant at Nacozari has been furnishing the engines with producer gas made from wood and the entire plant is efficient and satisfactory.

In general, it may be said that whatever the nature of the gas used, an engine of proper design will consume 10,000 to 12,000 B.T.U. per brake h.p. per hour at or near full load. With producer gas of 125 B.T.U. per cu. ft. (the average value of anthracite gas) the consumption will approximate 80 cu. ft. per brake h.p. hour, and it is evident, from actual demonstration, that a well-equipped gas power plant, operating on producer gas from any of the coals should show a duty of at least 1 lb. of coal per indicated h.p. hour.

The stand-by losses of such a plant are very small in a good producer—the consumption of coal during these periods averages about 3 lb. of coal per hour in plants averaging only 250 h.p.

Mond Gas.

Mond gas, really a producer gas, is a representative of the ammonia recovery systems.

The fuel used is any description of free burning rough slack; it is claimed for the producer that by the use of an especially long fuel feeding bell, extending well down into same, the green fuel therein undergoes distillation, resulting in the removal of the tar vapours by forcing them down through the hot fuel bed, but this is subject to limitations, for a coal of strongly coking nature is not desired, nor is it suitable for use in this producer.

The advantages of the Mond system are the use of a cheap coal and the recovery of a valuable product—ammonia. Its disadvantages are that when arranged to recover ammonia from the coal a great complexity of costly plant, apparatus, and operation is demanded, that when installed without the recovery system, while producing excellent results, it is on the same basis as other systems which employ only one generator—*i.e.*, bituminous coals are not satisfactorily handled, especially if they be of a strongly coking nature.

The Mond system may be an attractive proposition for just such an installation as they are now making in Great Britain, where a central generating station of 40,000,000 cu. ft. daily capacity will distribute this gas to numerous towns and through a district covering 123 square miles. This is one of five contemplated stations of like character to complete the system within this district, but it would seem that so extensive a field were really the province of the by-product coke oven plant, and that the Mond recovery system fitted best that proposition about half way between the coke oven and the ordinary producer gas systems.

The apparatus of the Mond system is briefly noted in the description of the gas-making process, following.

The producer is provided with a water seal, and is so constructed as to allow the ash, which is the only residue, to descend into the water, from which it is easily removed without interfering in any way with the working of the producer.

The process of combustion in the producer is carried out at a comparatively low temperature, with the two-fold object of preventing the formation of clinkers in the producer, and of providing against the destruction of ammonia. This is accomplished by introducing into the producer a blast of hot air and steam. The quantity of steam required, when it is desired to recover the ammonia from the gas is equal to 2½ tons per ton of fuel gasified, but of this about one ton is automatically recovered, and

used over and over again. In those installations where ammonia recovery is not made the steam required is about one ton per ton of fuel.

After leaving the producer, the gas passes through a regenerator so arranged that part of the heat of the gas and steam entering it is transferred to the blast of air and steam on its way from the air-heating tower to the producer, the gas being consequently cooled to a corresponding temperature.

After leaving the regenerator the gas is delivered to a mechanical washer, where, by intimate contact with water, the temperature of the gas is further reduced, and all soot and dust are removed from it.

The next step is the recovery of the ammonia contained in the gas, and for that purpose it is passed through an acid tower where the ammonia is completely absorbed by a dilute solution of sulphuric acid. This acid solution circulates through the acid tower again and again until it contains from 36 to 38 per cent. of sulphate of ammonia. Continuity of the process is provided by adding, from time to time, fresh supplies of sulphuric acid and withdrawing corresponding quantities of sulphate liquor, which latter are then evaporated, yielding solid sulphate of ammonia of good saleable quality.

After the gas has been washed of its ammonia products, it passes through a final cooling and cleaning water-tower and is then ready for use. As the gas is cooled in this final tower the steam with which it was burdened condenses, and the cleaning water, which entered the tower cold, is delivered hot; and this, after passing through suitable tar separators, is again pumped to the air-heating tower, where it serves to heat the air required for the producer blast.

Into the air-heating tower a blast of air is forced by a blower, and, in its contact with the descending stream of hot water, becomes heated and saturated with vapour; it is thence carried through the regenerator and to the producers as already noted.

The water which was delivered hot to the air-heating tower, after heating the blast, is drawn off sufficiently cold to be returned to the top of the gas cooling tower to repeat the cycle.

This method of continuously employing the water in circulation as the heat carrying agent between the hot gas in one tower and the cold air in another, and the method of recovering from the hot gas, by this continuous cyclic exchange of heat, a large proportion of the steam required for the producer blast, are important features in the economy of this process.

The distinctive feature of the entire process is the economic production of a good engine gas from very cheap coals; the economy of the process being very greatly enhanced by the recovery of ammonia and its conversion to a saleable ammonium sulphate.

The Mond system as installed for power plants under 5000 h.p. does not warrant the installation of the ammonia recovery process.

The following is a typical analysis of Mond gas, being the average of several analyses at plants with and without the recovery system:—

	Without Ammonia Recovery	With Recovery.
	Per cent.	Per cent.
CO	11.0	13.8
H	27.5	24.3
CH ₄	2.0	2.0
CO ₂	16.5	13.9
N + H ₂ O	43.0	46.0
	100.0	100.0
Total combustible in the gases	40.5	40.1
Calorific value	145.6	144.2

The coal used was slack, with an average analysis in both instances of:

	Per cent.
Moisture at 100° C.	8.6
Volatile matter (excluding carbon) ...	18.29
Total carbon	62.69
Ash	10.42
	100.00

The calorific value of the dry fuel was 12,213 B.T. per lb. The average production of gas per ton of fuel consumed, by either process, is about 140,000 cb. ft. of gas of a calorific value of 140 B.T.U. The efficiency of the process of fuel conversion does not fall short of 90 per cent.

Tests have demonstrated that this system is capable of producing power in a good engine with a consumption in the producer, of 1 lb. of coal per h.p. hour.

It may be interesting to note the stand by losses of the system:—

It is stated that the stand by losses of a 1000 h.p. plant are about 225 lb. of fuel per night of 14 hours, and when standing for eight days, they are at the rate of about 7½ lb. per day. After the week-end stoppage, the time required for starting is only three minutes for such a plant.

It is evident that, for ordinary installations, the waste of the Mond system approximates the average production of the plant; and for the large central power station it exceeds same by reducing the cost of power by the value of the ammonia sulphate recovered. It is claimed that a 20,000 h.p. plant under continuous operation, the production of ammonium sulphate will approximate nearly 3000 tons per year. The net profits of this, after deducting all costs of production, will approximate 1.75 dols. per ton of fuel gasified; this figure was slightly exceeded by the works of Messrs. Brunner, Mond and Co., England, during a 12 month operating period. At the "Mond" plant in America, where 150 tons of coal are gasified per day, it was found that the value of the products recovered, after deducting the cost of labour, repairs and chemicals required, reduced the cost of fuel to some 50 cents per ton to the plant.

Blast Furnace Gas.

It has been stated by reliable authorities that the amount of available power lost in the waste of blast furnace gases varies from one and half to two million h.p. per hour.

The generation of blast furnace gases and the surplus available for power in any one instance, must be determined thus:—

To produce one ton (2000 lbs.) of pig iron requires a furnace charge of:—

One	3,400 lbs.
Coke	2,000 lbs.
Limestone	1,000 lbs.

Assuming for these factors a good average quality, we would have an analysis something like this:

Coke.—Good hard coke, 85 per cent. fixed carbon.

Limestone, 42 per cent. CO₂, containing 115 lb. of carbon per 1000; and for the pig iron producing an analysis approximating—

	Per cent.
Iron	93.50
Carbon	3.75
Silicon	1.50
Manganese	0.80
Phosphorus	0.40
Sulphur	0.05
Total	100.00

For the furnace gases, analysis by volume, with weights calculated upon the basis of 1000 cb. ft. at 62° F. would be:

CO ₂ 11.7	1000 cb. ft.=13,572 lbs. containing 3,70 lbs. carbon
CO 27.5	20,268 8.685
H 0.8	0.042
N 60.0	44,257
100.0	78,139 12.385

All the carbon charged into the furnace must appear in the pig iron produced, and in the furnace gases evolved. The furnace charge contained 1815 lb. of carbon, being 1700 lb. in the coke and 115 lb. in the limestone. The pig iron produced from the above charge contained 75 lb. of carbon as the analysis showed. Therefore each ton of pig iron produced, there went to the blast furnace 1740 lb. of carbon. From the weight of the gases evolved every 1000 cb. ft. contains 12,335 lb. of carbon. Therefore, for each ton of iron produced, there was evolved 141,000 cb. ft. of gas.

the analysis of the gas shows it to be 28.3 per cent. combustible, and to have a heating value of 90 B.T.U. per cb. ft., or a total heating value of 12,690,000 B.T.U. per ton of fuel.

The 2000 lb. of coke from which this heat was derived contained 24,650,000 B.T.U. Hence, we have for the thermic reaction of the reduction of the ore, sensible heat of slag and metal, radiation, &c., the difference between these two figures or 11,960,000, which is to say about one half of the heat potential contained in the gas, which was charged into the furnace, is contained in gas leaving the furnace. Furthermore, this heat potential is in the best possible condition for conversion to power; it is in the shape of a combustible gas, which is clean, and that without expensive or extensive apparatus, is admirably adapted for use in gas engines. If all the gas evolved is not available for use as power; if it must be used to heat the blast.

The analysis of the above gas shows 60.0 per cent. carbon (derived from the air) which is by volume 10.0 per cent. nitrogen. It follows that the amount of gas required to produce this gas must be in the proportion of 1.0 to 0.79. That is to say, for each 1000 cb. ft. of gas evolved, 700 cb. ft. of air were supplied. But we saw that for each ton of iron evolved 141,000 cb. ft. of gas. Therefore, for each ton of iron 107,160 cb. ft. of air must be supplied for each ton of iron 107,160

cb. ft. of air at 62° F. weigh 76 lb. Or the weight per ton of pig iron is 8144 lb. Taking the specific heat of air at 0.25, which is sufficiently high to account for the moisture, we have to heat the air through 107,160 × 0.25 = 2,679,000 B.T.U.

If the stoves are of low efficiency, and to be on the safe side and allow for losses in radiation and imperfect combustion, we assume an efficiency of but 50 per cent. This will double the above requirements, and give for heating the blast 4,072,000 B.T.U. With well designed stoves of sufficient capacity this should be more than enough.

For purposes other than heating the blast, there is therefore from one ton of iron produced 8,618,000 B.T.U. The original ton of coke contained 24,650,000 B.T.U. After heating the blast we have in the form of gas 16,038,000 B.T.U. remaining or 35.0 per cent. of the total heat value of the coke.

To determine the amount of power this heat will produce, we take the total heat available which is 8,618,000 B.T.U. by that required to produce a h.p. hour, say, 2,679,000 B.T.U., and we have more than 700 h.p. hours amount available in the gas evolved from the production of one ton of pig iron. This is a conservative estimate. All of this power is not available for general use. A part of this must be used for driving the blowing engines and other machinery about the blast furnace. The amount of power required for the production of a ton of pig iron may be estimated as follows:

For each ton of iron produced is 107,160 cb. ft. of air. If we consider a furnace having a capacity of 360 tons per day or 15 tons per hour, we would require engines of delivering 26,790 cb. ft. of air per minute.

To furnish this amount of air at 10 lb. pressure, and assuming 10 per cent. for friction load, there would be required 1200 h.p. In addition to this, there are other requirements of machinery to be driven which would make the total amount of power required to operate a furnace of this capacity approximately 1500 h.p., but the total available on this size furnace, as our figures indicate, is 107,160 h.p. per hour. Therefore, we have a surplus of 107,160 h.p. above all the requirements of the furnace of 900 h.p. Dividing this figure by the tonnage per hour of the 360-ton furnace, or by 15, we have, as the power producing capacity of the modern blast furnace using gas engines, 600 h.p. per hour per ton of iron produced per hour, or 25 h.p. per hour for every ton of iron produced per day.

There is within a reasonable degree of certainty the possibility of an available blast furnace gas supply for the use of the power plant, without interruption, no less than three blast furnaces can be considered sufficient to supply a power plant which is intended to produce power for the general market; for in any group of at least, one will at some time be out of blast for

relining and another may be stopped because of a shortage of raw materials, trade or labour conditions, accidents or trouble in operation or for other causes. With a group of three blast furnaces we are well assured that at least the surplus gas of one will always be available, and the essential condition of the power plant, that of uninterrupted service, will be afforded.

UTILISATION OF GAS FROM SUCTON PRODUCERS.

BY DR. OSKAR NAGEL.

Producer gas power plants are built for generating, out of a suitable fuel, a mixture of carbon monoxide and hydrogen called "Dawson Gas," which, if used in gas engines, allows an exceedingly advantageous utilisation of the fuel. Up to a few years ago producer gas has been made almost exclusively in so called pressure gas producers by evaporating water in a separate boiler and by leading the steam, mixed with air, by means of a steam blower or fan, through the glowing fuel whereby the steam is decomposed to hydrogen and the coal burned to carbon monoxide. This mixture of combustible gases is led through a scrubbing arrangement for removing the dust and tar, then through a gas holder for equalising the fluctuations of the pressure, and from here to the engine.

It is evident from this description that for generating gas by this method a boiler and a gas holder is required, which entails considerable cost of construction and attendance, and requires also a large floor space. Another disadvantage of the pressure system is, that it cannot be installed inside the city limits as it is not without danger on account of the possible leakage of gas. It was, therefore, an object of inventive engineers to supplant this pressure system by a safe and simpler construction in which no stock of gas is kept on hand, and in which no leakage can possibly occur. This has been fulfilled by means of the so-called suction gas producer, in which the pressure is supplanted by the suction of the moving gas engine. The use of a boiler and a gas holder is done away with in this system, as the engine is sucking just as much air and steam through the fuel as to generate the necessary amount of gas for the work required. This type has been very well developed on the Continent, and is especially to be recommended for units up to 250 h.p.

In a Suction Gas Producer plant the boiler is supplanted by an evaporator which, in small plants, is built frequently on the top of the producer in the form of a water-jacket, and in large plants close to the producer in the form of a tubular evaporator. This evaporator is generating the steam required by utilising the waste heat of the producer and of the gas, which is of considerable advantage as compared to the old system, the firing of a separate boiler being dispensed with. The heat of the gases, respectively of the producer, is entirely sufficient for furnishing the quantity of steam required for the generation of an effective power gas.

The utilisation of fuel in Suction Gas Producers is higher than in Pressure Producers, and is reaching 80 per cent. or more. The transformation of steam into hydrogen and the formation of carbon monoxide is taking place so quickly that the producer is always making the amount of gas required and is able to start suddenly from a low to a full load.

The advantages of a Suction Gas Producer are: automatic generation of the gas by the engine; highest and best utilisation of fuel; no boiler and no gas-holder is required; can be erected without danger in any convenient place; easy to start and to run; no soot, no smoke, no odour; no explosion possible; small floor space required.

A complete Suction Gas Producer Plant consists of a blower which up to 150 h.p. is driven by hand, a producer, an evaporator, an overflow water-pot, a scrubber, and a small equalising tank. In plants above 75 h.p. a sawdust scrubber is advantageously inserted behind the wet scrubber, and in plants where two or more engines are fed from the same producer a small gas-holder with automatic regulation is used.

The producer consists of an iron shell lined with fire bricks and provided with a suitable hopper. The grate area, according to the quality of fuel is 0.8 to 1 sq. ft. for every 10 h.p. The scrubber consists also of a sheet iron shell and is filled preferably with broken coke. If a good quality of fuel is used, the scrubber has to have a capacity of at least 1 cb. ft. for every h.p.

Before starting the engine the fuel in the producer has to be heated up by means of a blower until the gas is burning well on the test cock. When this point is reached the blower is stopped and the engine started in the usual way. The engine is now drawing by her own sucking action the necessary amount of air and steam through the fuel, and is producing her own power gas.

From the producer the gas is drawn through the scrubber and the equalising tank to the engine. The gas-making process continues as long as the engine is moving, but as soon as the engine is stopped the gas making is also stopped.

Anthracite, charcoal or coke can be used equally as well for generating gas in a Suction Gas Producer. It will take, according to the ash content, 1 to 1½ lb. of anthracite or charcoal, or 1½ to 1½ lb. of coke for developing 1 h.p. hour. With anthracite (pea) at 5 dols. per ton, 1 h.p. hour will cost about one quarter of a cent. This is about one-sixth the cost of illuminating gas power at a price of 75 cents per 1,000 cb. ft. of gas, or one-eighth the cost of gasoline power, figuring gasoline at 16 cents per gallon.

An ordinary illuminating gas engine has to undergo some slight changes before it can be used for producer gas. The compression has to be increased to at least 105 lb. and the ratio of gas to air has to be arranged 1:1½. The gas inlet has to be increased, and the air inlet decreased to the ratio above named.

COKE OVEN GAS.

BY C. G. ATWATER.

The forms of gas that have already been referred to, *viz.*, producer gas, Mond and blast furnace gas, are products of an operation involving partial combustion. In either case solid fuel is completely reduced to gaseous form, no carbon remaining in the residual ash if possible to extract it, this gasification being the main object of the operation in the first two instances, and incidental to the smelting of iron in the latter. The production of coke oven gas is distinguished from these operations in that it is the result of the destructive distillation of bituminous coal under the exclusion of air, and may be said to precede them in the cycle of operations. The object of such destructive distillation is primarily the production of coke, a raw material for both the blast furnace and gas producer. Incidental to this process is the evolution of the volatile portion of the coal in the form of gas; the gas, therefore, is a by-product. The production of gas by this method is exactly analogous to the distillation of coal in the ordinary gas retort, such as Murdoch used in 1798, in what we are told was the first method invented for the manufacture of illuminating gas, and which in modern form is still an integral part of a majority of existing illuminating gas works. In the retort, however, the gas is the principal product and the coke the by-product. Practically all that will be said in this paper of coke oven gas, as a source of power, would apply equally well to the use of illuminating gas, with the difference that the high cost of generating illuminating gas usually prohibits its use for power generation except in small units and under special circumstances. A short thermal calculation will show the truth of this and indicate approximately the limits with which city gas may be economically used for power generation.

Assuming 650 B.T.U. per cb. ft. as the average value of illuminating gas sold at 1.00 dol. per 1000 cb. ft., we have 650,000 B.T.U. for 1.00 dol., or 1,000,000 B.T.U. cost 1.54 dols. Assuming coal at 3.00 dols. per ton (of 2000 lb.) having 13,000 B.T.U. per lb., a million B.T.U. costs but 8.6 cents. This great discrepancy in cost is reconciled to some extent by the greater efficiency of the gas engine, which delivers, roughly, a brake h.p. per hour from

20 cb. ft. of gas, costing 2 cents., whereas the steam boiler and engine combination requires about 3 lb. of coal per hour per h.p. in moderate sizes, at a cost of 0.9 cent. This would be increased somewhat by the cost of coal handling and labour in the boiler house. It is, therefore, clear that illuminating gas at 1.00 dol. per 1000 ft. has a wide field as a source of power, but it is also apparent that at a cost of, say, one-fourth or one-fifth the value assumed above, it would become a prominent factor.

In order to make clear the analogy between coal, made from the gas retort and from the by-product coke oven, the following analyses are submitted as typical

	Coke Oven Gas.	Retort C Gas.
	Per cent.	Per cent.
Methane	39.6	36.02
Other hydrocarbons	5.4	4.75
Hydrogen	37.6	47.04
Carbon monoxide	5.8	8.04
Carbon dioxide	3.5	1.60
Oxygen	0.4	0.39
Nitrogen	7.7	2.16
B.T.U.	693	693

The coke oven gas in this instance is that known as the rich portion, and is given off during the first part of the coking time, this method of operation being known as the division or fractioning of the gases. In this the more valuable portion of the gas is reserved for illuminating or power purposes, the remainder serving to the coking ovens. As coke oven gas for illuminating is usually treated in this way, it is proper to select a fraction of the coke oven gas for comparison with the illuminating from retorts. The principal characteristic of the fractionated coke oven gas is that the methane is approximately the same percentage or a little higher than the hydrogen. This is an advantage in gas engine work, as it diminishes the chance of pre-ignition under compression in the engine cylinder, although in neither case is this liable to create trouble. If there was no probability that any portion of the coke oven gas would be used for illuminating purposes, the fractioning process might be eliminated, and a single condensation system installed in place of a double one. Under these conditions the surplus gas available for gas-engine use would be the average of the whole product, and might be represented by the following average analysis:—

Methane, 33.9 per cent.; other hydrocarbons, 8.1; hydrogen, 44.4; carbon monoxide, 6.2; carbon dioxide, 2.9; oxygen, 0.3; nitrogen, 8.5 per cent. B.T.U.: 20.

In considering the by-product oven as a source of power, the efficiency of the process should be determined. This is shown in the following table of the heat balance, giving the British thermal units originally contained in the coal, and their distribution among the various products recovered:—

Distribution of Heat Units in Coal.

100 lb. of dry Coal Yield.	B.T.U. per lb.	Total Calorific power B.T.U.	Per cent. of calorific power of dry coal.
71.13 lb. of coke	12,645	899,456	1
3.38 lb. of tar	12,219	51,410	1
229 cb. ft. of surplus gas ...	686	157,504	1
234 cb. ft. of heating gas ...	567	182,835	1
Ammonia liquor, sulphur in purifier and loss	—	2,496	2
Total=100 lbs. dry coal ...	—	1,243,700	100

These figures are taken from Dr. Schniewind's paper, entitled "The Production of Illuminating Gas from Coke Ovens." From this table it is evident that the percentage of the total heat required for the conversion is 10.7-10.9 per cent. of the whole heat available. This efficiency of practically 11 per cent., and compares favorably

operation of the by-product portion of the producer plant, a coal high in percentage of nitrogen must be employed. After a careful ultimate analysis of the slack used in the Mond producer in England, we were fortunate in finding one corresponding closely to it in the Hocking Valley coal fields. It is a coal approaching a lignite in composition, having 6 to 7 per cent. of water of constitution, and a high percentage of oxygen, and is especially desirable because of a high percentage of nitrogen. The analysis of the English coal and the Hocking Valley are as follows:—

	Hocking Valley Nut. Coal.	English Producer Coal.
	Per cent.	Per cent.
Moisture chemically combined	7.84	6.85
Volatile matter	27.95	33.14
Fixed carbon	50.75	48.93
Ash	13.46	11.10
Sulphur	1.50	1.68
Nitrogen	1.45	1.35

The relation of the hydrogen to the oxygen in the coal, which is an important factor in the clinkering and the yield of ammonia and tar, is as follows:—

	Hydrogen.	Oxygen.	Available Hydrogen.
	Per cent.	Per cent.	Per cent.
English coal	3.90	12.08	2.32
Hocking Valley	4.65	10.86	3.26

The Mond gas at Detroit is somewhat different from that obtained in England, as the following comparison shows:—

	Mond Gas.	
	Detroit.	England.
	Per cent.	Per cent.
Carbon dioxide	14.6	16.5
Oxygen	0.5	—
Carbon monoxide	10.3	11.0
Methane	5.3	2.0
Hydrogen	23.5	27.5
Nitrogen	55.8	43.0
Total combustible	39.1	40.5
Gross B.T.U. per cb. ft.	163.5	145.5
Net B.T.U. per cb. ft.	146.6	129.7

The yield of ammonia amounts to 70 to 75 lb. of sulphate per long ton of coal. Tar amounting to 55 to 65 lb. per ton of coal is also recovered; this is much lighter in gravity than the ordinary coal tar and has little value except as a fuel and as such is worth about 1s. per gallon.

Taylor Producer.

I might say a few words in addition to what has already been stated about ordinary producer gas.

For the production of gas to be used under drying furnaces we have at the works of the Solvay Process Co. at Syracuse, 30 Taylor Producers, which gasify 134 tons of anthracite buckwheat coal per day. The air is introduced by means of live steam injector, and the coal for the steam used is about 10 per cent. of that gasified. These producers are not supplied with automatic and continuous feed. The analysis of gas advertised as attainable by the promoter of the Taylor producer is seldom obtained in practice. The temperature of the producer chamber above the fuel bed is so high, due to unevenly covered surface of the bed and the holes through the bed, that the water is dissociated, hydrogen formed and the percentage of carbonic acid gas increased.

Temperatures taken with electrical pyrometers at various points in the producer were as follows:—

	Number of Producer.			
	1	3	5	7
	°C.	°C.	°C.	°C.
Temp. at top of fuel	950	955	965	976
2 ins. above surface	900	910	910	905
1 ft. above surface	650	650	660	650
2 ft. above surface at outlet	600	600	605	595

The analyses of producer gas, as made at Syracuse and that advertised by Mr. Taylor, are:—

	Syracuse.	Mr. Taylor
	Per cent.	Per cent.
Carbon dioxide	8.4	4.5
Oxygen	0.2	0.6
Carbon monoxide	22.7	25.5
Methane	1.0	1.0
Hydrogen	16.2	12.0
Nitrogen	51.5	56.4
B.T.U. per cb. ft.—Gross	136.4	131.7
B.T.U. per cb. ft.—Net	127.5	123.8

Theoretical Considerations.

I wish to call attention to a few theoretical considerations which have a bearing upon the efficiency of the various gases in the gas engine. The following table gives the analysis of the gases, their heat value, theoretical amount of air required for combustion and corresponding pressure and the relative volume of gas before and after combustion under the same conditions of temperature. The sample of coke oven gas represents that which is available during the first eight hours of the coking process.

Composition: Per Cent. by Volume.

By gross is meant that the temperature is brought to the same point before and after combustion (figured for 100° C.) and that the water formed is condensed.

By net is meant that the temperature is brought to the same point before and after combustion (figured for 100° C.) and that the water is not condensed.

Calculations based on Thompson's results "Thermomische Untersuchungen."

The practical value of efficiency of a fuel gas within the cylinder of a gas engine is ordinarily considered to be in direct proportion to the heat units of that gas, but this is not strictly true; fuel gases of the various kinds have different percentages of a number of different gases each having its own individual qualities which in the explosion and the transference of thermal energy into mechanical. For instance, there is a difference in the inflammation temperature of the various constituents of the gases: hydrogen ignites at 550° C., carbon monoxide at 655° C., methane at 656° C. It is said that a gas containing a percentage of hydrogen is particularly liable to pre-

ignition. While we know the temperature of the gases singly, nothing is known concerning the temperature of a mixture of these gases at various conditions at atmospheric and other pressures. Experiments in this direction would doubtless be of great assistance to designers of gas engines.

Then there is the question of propagation of flame and its relation to the economical production of power in the gas engine. The normal propagation of flames (according to Berthelot) of hydrogen, is 4.3 meters per second, methane 0.62 meters, and carbon monoxide 2.0 meters per second.

The experiments made at the Institute of Technology in Boston give the rapidity of explosion of hydrogen with the theoretical quantity of air as more than 10 times that of illuminating gas. Berthelot says when two combustible gases, such as hydrogen and carbon monoxide are burned in oxygen, the rate is by no means the mean of that of the two gases. They appear to burn separately each with its own rapidity. Further, water, one of the products of explosion, dissociates at 874—900° C., and may this not take place at the expense of thermal energy and may it not happen that there should be sufficient cooling of the cylinder to prevent recombination and giving up of that heat before the exhaust opens? The dissociation of carbon dioxide begins at 1300° C., but, of course, this is never reached. All of these considerations doubtless have some bearing on the efficiency of the gas for power development.

Mean Pressure Efficiency and Calorific Values.

From the Technology measurements of the mean pressures obtained during the first 0.2 second after explosion, using all proportions of air to gas, it appears that, in the case of water gas, the best efficiency results when using that quantity of air which gives a theoretical maximum pressure of about 8.4 atmos. (124 lb. per sq. in.). Using this quantity of air with the above gases (except the blast furnace gas) the following results are obtained:—

	Syracuse Producer.	Detroit Producer.	Coke Oven.	Blast Furnace.	Natural Pitts.	Natural Ohio.
Vol. of air per 1 vol. gas	1.09	1.50	8.93	0.65	12.4	13.5
Theoretical temperature, °C.	2560	2435	2358	2227	2313	2302
Theoretical pressure (max.) atm.	8.4	8.4	8.4	7.5	8.4	8.4
Theoretical pressure, lb. per sq. in.	124	124	124	110	124	124
Vol. of mean pressure efficiency equal vol. of gas ..	1	1.20	4.76	0.70	6.41	6.96
Vol. of calorific values of equal vol. of gas ..	1	1.18	4.56	0.70	6.15	6.70

In the following charts, one, of some explosion experiments made with the Mond gas at Detroit under direction of Mr. A. F. Shattuck, and the other of some explosions of illuminating gas of 721 B.T.U. (gross) mixed with various percentages of air, made by a student at the

Institute of Technology in Boston, it will be observed that the maximum pressure obtained is about one-half the theoretical; further, that this maximum pressure is obtained when 80 to 85 per cent. of the theoretical air necessary for combustion is used.

FIG. 1.

FIG. 2.

Coke Oven Gas.

We now come to the consideration of retort coke oven gas for gas engines. While it is true that a coke oven gas is similar in analysis to coal gas, or illuminating gas made in the well-known gas retort, the composition of the coke oven gas is within the control of the operator; the ovens may be so regulated that the hydrogen may be low or high in percentage; that the carbon dioxide may be reduced to a minimum or almost eliminated, or it may be of such a percentage as to materially deteriorate the gas for illuminating or power. This is made possible because of the large size of the charge of coal in the by-product oven; the possibility of regulating the temperature of coking and the time of coking. In coal gas manufacture, a small retort of 300 or 400 lb. capacity, fired with coke and coked in five or six hours, is used. In the by-product oven, eight or nine tons of coal are coked in a space approximately 30 ft. long, 8 ft. high, and 17 in. wide, during a period of 22 to 24 hours; by manipulating properly the valves between the oven and the hydraulic main, turning the gas first into one and then into the other main, the quality of the gas may be regulated to a nicety; by the proper regulation of the supply of the gas to the oven for the coking process and by the regulation of the temperature of the flues by electrical pyrometers and Seger cones, the temperature of the distillation within the oven may be maintained at any desired degree. We may thus obtain by proper manipulation gas of varied composition, as is shown by the following analyses:—

Analysis of Gas.

Nine hundred thousand cu. ft. per day of enriched gas of 18 candle power were delivered during the year 1905 from the Semet-Solvay Co. plant of 40 ovens at Chester, Pa., to the Chester Gas Co., which, in turn, dealt it out to consumers for illuminating, gas engines, and fuel purposes.

Gas of the quality shown in the table of analyses, containing a high percentage of benzene and methane, and low percentage of hydrogen, is formed during the early stage of the coking process. The gas formed in the latter part is practically devoid of benzene and ethylene, the illuminants, and high in percentage of hydrogen. As it is desirable for power purposes to have a gas of minimum hydrogen to avoid possibility of pre-ignition, gas of quality represented by the first analysis is the best.

The following chart shows how the B.T.U. falls off the tenth hour, and likewise how the per cent. of methane diminishes and the hydrogen increases.

The distillation process proceeds from the top downward, and the heat reaches the centre of the mass of coal very slowly.

Experiments were made and temperatures taken by electrical pyrometer every 15 minutes from several locations in the oven and also above the mass of coal; here the lowest temperature was about 720° C. The temperature of the heating flues, three in number, horizontally placed was 1050—1150° C.

Quality of Gas Dependent on Composition of Coal and Time of Oven.

The quality of the gas is not only dependent upon the heat of the oven, but also very largely upon the quality of the coal. This is well known and recognised when considering the Pennsylvania bituminous coking and coals and their relation to heavy hydrocarbons or illuminants in the gas, but that different coals when coked in tight ovens, which exclude the air give varying percentages of carbon dioxide, is not well known. Some coals of the Illinois and Indiana region and the Far West, more or less of a lignitic nature, give a gas containing as much as 8 per cent. of carbon dioxide gas, whereas a Pennsylvania coal under the same oven conditions would give only 1 to 2 per cent. This naturally would cut down the B.T.U. considerably, and reduce largely the efficiency in the

FIG. 3.

gine. The reason for this high per cent. of CO₂ the gas is the high percentage of oxygen in the coal. Analysis of an Illinois coal, Big Muddy, for instance, shows 12 per cent. oxygen. In it there is a large excess of oxygen over that required to combine with hydrogen in the coal, and this excess combines with carbon to form an abnormally high percentage of carbon monoxide and dioxide.

Coke Oven Gas at Detroit and Milwaukee.

It will be observed from the following table that the gas at Detroit and Milwaukee is considerably richer in heat than that previously described as being made at Chester. The increase in energy for gas engines per unit volume is due to the greater amount of benzene, toluene and naphthalene it contains. The process by which this is accomplished may be described as follows:—As before stated, the gas evolved during the early part of the coking period is richest in heat-giving constituents; hence this rich gas, that evolved during the first 7 or 8 hours, is separated from that made during the remaining 16 hours, and afterwards further enriched by means of benzene and its homologues taken from the lean gas. The Semet-Solvay coke ovens, 120 at Detroit and 80 at Milwaukee, during the year 1904 have delivered to the gas companies of these cities gas of about 675 B.T.U. (gross) of 19 to 21 candle power, at the rate of 2,700,000 cu. ft. 1,900,000 cu. ft. per day.

Objection to Coke Oven Gas on Account of Sulphur.

Objection to the use of coke oven gas, without previous treatment to remove the sulphur, cannot be invariably maintained. Our own experience at Syracuse for several years with a 125 h.p. Westinghouse engine developing 85 B.H.P.—90 lb. pressure—on coke oven gas of 150 B.T.U. (net) (28 cu. ft. gas per B.H.P.), made from a coal containing 1.4 per cent., is that no serious corrosion has taken place due to sulphuretted hydrogen or sulphuric acid.

If, however, water were mixed with the lubricating oil in the crank case, enough sulphuric acid would be soon absorbed to cause attack on the metal.

Of twenty-two gas engine installations in Germany, of a total of 13,000 h.p., working on coke oven gas, 11 or 50 per cent. do not find it necessary to purify the gas. The others use bog-ore or saw dust. With efficient tar extractors and ammonia washers, tar and dust are readily removed. One of these German installations was using a gas with 0.2 per cent. sulphur without injurious effect on the iron.

Pre-Ignition.

Pre-ignition or explosion before the completion of the compression is said to more often happen with coke oven than with other fuel gases, like producer and natural gas, and the reason given for it is the high percentage of hydrogen. Authorities vary as to the cause of pre-ignition. If pre-ignition is chargeable to high percentage of hydrogen, coke oven gas is no more liable to pre-ignition than Mond producer, or ordinary producer gas; unquestionably we must consider the percentage of hydrogen in the explosive mixture. By the following it will be seen that the coke oven gas, used in the above table of gases, when mixed with that amount of air which gives the maximum efficiency in the engine, contains less hydrogen than the proper mixture of producer gas and air.

7.5 Atmos.

	Syracuse Producer.	Detroit Producer.	Coke Oven.	Natural Pittsburg.	Natural Ohio.	Blast Furnace.
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Hydrogen	7.77	8.16	4.60	1.50	0.13	0.00
Carbon monoxide	10.88	3.00	0.42	0.08	0.04	16.67
Hydrogen	0.48	3.08	3.70	5.38	6.37	—
Hydrogen	—	—	0.48	0.05	0.01	—
Carbon dioxide	—	—	0.10	C ₂ H ₆ =0.27	—	—
Carbon dioxide	4.03	6.04	0.18	0.06	0.01	7.09
Hydrogen	0.09	0.44	0.02	0.08	0.03	—
Hydrogen	24.60	19.28	0.58	—	0.26	36.85
Hydrogen	52.06	60.00	89.92	92.58	93.15	39.39

Pre-ignition is not common with small engines up to 50 h.p., and with large engines is no more frequent with coke oven gas than with other fuels. Of eight managers of plants using coke oven gas in engines up to 750 h.p., whose opinion was asked concerning pre-ignition, two stated that they had had some pre-ignition, and six had never been troubled with it, though the hydrogen ran as high as 50 per cent. in some instances. One of the managers who had trouble said that he had overcome it by trying the compression in inverse proportion to the percentage of the gas mixture. One of the greatest authorities in England, who has tested many engines of various types and worked them on various kinds of gas, in writing to our company stated that he had used coke oven gas in a 40 h.p., 107 lb. pressure, and 140 h.p., 95 lbs. compression engine without being troubled with pre-ignition, that he had

worked a Vogt engine to a pressure of 200 lb. on coal gas, practically the same as coke oven gas without trouble, and many others from 100 to 650 h.p. He further says, "that probably when a gas contains more than 30 per cent. of hydrogen the additional hydrogen has but little effect upon the question of pre-ignition." He further states, "in probability the effect of free hydrogen in producing pre-ignition is not the question of temperature at which free hydrogen combines with the oxygen of the air present, but has to do with the effect of free hydrogen on the iron of the cylinder and possibly on the layers of partly burned oil."

I believe coke oven gas to be the power gas of the future, in places where it is impossible to get blast furnace gas or natural gas, on account of its high calorific value, freedom from dirt and tar, and its adaptability to pumping great distances under pressure in comparatively small pipes.

DISCUSSION.

Dr. F. SCHNIEWIND remarked that New York City consumed, in 1903, approximately 6,000,000 tons of anthracite and 3,000,000 tons of bituminous coal. The inevitable rise in the price of anthracite, keeping pace with the depletion of the mines and the universal objection to the further introduction of bituminous coal, because of its smoky nature, would, sooner or later, result in the use of coke as a substitute for other forms of solid fuel. The surplus gas from the coke ovens, supplying the coke to the city, could be used in gas engines for the generation of power, and would supply a large amount of that now required in the traffic and manufactures of the city. In the great cities of the west, where only bituminous coal was used, the smoke nuisance had already become a serious matter. The only relief for them appeared to be in the use of smokeless fuel, such as coke. The soft coal now used could be transformed into this shape in a by-product oven, the smoke-forming elements being recovered in the form of gas for power or illuminating purposes, and a cleaner and more economical fuel would be the result.

An advantage would be gained not only in regard to the solid fuel, but to the gaseous as well, as the coal gas produced from the coke ovens was far superior to producer or blue water gas for distribution purposes, and better adapted to gas engine use than the water gas, because of its low percentage of hydrogen. It was also coming to be generally recognised that for continuous production in large quantities coal gas was cheaper than carburetted water gas. The introduction of the by-product coke oven as a source of supply for fuel, light and power, seems, therefore, to be a necessary and inevitable accompaniment of our progress in civilisation.

Dr. F. MEYER said that the plant where he gained his experience with gas as a source of power was built 25 years ago. As far as he knew, it was the first zinc plant which entirely relied on gas as a power. The gas used was illuminating gas, made in a plant owned by the smelter. Later on, when steam was needed for the manufacture of liquid sulphurous acid, boiler plant was added, which also furnished the power for the compressors and the pumps used in the acid plant. The compressors used in the sulphuric acid plant, which worked according to a contact process, were also steam-driven; the rest of the machinery, *e.g.*, crushers and rolls, clay-grinding and retort-making machinery, electric light plant, shops, &c., were operated by gas engines, varying from 1 h.p. to 50 h.p.

Mr. Atwater mentioned that a h.p. hour generated from city gas cost about 2 cents. In their case, where the gas was generated in their own plant, the cost was far less; for example, with coal costing about 2.50 dol. per metric ton, a cb. m. of gas cost 5 pf. The coal was not a good gas coal, as it only developed about 30 cb. m. of gas per 100 kilos. of coal. That part of the coke which was not used for heating the retorts was sold, and also the gas water and the tar. After deducting the returns from these sales from the gross cost, the net cost of one cb. m. of gas was almost exactly 3 pf. Taking three-quarters of a cb. m. for 1 h.p. hour, the cost of 1 h.p. hour worked out at 2½ pf., equal to a little over half a cent or only quarter of the price mentioned by Mr. Atwater. This cost would, of course, be still reduced if producer gas or water gas were used instead of illuminating gas.

One thing must, however, be said in favour of the steam engine, compared with the gas engine—*i.e.*, the greater reliability of the former engine. The cost of keeping the gas engine in repair was large, and a staff of good machinists and engineers was required to keep it in proper condition.

In large works where the gas engines were scattered about there might also occur heavy losses from leaking pipes, if these were buried in the ground, as usually the case in older installations, but, as a whole, gas would in almost every case be a cheaper source of power than steam.

Mr. E. A. UEHLING said that every blast furnace could be considered as a gigantic gas producer, and the blast furnace gas, although low in calorific power, was never-

theless admirably adapted for direct utilisation in the gas-engine. Because of its susceptibility to high compression without danger of pre-ignition, it was better adapted for engines of large units than almost any other gas.

In his pamphlet, "The Blast Furnace as a Power Plant" he had endeavoured to calculate on a conservative scientific basis, the amount of power that should be available over and above the furnace requirement. The results showed that, with a fuel consumption 2000 lb. of coke per gross ton of iron, there should remain a surplus of over 800 h.p. per ton of iron produced per hour. Since in America the production of pig iron is now above 20,000,000 tons per annum, or 2283 tons per hour, over 1,800,000 h.p. were generated which could be made available, if every furnace in the country were equipped for the full utilisation of the gas produced. While it might be seriously questioned that that amount of power could ever be realised, the fact none the less remained that it is still practically all of it wasted.

Most of those who had written on that subject gave a much lower figure than the above, basing it on a reduced amount of power available on the irregularity of the furnace running, and upon a much higher consumption of gas for heating the blast. His own opinion was that when the value of the blast furnace as a source of power became fully recognised, it would tend to improve the blast furnace practice to an extent that would make irregularities very much less frequent, and that, with properly constructed hot-blast stoves running on purified gas, the consumption of gas for heating the blast would be very materially reduced.

The manner in which blast furnace gas was utilised was most irrational. With few exceptions, the methods employed for purifying blast furnace gas were most crude and ineffective. Even where washing was resorted to it was generally done very imperfectly, although the gas was deprived of a considerable amount of solid matter, it was generally saturated with steam, and consequently the beneficial effect of relieving the gas of dust was over-balanced by contamination with water vapour. For that reason, both boilers and especially hot-blast stoves, used a much larger amount of gas than they should. There was no hot blast stove in operation at the present time, the heating surface of which could not be doubled or possibly trebled if perfectly purified gas were available.

When it is considered that the first blast furnace gas engine of large power (500 h.p.) shown in public was exhibited by the Cockerill Company at Paris in 1860, the progress made in Continental Europe, especially in Germany, was marvellous, there being upwards of 30,000 h.p. in use and under construction, and there was hardly an iron works of considerable size that had not installed one or more of these engines; whereas in America there was but one steel company that had made any serious attempt towards the utilisation of the blast furnace gas for power direct, namely, the Lackawanna Steel Company, who had ordered 40,000 h.p. of blast furnace gas engines, probably one-half of which were running.

Dr. J. D. PENNOCK, in reply to Dr. Schniewind's question as to how much steam was used in blowing and producing and if it were not a fact that the steam necessarily was a considerable item, said he was unable to give the exact figure, but that the steam was a very considerable item there was no doubt. In fact, the steam for blowing the Mond producer cost about as much as the labour for operating. The tendency of the works was to use a large amount to reduce the clinker; the tendency of the manager was also to use a large amount, for thereby he increased the yield of ammonia.

Scottish Section.

THE IDENTITY OF THE HYDROLYTIC PRODUCTS OF STARCHES OF VARIOUS ORIGINS.

BY JOHN S. FORD AND JOHN M. GUTHRIE.

investigations of the hydrolysis of starch by malt extract, potato starch has in general been employed, no doubt to the relative ease with which it can be obtained and purified. In an early paper on starch hydrolysis, C. O'Sullivan (*Jour. Chem. Soc.*, 1876, 2, 111), stated, though his experiments were carried out only with potato starch, he satisfied himself that other starches, as rice, wheat, maize, &c., gave identical results, and admit that starch is a chemical entity, it seems only reasonable to expect that the origin of the substance should not affect its chemical composition, even though it may be associated with polymorphic granules which in the crude state contain impurities differing in nature and amount. Even if freed from these impurities we would not expect the various solid starches to be dissolved or attacked at equal rates by malt extract, but when reduced to homogeneous solutions by treatment with boiling water, and so brought to practically similar physical state, it might be expected that malt extract under like conditions would give similar transformation products whatever source of starch was obtained from. This view has received general acceptance (though probably the statement of O'Sullivan (*loc. cit.*) has been lost sight of) until recently, and the results of the experimental investigations with potato starch have received practical application in the brewing industry and elsewhere, in connection with the hydrolysis of other starches. We do not propose to enter into the question of how far the relationship holds, but it is not held, between the hydrolysis of starch pastes, and that of the starch of germinated grain in the laboratory under brewery conditions. The object of this paper is to discuss certain recent statements as to the non-identity of the products of hydrolysis of starches of various origins under laboratory conditions.

O'Sullivan (*Jour. Chem. Soc.*, 1904, 85, 616) published a series of experiments, made with seven different preparations, and concludes from these, that potato starch behaves differently to the other starches, and therefore that the products of the hydrolysis of other starches may be inferred from the results obtained with potato starch. Ling (*Fed. Inst. Brew.*, 1903, 9, 452) arrived at a similar conclusion. In a communication by one of us (*1904, 414*) it was stated that rice, barley, maize, potato and arrowroot starch pastes were found to be identical as regards their products of hydrolysis when prepared with malt extract under like conditions. Undoubtedly work with other starches had confirmed the view that the origin of the starch was without effect on the nature of the products of hydrolysis, provided the starches were sufficiently purified and free from substances which inhibit amylolytic action. The starches were prepared by ourselves directly from the plant material with the exception of the arrowroots, which were obtained commercially and subjected to purification in a special manner. The crude starches were purified by treatment with 0.2 per cent. caustic soda and hydrochloric acid, washed with distilled water, and extracted with ether, and then further at 25°–30° C. It is more probable that starches so obtained contain varying amounts of starch cellulose* which may cause slight differences in the hydrolytic products. Our methods of purification are at present, however, not sufficiently refined to note such differences with any degree of certainty. With regard to the general purity of such preparations of potato starch we used as a standard gave the following results:—

Ash	0.17 per cent.
N. as albs.	0.05 per cent.

Its reaction was neutral to rosolic acid and acid to phthaline, this latter reaction being due to the presence of acid phosphates.

In Table I. we record the results obtained. In each experiment the starch (5 grms. dry) was reduced to a fine powder, cooled to 65°, and converted with 25 c.c.s. of malt extract (=10 grms. malt) which had previously been heated for 10–15 minutes at 65°.

The conversions were made to definite volumes, and the sp. gr., optical rotation, and copper-reducing power, observed. Similar values were obtained for the malt extract used. The copper reduction was not determined in all cases. Our experience has convinced us of the validity of "the law of relationship" propounded by Brown, Morris and Millar (*J. Chem. Soc.*, 1897, 71, 115), hence determinations of the solids and their optical rotation is all that is necessary. The copper reductions obtained were in good agreement with the theoretical values. We also made several experiments using precipitated diastase (of malt) as the hydrolytic agent, the results were similar to those obtained with malt extract. In the paper by one of us already referred to, the influence of metallic and other impurities on amylolytic action was fully discussed, and in a recent paper on malt analysis (*Jour. Inst. Brew.*, 1905, 11, 206) we pointed out that solid starch readily absorbs from solution substances which may interfere with normal hydrolysis. Our experience of this has been so repeatedly confirmed that we have no hesitation in saying that where other workers have found apparent variations in the hydrolytic products of different starch preparations under like conditions of hydrolysis, these differences are due to impurities in the starches in question, and not to a difference in the starch *qua* starch.

In view of the contradictory statements of J. O'Sullivan (*loc. cit.*) and ourselves, we communicated with Mr. O'Sullivan, suggesting an exchange of samples. Mr. O'Sullivan kindly sent us a specimen (A 4) of his potato starch, which, on comparison with our own standard No. 27 in the usual manner, gave the following results:—

	A 4.	No. 27	
Hydrolysis with malt extract at 60° ..	158.7	153.3	(a)
Hydrolysis with precipitated diastase at 60° ..	167.8	143.8	3.93
5.0 grms. starch + 0.2 gm. (a) diastase ..			

A further examination of the A 4 starch showed that it contained copper to the extent of 0.035 per cent. Our former experience of the influence of traces of copper on amylolytic action indicated that this amount of copper might be sufficient to account for the difference in hydrolysis of the two specimens. To obtain confirmatory evidence, a portion of No. 27 starch was shaken with a very dilute solution of copper sulphate, then thoroughly washed with distilled water and dried as usual. The reaction to indicators was the same as that of the starch before this treatment. This "copper starch," which contained 0.06 per cent. of copper, was added to a quantity of No. 27 so as to give a mixture containing 0.035 per cent. A comparison* was then made between this mixture and No. 27, as under:—

	No. 27.	No. 27 + 0.035% Cu.	
Hydrolysis with malt extract at 60° ..	153.4	160.5	(a)
Hydrolysis with precipitated diastase at 60° ..	167.8	159.2	3.93
5.0 grms. starch + 0.2 gm. (b) diastase ..			

This amount of copper (0.035 per cent.) is thus sufficient to bring about a marked reduction in the maltose formation, and hence in the nature of the hydrolytic products.

* The results in this experiment are not directly comparable with those above, being obtained some months later with other malt extract and diastase preparations. Owing to the small quantity of "A 4" at our disposal we were unable to make direct comparison between it and our "27 + Cu" under like conditions. The recurrence of similar figures in the two sets of experiments is accidental.

the accompanying illustration of the apparatus used, 32 oz. flask fitted with a 100 c.c. pipette; B is a safety C is a tube for removing water from the steam flowing the temperature of the latter to be observed; a tube in which condensed water may gather; E is a r joint fitted with a spring clip, connecting to a leading to a small beaker placed beneath; F is a r joint connecting the tube which leads the steam to a large test-tube G; H, H, H, are thermometers; and a tube for carrying off surplus steam. When the apparatus is in use C is wrapped round with a piece of wool, while the tube G is inserted into a cylinder lined with the same insulating material. The water flask A is boiled, the clip at E being left open until the apparatus is warmed up and steam issues freely. As steam accumulates in the tube D during the course of the experiment it may be discharged by opening the clip, forcing a solution in the tube G, and allowing the steam to pass through it, the temperature will rise steadily until it is reached at which it will remain for a time, and then gradually fall. If the steam be allowed to escape at once by opening the clip at E, and the tube G removed with its fittings in place, and heated to boiling over a lamp, the temperature reached will, as a rule, be a little higher than that which was attained by the use of the steam. In many cases, by having a quantity of powdered salt present so as to keep the solution in a saturated state, the b. pt. of a saturated solution, the temperature very near that point, may be readily reached and maintained. Under the conditions of my experiments the steam passing through the tube C has a temperature of 99.0° which rises to 99.2 or 99.3° when added to the hydrostatic pressure in the tube G. The steam escaping from G has a temperature of 99.0°. Some of the solutions are placed in the solutions for the purpose of producing steady boiling.

The following table the temperatures attained by non-saturated solutions, when heated by steam under the above conditions, are stated, as also the temperatures at which the same solutions boil when heated over a lamp:—

Non-saturated Solutions.

	Boiling Temperatures.	
	With Steam.	Over Lamp.
phosphate	103.0	103.5
carbonate	104.2	104.5
nitrate	105.5	106.5
am chloride	111.5	112.5
acetate	112.5	114.0
nitrate	117.5	118.5
n acetate	147.0	152.0
chloride	149.2	150.0
am nitrate	155.0	156.0
am nitrate (stronger)	163.0	164.0

It will be noticed that in all cases the temperature by heating over the flame is somewhat higher than that attained by means of steam. The temperatures, however, by the various solutions depend, of course, on the concentrations. With a strong solution of ammonium chloride at atmospheric pressure is competent to reach a temperature to 163°. In carrying out this experiment steam was passed direct into moist ammonium chloride and the temperature mentioned was quickly reached in spite of the fact that there is a considerable effect when this salt is dissolved.

Saturated solutions, as I have before mentioned, may be heated in the same way, by having a quantity of the salt present in the hot solution. In the next section I give the temperatures attained by the use of saturated solutions of a number of salts, and, for comparison, the b. pt. of the same solutions as published by heating over the lamp and also as published in Watts' Dictionary of Chemistry, and elsewhere.

Saturated Solutions.

Boiling Temperature.

With Steam Over Lamp. Boiling Points*

Potassium chlorate..	103.3	103.5	104.2
Zinc sulphate	103.5	104.8	104.4
Sodium carbonate ..	105.2	105.5	104.6
Potassium chloride ..	108.0	108.2	108.3
Sodium chloride	108.0	108.2	108.3
Potassium nitrate ..	114.0	115.0	115.0
Ammonium chloride ..	114.0	115.0	114.2

* The b. pt. of a saturated solution of zinc sulphate is given by Griffiths and is given in Comey's Dictionary of Chemical Solubilities, p. 459, that of potassium chloride is the figure found by Legrand and quoted in Clarke's Rules, Tables and Data, p. 389; all the others are given on the authority of Legrand in Watts' Dictionary of Chemistry, vol. iii., p. 89.

As is the case with non-saturated solutions the temperatures reached by the use of steam are somewhat lower than those obtained by boiling over the lamp, while the latter figures are sometimes higher and sometimes lower than the published b. pts. for saturated solutions of the salts experimented with. In this connection it should be explained that the salts used by me were the ordinary commercial ones sold by reputable dealers for laboratory use.

When dealing with very soluble substances such as calcium chloride, the solubility of the salt prevents saturation being reached. When steam is blown into granular calcium chloride, a solution is formed having a temperature of 149.2°, while by heating over the flame this solution boils at 159°. If a saturated solution of the same salt is prepared by stirring powdered calcium chloride into the above solution kept boiling over a flame, the pasty mass formed boils at 175°. If now the tube containing the hot saturated solution be quickly placed in the lagged holder, and steam passed in, the solution does not remain at the same temperature, but steadily cools. If the steam be now turned off, the contents of the tube allowed to cool somewhat, and steam again turned on, the temperature rises to a few degrees below the point at which it stood in the first instance. With ammonium chloride, treated in the same manner, the steam merely passes through and does not form a solution, consequently the contents of the tube do not rise above the temperature of the steam itself. On adding a little water, a saturated solution is formed which becomes heated to a temperature of 114.0°, or only 0.2 less than the b. pt. for a saturated solution of this salt given in Watts' Dictionary, while on heating over the lamp it boils at 115.0°, which is 0.8° higher. A saturated solution of zinc chloride is stated in Watts' Dictionary to boil at 172°. With the apparatus described it is possible, by starting with the powdered salt into which steam is passed direct, to heat a saturated solution in which is suspended an excess of the salt, as high as 177°. Doubtless in this case the heating effect is aided by the heat of solution of the zinc chloride.

The theoretical explanation of the results of the experiments above described is comparatively simple. When water is heated the pressure exerted by its vapour increases until, on the attainment of b. pt., it equals that of the atmosphere. The boiling point of any solution under ordinary atmospheric conditions, is that temperature at which its vapour pressure is equal to the pressure of the atmosphere. The effect of the solution in water of any substance such as a salt, is to reduce the vapour pressure of the liquid and hence to raise the temperature to which it must be heated before it will boil. It thus comes about that saline solutions have b. pts. higher than that of water. Now when steam at the boiling point of water is passed into a saline solution, the vapour pressure of the steam being equal to that of the atmosphere, but greater than that of the solution, the steam condenses in the solution and continues to do so as long as the latter has a lower vapour pressure, or in other words, so long as the solution is not at boiling point. When this point is reached the steam merely blows through the liquid, a sufficient quantity condensing to replace the heat lost by

radiation, &c. It is to the liberation of the latent heat of the steam on condensation, that is due the heating effect which we have been considering. When we reflect how great is the amount of this latent heat (some 537 calories for each cubic centimeter of water condensed from steam) we can readily understand why such striking thermal effects are produced.

The fact of condensation taking place causes dilution of the solution with consequent reduction of b. pt., unless a supply of the solid salt is maintained so as to keep the solution constantly saturated.

Taking into consideration all the facts, in my opinion the temperature to which a solution is heated by steam is a truer measure of its b. pt. than that obtained by the application of direct heat. It is well known that the temperature of boiling water varies within quite considerable limits according to the nature of the vessel in which it is contained, and the b. pt. of liquids other than solutions of solids, is always determined from the temperature of the vapour. It is equally well known that saline solutions are very readily superheated when boiled over a flame, and it is highly probable that the b. pt. determined in this way will tend to be too high.

When alcohol of sp. gr. 0.816 is placed in the tube and steam injected, condensation takes place until the liquid becomes heated to boiling, and when this point is reached the liquid has a temperature of 79.1°, that of the escaping vapour being 78.1°. This difference is due to the fact that the vapour is richer in alcohol than the liquid, and accordingly, having a higher vapour pressure, comes away at a lower temperature. The fact that the water vapour escaping from a boiling saline solution has the same temperature as that from boiling water, is due to the same cause.

While experimenting on heating saline solutions with steam, it is interesting to observe the effect on the thermometer placed in the vapour space of the boiling tube, when, through splashing, its bulb becomes covered with the saline solution. When a saturated solution of a moderately soluble salt is under observation and a portion of the liquid carrying particles of the solid salt splashes on to the thermometer bulb, the temperature at once rises to and remains at the same point as the boiling liquid itself. The film of saturated solution on the bulb, being enveloped in steam at 99°, behaves precisely like the mass of solution and maintains the thermometer at the b. pt. of the solution. Sodium chloride shows this extremely well.

The condensation of water from the atmosphere on particles of substances like sugar or salt, when the air is laden with moisture, is due to the same cause, the difference in vapour pressure of the film of solution adhering to the salt, and that of the moisture in the atmosphere, transference of water vapour always taking place in the direction of least vapour pressure. This was originally termed "invaporation" by Graham, who experimented with saline solutions in air saturated with water vapour, and determined the rate of condensation in the solutions. (*Edinburgh Jour. of Science*, 16, 1828, 249. Report British Association, 1886, 207.)

In the course of some of my earlier experiments I used a vessel of boiling water in which to place the tube containing the solution under observation, but I quickly found that, far from being as efficient as the cotton wool lagging subsequently used, the boiling water actually cooled the tube.

A knowledge of this property of steam whereby solutions are heated to temperatures considerably above that of the steam itself, may be of practical importance in chemical industries where saline solutions require heating to temperatures greater than 100°. Again, in some cases, as for instance, in the course of operations in the manipulation of sugar and other organic substances, considerable over-heating may readily occur through the mistaken idea that the temperature of the steam used determines the limit of heating possible.

DISCUSSION.

Mr. W. A. Dixon said he had found that a steam spray immediately destroyed the prickly pear; was this partly due to the temperature being raised?

Dr. R. GREG SMITH thought this matter had been explained in a clear and forcible way, and inquired the temperature effect of direct steam on agar was. This substance was used for bacteriological purposes, and could only be obtained as a solution after long and tedious digestion. Would direct steam hasten the process?

Mr. F. STEEL, in reply, said the efficiency of steam in killing prickly pear would be due to liberation of latent heat and thorough distribution; but unless the steam diffused into the sap, the temperature would not rise above that of the steam itself. As regards the effect of direct steam on agar-agar, he had no doubt this substance would behave in the same manner as a salt.

Obituary.

THE RT. HON. SIR BERNHARD SAMUELSON, BART., F.R.S.

CHEVALIER OF THE LEGION OF HONOUR. CHAIRMAN OF THE ROYAL COMMISSION ON TECHNICAL EDUCATION. FORMERLY PRESIDENT OF THE IRON AND STEEL INSTITUTE (1883-4). ORIGINAL MEMBER OF THE SOCIETY OF CHEMICAL INDUSTRY.

Sir Bernhard Samuelson was born November 22, 1820, and was the son of Mr. Samuel Henry Samuelson, merchant, of Liverpool and Hull. He was educated privately, and entered on his mercantile career at his fifteenth year as apprentice in a general mercantile office in Liverpool. Shortly after the expiration of his indentures, he was placed in charge of the continental transactions of Messrs. Sharp, Stewart and Co., engineers, of Manchester, and from 1846 to 1848 he was engaged in establishing the railway works at Tinsley. He returned to England in 1848, and bought an iron-ment works and foundry in Banbury. The concern was at that time very small, but in his hands it grew into a very large business. Five years after, he erected his blast furnaces at Middlesbrough, to which he subsequently added collieries and iron mines. In 1853, Mr. Samuelson made the acquaintance of the late Mr. Vaughan, and these two jointly transformed Cleveland into the greatest iron-producing centre in the world. Not content with making pig-iron, Mr. Samuelson determined also to manufacture finished iron, and in 1870, he erected the British Iron works at Middlesbrough, which cover 20 acres. His preliminary experiments in steel-making cost him £25,000. Sir Bernhard Samuelson was the first ironmaster in this country practically to recast the merits of the closed coke-oven, with recovery of coal tar and ammonia, and its superiority over the beehive ovens, which yield smoke and fumes contaminating the surrounding country, instead of recording products of value. To Sir Bernhard Samuelson probably the nation is indebted more than to any other man for its knowledge of the relative position which England occupies among the competing industrial peoples of the European Continent and of the Transatlantic States. For three or four years he occupied the position of chairman of the Association of Chambers of Commerce of the United Kingdom. In 1867, at the request of the Vice-President of the Committee of Council on the Government, he visited the principal manufacturing centres of Great Britain and the Continent, and reported on the education of the industrial population. The report was published in a Parliamentary paper, and was for years referred to in all debates on technical education. This work, he followed up by a Parliamentary inquiry, in 1868, into the education of the workmen of our manufactories, and was chairman of a committee, whose reports were adopted by the House of Commons. Sir Bernhard Samuelson was also appointed chairman of the Royal Commission on Technical Instruction, the labours of which extended over the years 1882, 1883 and 1884, and em-

examination into the systems in use in all parts of the United Kingdom and a great portion of the European Continent. In this he was associated with the first president of this Society, Sir Henry Roscoe, together with Messrs. Woodall, Redgrave, Swire Smith, Slagg, and Ph. Magnus. (This Journal, 1882, 139.) The justly report of this work has become the standard authority upon the questions it deals with. It was this report which earned Samuelson his baronetcy in 1884, and he was soon after elected a member of Privy Council. He was also a Fellow of the Royal Society, a Chevalier of the Legion of Honour, and, in

1871, became the recipient of the Telford Gold Medal for a paper on improvements in iron manufacture. Of the Iron and Steel Institute, he occupied the presidential chair for the two years 1883-1885. In 1878, Sir Bernhard Samuelson was elected president of the Cleveland Ironmasters' Association, and he was the first president of the Agricultural Engineers' Association. As an employer, he was liberal and considerate to his workpeople, whilst he gave generous support to technical schools and other institutes in Middlesbrough and Banbury. He died Wednesday, May the 10th, in his 85th year, after a brief illness.

PLANT, APPARATUS & MACHINERY.

UNITED STATES PATENTS.
Granular Materials; Apparatus for Cooling — F. Holl, Worms, Germany. U.S. Pat. 1,389,007, May 16, 1905.
Ice — Pat. 342,619 of 1904; this J., 1904, 929.—T. F. B.
Freezing Liquids; Process of — J. H. Wallace, San Francisco, and J. B. Speed, Berkeley, Cal. U.S. Pat. 1,389,004, May 2, 1905.
The process consists in first evaporating the liquid under conditions of highest temperature and pressure, and then condensing the vapour formed under the same pressure. The liquid is then given up during this condensation is applied to a second portion of the liquid, which is

contained in a vessel which surrounds that in which the first condensation takes place. The second evaporation takes place at a lower temperature and pressure, and the vapour is condensed at the same lower pressure, and in a vessel surrounding that in which the second evaporation is effected, and gives up its heat, in turn, to a further portion of liquid contained in another vessel surrounding this condenser, in a similar manner as before. This process may be continued at diminishing temperatures and pressures and in similar annular vessels as far as desired.—W. H. C.

GERMAN PATENTS.

Centrifugal Apparatus with Air-Heating Device.
R. Fänder. Ger. Pat. 157,264, May 13, 1902.
Below the drum of the centrifugal apparatus is disposed

a heating pipe with a number of branch tubes. The air is heated by means of naked flames issuing from the tubes, and it escapes through openings in the upper wall of the heating pipe. The apparatus is intended chiefly for laboratory purposes, the heating of the air being effected by means of a spirit lamp or the like. A. S.

Filter Element for Filter Presses, with Annular Projections on both sides pressing against the Filtering Material.
G. Fromme. Ger. Pat. 157,588, June 25, 1903.

The circular frame of the filter element is provided, just above its lower edge, with an annular projection of triangular cross-section, and the filtering material is held in place by means of a corresponding projection on a lattice-work plate, which is placed on the upper edge of the frame. When several such elements are combined to form a filter-press, the lattice-work plate abuts against the lower edge of the frame of the adjacent filter element, and forms, with the annular projection on the latter, an inlet channel for the liquid to be filtered. —A. S.

II.—FUEL, GAS, AND LIGHT.

Wood-gas for Power Purposes and Gas Generators.
G. M. Douglas. Inst. of Mining and Metall., April 13, 1905. [Advance Proof.]

The author describes the use of wood gas for power purposes at the concentrating works and mine of the Most zuma Copper Co., Sonora, Mexico. The central power station contains ten gas-engines of the Crossley "Otto" type, of which eight are single-cylinder engines, 18½ in. diameter by 24 in. stroke, giving a maximum of 80 h.p., whilst the other two are double-cylinder engines, 18½ in. diameter by 27 in. stroke, from which 175 h.p. can be obtained. The engines are connected by belts to dynamos of 65 kw. for the single cylinder and 150 kw. for the double-cylinder engines. The dynamos are shunt-wound machines operated in parallel, and generate direct current at 260 volts. The current is supplied from the power station by a motor-driven generator giving at 6600 volts 3-phase alternating current of 25 cycles, and at the mine, which is 6 miles distant, is "stepped down" by transformers to 230 volts. The wood-gas is produced in a slightly modified Loomis-Pettibone gas generating plant, consisting of two duplicate sets, in each of which are two generators and a boiler, whilst a wet scrubber and an exhauster of Root's positive pressure type are common to both sets. In starting the gas generators, coke is placed on the grates to a depth of 2–3½ ft. or more, if the wood to be used contains a large proportion of volatile matter. Small and light wood is fed on to the coke to a depth of about 3 ft., and the blower is set working and the fires started. When the coke is incandescent, fast feeding with heavy wood is necessary, until a bed of unincandescent charcoal and partly consumed wood is formed to a depth of about 2 ft. above the coke, when the gas may be supplied to the engines. At intervals steam is supplied to the generators, and a small quantity of water-gas made in order to loosen the bed of fuel, but it is stated that the practice of making water-gas and producer gas alternately for long periods causes an uneconomical use of fuel and an unsteady supply of gas. The wood gas produced, has a calorific value of 135·6 B.T.U. at 62° F. and under normal pressure, and has the following average composition:—Hydrogen, 19·5; carbon monoxide, 13·45; methane, 2·48; olefines, 0·31; carbon dioxide, 15·45; oxygen, 0·25; and nitrogen, 48·5 per cent. This gas is stated to give better results in the engines than gas from coal having the same calorific value, but in which the proportions of hydrogen and carbon monoxide are reversed. In a run of four days and 23 hours, the output and fuel consumption were as follows:—

Coke placed in generators	8,590 lb.
Wood used in firing up	7,400 lb.
Duration of run	119 hours.

Total amount of ash from generators	14,124 lb.
Amount of coke recovered	2,572 lb.
Total amount of wood used	138,840 lb.
Total amount of coke used	5,918 lb.
Total amount of combustible	144,768 lb.
Percentage of water in wood	19·8
Percentage of ash in wood	10·3
Calorific value of gas (average of 35 tests)	116·4 B.T.U. (a) 39,700 kw. h.p.
Total output of power house ...	53,217 h.p. (a)
Average power	447·2 elect. h.p.
Consumption per electric h.p. = 2·6 lb. of wood and 0·11 lb. of coke.	

In summing up, the author states that the great advantage of a gas-engine plant lies in its extreme economy of fuel; in nearly every other respect a gas-engine is at a disadvantage compared with a steam-engine.—A.

Gas; Cleaning of Blast-Furnace —. A. S. Iron and Steel Inst., May, 1905. [Advance Proof.]

The dust carried over by the "waste-gas" has been a great obstacle to its successful use in large gas engines. For this purpose the gas must be quite free from dust, and the removal of the last 0·1 grm. per cu. m., though expensive, will pay for itself in longer life and decreased cost of repairs. The cleaning should be effected in three stages:—

1. The ordinary dry-cleaning by means of dust chambers and dust-catchers.
2. Wet-cleaning by means of (a) stationary cleaners or "scrubbers," such as the Zscheck cleaner; (b) revolving machines or "atomizers," such as the Stein apparatus; or (c) slowly revolving "fresh-contact cleaners." The Bian apparatus, the earliest of fresh-contact cleaner, has proved very effective. It consists of a horizontal cylindrical casing through which the gas is passed from end to end. In its axis is a revolving shaft to which a number of circular perforated discs of a diameter but little less than the inside diameter of the casing are bolted, whilst between these are a series of deflecting plates, attached to the casing. The gas being drawn through the machine is thus compelled to approach the centre after each passage of the perforated discs. The outer shell is filled with water up to the bottom of the centre shaft, the discs and their perforations are, therefore, washed at every revolution of the apparatus, and ascend from the bath covered with thin film of water. The dust which settles to the bottom of the bath is drawn off from time to time by means of sludge valves. The Schulin cleaner is an improvement on this apparatus, designed with a view of securing larger capacity, a better wetting of the perforated surfaces, and a more uniform and constant removal of the dust. The gas is drawn through the apparatus by a ventilator, and a safety valve to prevent the drawing in of air in case of interruption to the flow of gas and possible formation of explosive mixtures is provided. This consists of a small gasometer having a diameter of 8 ft. with a lift of 6 in., and so balanced that it will drop when the pressure falls to a quarter of an inch column. Finally the gas is forced through a coke drier, whence it passes through a mushroom-shaped valve into the general gas-main. Gas for the power is drawn from this main by electrically-driven fans, supplied with water, and discharged into a second smaller drier, whence it is sent to the engines. The total power required is as follows:—

- To pass 40,000 cu. ft. of gas per minute against head of 2 in. water, 36½ h.p.
 - To pump cooling water, 8 h.p.
 - To finally clean 10,000 cu. ft. of gas per minute, 8000 galls. of spraying water per hour, 65 h.p.
- quantity will supply gas engines of from 5000 to 6000 h.p. —J. C.

Arcs: Metallic [Titanium] —. I. Ladoff. Zhot. World and Eng., 1905, 45, 757; Electrician, 1905, 55, 120–122.

The results of experiments with electric arcs with titanium and mixtures of iron and titanium oxides are given. These were employed either for both positive and negative electrodes.

negative electrodes, or in conjunction with a carbon or other positive, with good results. The light produced from ferro-titanium and rutile (oxide of titanium and titanic acid) is pure white in appearance, and an efficiency of 3 watts per candle can be attained. In general, the results obtained are between that of an ordinary incandescent lamp and the so-called "flame" arcs.—R. S. H.

ENGLISH PATENTS.

Gas Fuel; Manufacture of — from Coal Mine Gas or Dust Coal. T. Rouse and H. Cohn, London. Eng. Pat. 9071, April 20, 1904.

A powdered material is mixed with a hot solution of an emulsion of petroleum (obtained by levigating petroleum in lime with petroleum) and four parts of water in 80 parts of water.—J. H. C.

Burners, Gas; for Heating Purposes. A. W. Onslow, Woolwich. Eng. Pat. 24,064, Nov. 7, 1904.

To obtain a powerful, high-velocity flame for use in heating furnaces, rivet forges, annealing machines, &c., and to utilise high-pressure illuminating gas for these purposes, gas-burners are constructed in the following manner:—A gas-supply pipe *d* extends through the end cap *c* of the burner tube *a*, the cap being provided with air inlets *c'*. The supply pipe has a screw-threaded portion *e*, where it passes through the cap, so that its outlet *f* can be adjusted in a proper relative position to the burner nozzle *b*. The supply pipe can be fixed in that position by means of a lock-nut *g*. Different forms of burner nozzles may be employed. By fixing a pin across the burner outlet, and not through its centre, the current of gas is split up on emanating from the nozzle; by this device the pressure of the gas employed can be varied within large limits. The burner may be rendered portable by fitting a wooden handle on it.—R. L.

Producers; Impts. in —. W. Towns, Liverpool. Eng. Pat. 29,170, Dec. 30, 1904.

A producer, which may be cylindrical or of any other convenient shape, consists of an outer casing lined with refractory material, and supported on girders over the sealed ash-pit. The blast of air, or of air and steam, is conveyed to a chamber in the ash-pit, which has a sliding door, and is then distributed both upwards and sideways through the fuel by means of a tapered cone or pyramid, which also acts as a grate to support the fuel. The gas is taken off all the top of the producer through an annular opening communicating with an annular flue which carries the top of the producer. Doors are provided for the purpose of moving the dust which accumulates in the annular flue. The charging chamber, fed from a hopper, is placed at the top of the producer, so that the freshly-charged fuel is being partially distilled, is not overheated and does not become adherent to the sides of the chamber.—W. H. C.

Illuminating; Purification of —. J. Bernheim and M. Wagner, Paris. Eng. Pat. 9206, April 21, 1904. Under Int. Conv., April 22, 1903.

Gas coming from the meter is passed for the final purification through a coil in which moisture and hydrocarbons, such as naphthalene and anthracene are condensed, and may be run out through a water-sealed pipe.

The gas then enters the purifier lined with material containing three perforated shelves, which are charged partly with a mixture of wood charcoal and wood fibre and partly with a mixture of ferrous chloride, copper sulphate, iron sulphate, ferric oxide and sawdust. The gas coming from the purifier passes through a drier, containing on two shelves layers of hay and animal black and an open box filled with quick-lime. The appliance is intended for private installations.—R. L.

Gas; Purification of —. T. Redman, Bradford, Eng. Pat. 9514, April 26, 1904.

Impurities suspended in crude gas can be extracted by causing the gas to pass through fine gauze screens. An endless belt of fine gauze arranged on two rollers is employed, so as to form two screens in the path of the flow of gas and rotating in a suitable casing, the gas passing the screens in two different directions, although maintaining its current towards the gas holder. To keep the perforations clear and to avoid clogging of the fine-meshed gauze, the lower part of the casing may be charged with a suitable liquid, which, by wetting the gauze, assists in removing the impurities both from the gas and subsequently from the screen. The collected impurities descend into a well at the bottom of the casing. Instead of using a rotating screen a stationary one can be employed; in this case the flow of gas is controlled by a reversing valve.—R. L.

Gas Washers or Scrubbers; Impts. in —. T. Redman, Bradford, Eng. Pat. 12,659, June 4, 1904.

The drums of washers or scrubbers of the rotary type are provided with division plates, between which are placed corrugated plates. On rotating the drums the gas is drawn through openings in the drum casing into the spaces between the corrugated plates and brought into intimate contact with their wetted surfaces, being finally expelled and delivered to the next drum or to the outlet at the end.—W. H. C.

Electrodes; Arc Lamp —. W. S. Weedon, Schenectady, U.S.A. Eng. Pat. 9190, April 21, 1904. Under Int. Conv., April 21, 1903.

To increase the mechanical strength of titanium carbide electrodes, and to prevent crumbling away of the top part when heated, a core of titanium carbide is encased in a copper sheath, preferably deposited electrolytically. The copper or copper oxide, into which the part adjacent to the arc end of the electrode is converted, vaporises only near the arc end, and until vaporised protects the core so that the only consumption of the titanium carbide which takes place is at the surface from which the arcing takes place.—R. L.

Electrodes for Arc Lighting. The British Thomson-Houston Co., Ltd., London. From the General Electric Co., Schenectady, N.Y. Eng. Pat. 14,196, June 23, 1904.

ELECTRODES for arc lamps, consisting of a mixture of oxides of iron and titanium are considerably improved by the addition of chromium oxide. The electrodes are made by charging a thin iron tube with a well-ground mixture of, say, 70 parts of magnetic iron oxide, 30 parts of rutile, and 12½ parts of natural chromite, the whole being initially fused together by an electric arc. The natural chromite gives very good results unless it contains too much aluminium oxide; a mixture of commercial chromium oxide and magnesia may be employed instead of the natural product.—R. L.

UNITED STATES PATENTS.

Coke, Compressed; Process of Producing —. A. D. Shrewsbury. Assignor to the Gas and Fuel Manufacturing Co. of America, Washington, D.C. U. S. Pat. 788,558, May 2, 1905.

THE process claimed consists in discharging the partially

coked material from the coke-oven whilst still in a plastic condition. It is then strongly compressed, returned to the oven and reheated. The process may be repeated as often as is necessary until a block or briquette of the desired density is obtained.—W. H. C.

Fuel Briquette and Method of Making same.—A. Gaud and A. Levy, Paris. U.S. Pat. 790,106, May 16, 1905.

SEE Fr. Pat. 349,214 of 1904; this J., 1904, 745.—T. F. B.

Gas; Apparatus for Manufacturing.—B. E. Elford and C. Ellis, New York. Assignors to Eldred Process Co., New York. U.S. Pat. 789,266, May 9, 1905.

A RETORT bench is combined with a gas producer adapted to gasify bituminous coal. The retorts are provided with a suitable heating device, such as a coke gas generator; the products of combustion of the latter mixed with air in certain proportions, or any other mixture of oxygen and carbon dioxide in predetermined proportions is introduced into the gas producer. Means are provided for mingling the retort and producer-gases.—R. L.

Producer Gas; Process of Obtaining.—A. Desgraz, Hanover, Germany. U.S. Pat. 790,113, May 16, 1905.

SEE Eng. Pat. 21,333 of 1904; this J., 1905, 80.—T. F. B.

Calcium Carbide Ingots; Utilising Scale from.—I. K. Edmunds and J. Seades, Sault Ste. Marie, Mich., Assignors to Union Carbide Co., Niagara Falls, N.Y. U.S. Pat. 781,255, March 7, 1905.

THE scale with which ingots of calcium carbide are covered on production, is removed from the ingots, and is subjected, in a subdivided state, to the action of sufficient water to decompose the contained carbide, the acetylene evolved being collected. The residue is then dried and, preferably after addition of carbon, is directly smelted in the carbide furnace; or it may be added to the normal furnace charge of lime and carbon.—E. S.

Electrode; Arc.—D. A. Holmes, S. A. Tucker and E. Van Wageningen, New York. U.S. Pat. 789,609, May 9, 1905.

THE arc electrode consists of zirconium carbide, mixed with a suitable binding material.—R. L.

FRENCH PATENTS.

Peat-Charcoal; [Artificial Fuel] Process for the Manufacture of.—from Peat. Central Torfkohlen-Ges. m.b.H. Fr. Pat. 349,139, Dec. 8, 1904.

TO obtain a solid peat-charcoal from peat, the air-dry material is charged into retorts and heated by producer gas without access of the air, until all moisture and the light hydrocarbons are eliminated, while the heavy hydrocarbons which may be transformed into tar are retained with the carbon of the peat. The necessary temperature varies, and has to be regulated according to the physical and chemical properties of the material, but rarely reaches 400°C. The product obtained in the retorts is a uniform mixture of carbon powder and heavy hydrocarbons and is liable to auto-combustion. Whilst yet hot and still excluding the access of air, it is carried into hydraulic presses with moulds heated to such a temperature that no radiation of the heat of the material can take place. The product leaving the presses, being physically and chemically different from the original peat, does not absorb any moisture even after cooling, is not friable and is greatly enriched in carbon.—R. L.

Gas and Air; Process and Apparatus for Preparing Mixtures of.—Selas Ges.m.b.H. Addition, dated July 11, 1904, to Fr. Pat. 338,967, Aug. 19, 1903.

IN connection with the apparatus described in the main patent (Eng. Pat. 17,788, 1903; this J., 1904, 859), special check valves are provided on the suction pipes, so that during each suction period, the valves on the return suction pipes are opened as well as the suction valves, whilst all the pipes are closed during the delivery stroke.

Furthermore, means are provided for opening and closing the suction and return pipes during the working of the compressor.—C. S.

Gases Free from Tarry Matter and of High Caloric Value; Process and Generator for Producing Combustible.—Fr. Pat. 349,107, Nov. 10, 1904.

SEE Eng. Pat. 21,333 of 1904; this J., 1905, 80.—T. F. B.

Gases; Process for Treating [Drying].—J. Gaudy. Fr. Pat. 349,109, Nov. 19, 1904.

SEE Eng. Pat. 25,213 of 1904; this J., 1905, 539.—T. F. B.

Mantle; Self-lighting.—E. A. L. Rouxville and P. S. Michaux. Fr. Pat. 349,023, Nov. 9, 1901.

THE interior surface of an incandescent mantle is wholly or partially impregnated with a mixture of platinum or a platinum compound and a refractory material, such as alumina, lime, magnesia or silicates, preferably with aid of a volatile liquid. After the first ignition the action of the gas on the platinum will render it incandescent whereby the gas is lighted. The substance may be deposited on the central or lateral rod which some supports the mantle. A suitable mixture providing material for 200 mantles, consists of 3 grms. of platinum chloride, 0.01 grm. of magnesia, and 60 grms. of alcohol or essence of turpentine.—R. L.

Filament, Indestructible, for Lighting and Heating.—G. Michard and E. Delasson. First Addition, dated Dec. 7, 1904, to Fr. Pat. 346,307, Sept. 17, 1904 (this J., 1905, 125).

THE filament may be coloured by adding metallic oxides to the ingredients used, in order to obtain a coloured mantle. Thus, chromium oxide (e.g., 2½ per cent.) destroys the greenish hue of the mantle flame and imparts a colour analogous to that of the electric light.—C. S.

GERMAN PATENTS.

Gas, Illuminating; Process for Increasing the Yield of.—by the Introduction of Water-Gas into the Retort. W. Bentrup. Ger. Pat. 157,470, March 29, 1903.

THE claim is for the introduction into the gas retort at the commencement of the gasification process, of water-gas, which has been produced in the known manner by passing steam through the residual coke in an air retort.—A. S.

Gases, Illuminating and Heating; Process for the Recovery of Carbon Bisulphide from.—[by means of Oil or Distillation of Vinasse]. Rositzer Zucker-Raffinerie. Ger. Pat. 157,563, May 19, 1903.

THE gases are washed with oil obtained by the distillation of vinasse. It is stated that this oil not only removes the carbon bisulphide, but is also a solvent of naphthalene.—A.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Pitch, Asphalts and Similar Substances; Determination of the Melting Point of.—M. Wendriner. Z. angew. Chem. 1905, 18, 622—625.

THE method of Kraemer and Sarnow (this J., 1903, 91) gives varying results owing to the difficulty of making the plugs of pitch of uniform shape and exactly the same depth, but especially also owing to differences in the rate at which the temperature rises during the determination. The author has accordingly modified the method in the following manner:—The heating-bath is brought to a temperature about 10°C. above the melting-point of the pitch, as determined in a preliminary test, and is maintained at this temperature during the determination. In the heating-bath is placed a wide test-tube enclosing a narrower tube closed at the end by the plug of

The pitch is covered with mercury, into which a thermometer dips, and the m. pt. is taken as the temperature indicated by this thermometer at the moment (invariably after about 8-10 mins.), when the mercury drops through the plug of pitch. Three or four plugs of pitch are prepared for each determination in the following way:—A glass tube 16 cm. long and 8 mm. wide, 1 mm. thick, and with one end ground perfectly flat, is fixed in a clamp, and a glass rod 20 cm. long and 7½ mm. thick is inserted from below until the end is exactly 10 mm. from the upper end of the tube. Into the hollow space left in the upper portion of the tube, a drop of water is introduced, and the glass rod is turned a little, so that the capillary space around it becomes filled with water. The water is then removed by filter paper and by gently warming the tube. The molten pitch, in a thinly fluid condition, is dropped into the hollow space, allowed to cool, the excess cut off level with

edge of the tube, and the glass rod withdrawn. The interior of the tube is now dried by means of a glass covered with filter paper, and 10 grms. of mercury introduced. The thermometer is fixed in the tube by means of a rubber ring, so that its bulb is, as far as possible, immersed in the mercury, but does not touch the pitch. The tube is then suspended within the wide tube (20 cm. long by 25 mm. wide) which serves as an air-bath, by means of a cork 20 mm. high, and a guide-rod (see Fig.). The wide tube is provided with a cork by which it can be suspended from the cover of the air-bath. In the preliminary test, the water in the air-bath is brought to the boil, the air-bath containing the test tube, closed by the plug of pitch, is introduced, and the temperature at which the mercury drops through the pitch is noted. The air-bath is then removed, allowed to cool to the ordinary temperature, and fitted with a test tube with a pitch stopper. The heating-bath is used to cool to a temperature of 10° C. above the m. pt. of the pitch, and is maintained at this point during the true determination, which is carried out in the same way as the preliminary test. Two or three control tests should be made, and the results should not differ by more than a few tenths of a degree.—A. S.

Antum; Detection of Adulterants in Natural — B. Malenkovic. XXIII., page 638.

UNITED STATES PAT.

Wood-Distilling Apparatus. Z. E. Fox, St. Helena, Cal. U.S. Pat. 789,271, May 9, 1905.

The apparatus consists of a cylindrical body tapering towards its upper end and containing a furnace in its lower portion; a smoke-box, with chimney, is attached to it in its upper portion; and a retort chamber arranged between the furnace and smoke-box. The partition between the furnace and retort chamber is of conical shape; it is formed of spaced sheets and is inclined towards an outlet valve. Cylindrical flues pass from the furnace through the retort chamber to the smoke-box.—R. L.

Distilling Apparatus [for Wood]. W. B. Harper, Lake Charles, La. U.S. Pat. 789,691, May 9, 1905.

A HORIZONTAL rotatable retort shell with fixed heads is heated by a furnace. A steam-supply pipe enters the retort through one of the heads, and valved vapour-outlet pipes pass out through the heads. Through the centre of the front head of the retort passes a feeding-conveyor, extending into the retort, and through the rear head, a discharge-conveyor. A chain, fixed at the front end of the retort, extends loosely along the bottom, and serves to carry the material forward to the discharge end, where it is raised by lifting-plates and delivered to the discharge-conveyor. In connection with the discharge-conveyor is a pressing-device, by which any liquid is separated from the residue, this liquid passing out through a pipe at the bottom of the rear head of the retort.—A. S.

IV.—COLOURING MATTERS AND DYE-STUFFS.

Organic Compounds; Solubility of some — in Water at Different Temperatures. J. Dolinski. Chem. Polski, 1905, 5, 237—240. Chem. Centr., 1905, 1, 1233.

THE author determined the solubility in water, at temperatures ranging from 0° to 100° C., of four organic acids largely used in the manufacture of dye-stuffs. The solubility of *α*-naphthylamine-*o*-monosulphonic acid (grms. of substance in 100 grms. of solution) was as follows:—0° C., 0.24; 10°, 0.32; 20°, 0.41; 30°, 0.52; 40°, 0.65; 50°, 0.80; 60°, 1.00; 70°, 1.26; 80°, 1.78; 90°, 2.25; and 100° C., 3.10 grms. The results obtained with the three other acids are expressed in the following formulae wherein *x* is the percentage solubility (grms. of substance per 100 grms. of solution) and *t* is the temperature:—
For picric acid: $x = 0.67 + 0.013t + 0.000195t^2 + 0.0000028t^3$
For sulphamic acid: $x = 0.64 + 0.0152t + 0.00041t^2$
For naphthionic acid: $x = 0.027 + 0.00024t - 0.00000255t^2 + 0.000000205t^3$.—A. S.

Anthragallolamide. F. Böck. Monatsh. Chem., 1905, 26, 571—593.

THIS compound is obtained by the addition of a concentrated solution of ammonium chloride to anthragallol dissolved in excess of dilute potassium or sodium hydroxide solution. It is also produced by exposing finely powdered anthragallol to the action of ammonia and subsequently heating the ammonium salt at 130° C. until it ceases to lose water, and all excess of ammonia has been removed. The amide so obtained is of great purity; it forms with alkali a fine blue solution, is very sparingly soluble in most organic solvents, but dissolves readily in hot pyridine, nitrobenzene, and aniline. It yields an anhydrous diazo compound when subjected to the action of amyl nitrite in strongly acid alcoholic solution, which is converted into xanthopurpurin when reduced in alkaline solution by stannous chloride.—D. B.

Flavinduline; Conversion of —, with Methylene Compounds. F. Sachs and G. Pargellini. Ber., 1905, 38, 1742—1747.

ONE of the authors has previously shown that flavinduline, as a type of the azonium bases, readily reacts with methylene compounds, yielding characteristic colorations

(this J., 1899, 129). The condensation product with deoxybenzoin had been prepared, and from the fact that its alcoholic solution when treated with a few drops of hydrochloric acid, yielded an intensely blue-colored salt, it was concluded that the two different colours were due to the presence of two different chromophore groups of the ortho- and paraquinone types. In continuing this investigation, the authors were able to confirm the existence of two isomeric salts in the two colored solutions, but attempts made with a view of obtaining a similar pair of salts from other known types of the same series gave negative results. The condensation products of flavinduline with the following compounds were prepared: Ethyl acetoacetate, benzyl cyanide, acetylacetone, ethyl malonate, ethyl cyanoacetate, and malononitrile. In each case the same coloration effects were produced, but the new compounds gave by analysis a molecule less water than the substance $C_{14}H_{12}N_2O_2$ which had been obtained previously by the condensation of flavinduline with deoxybenzoin.—B. B.

Nitrobenzyl Azine Dye-stuffs from Benzeneazo Compounds; *New Synthesis of* —, T. Vilman and J. S. Ankersmit. *B. G.*, 1905, 32, 1811—1822.

When α -aminoazo bodies are heated with 3-naphthol or its hydroxy derivatives, naphthalazines are formed with elimination of aniline and water. Thus if Chrysoline is used, we have

The 2,7- and 2,3-dihydroxy derivatives of naphthalene react even more vigorously than β -naphthol. The Chrysoline may be replaced by benzen-azo-toluylen-diamine, α -aminoazobenzene or benzen-azo- β -naphthylamine. The temperatures of reaction employed varied between 150 and 250° C. The products are yellow bodies, the solutions of which show green or blue fluorescence. By the action of 2,3-dihydroxynaphthalene on benzen-azo-toluylen-diamine, aminoanilidomaphthotetrazine was also formed as a by-product, by the interaction of aniline with a hydroxy-group of the primary product.—E. F.

Dye-stuffs: Differentiation of Blue Sulphur —, A. Lüttringhaus. *XXIII.*, page 638.

ENGLISH PATENTS.

Indoxyl, its Homologues and their Derivatives. Improved Manufacture of —, O. Jarry, London. From the Basle Chemical Works, Basle, Switzerland. Eng. Pat. 15,223, July 7, 1904.

INDOXYL is formed by heating together an alkali salt of phenylglycin, metallic sodium and an alkali in presence of alcohol. The alcohol prevents decomposition and increases the yield. The phenylglycin may be replaced by its homologues or derivatives, substituted indoxyls being thus obtained. For example, 15 parts of sodium and 40 parts of the potassium salt of phenylglycin are added, with stirring, to 140 parts of anhydrous alkali hydroxide at about 250° C. Thereupon 10 parts of absolute alcohol are added as vapour, in a short time, and with increasing rapidity by the aid of a current of hydrogen, and the heating continued until the amount of indoxyl no longer progresses. The hydrogen takes no part in the reaction, and the alcohol may be added as vapour or liquid in absence of hydrogen (see also U.S. Pat. 761,410 of 1904; this J., 1904, 712).—E. F.

Dye-stuffs [Azo]: Manufacture of Yellow Mordant —, O. Jarry, London. From Farbwerke vorm. Meister, Lucius and Brüning, Höchst on the Maine, Germany. Eng. Pat. 14,972, July 4, 1904.

SEE Ger. Pat. 158,148 of 1904; this J., 1905, 512.—T. F. B.

UNITED STATES PATENT.

Dye-stuff, Azo. P. Julius and E. Fussenegger, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 789,096, May 2, 1905.

SEE Fr. Pat. 348,588 of 1901; this J., 1905, 494.—T. F. B.

GERMAN PATENTS.

Dye-stuff, Sulphide: Process for Preparing a Red-Violet —, Kalle and Co. Ger. Pat. 157,731, June 12, 1903.

A SULPHIDE dyestuff which dyes red-violet shades fast to washing, soaping, and light, is obtained by methylhydroxyphenylrosinduline (see Ger. Pat. 158,077, abstract) with sodium sulphide and sulphur.—T. F. B.

Trihydroxyphenylrosinduline [Azoine Dye-stuffs]; Process for Preparing —, Kalle and Co. Ger. Pat. 157,771, Dec. 4, 1902, and 158,100, Aug. 29, 1903.

SUBSTANCES such as the dyestuffs obtained by combining diazo compounds with α -naphthylamine, which can be converted into 1,4-naphthylenediamine, are heated with p -aminophenol and hydrochloric trihydroxyphenylrosinduline being produced. The compound may also be obtained by heating 1,4-naphthylenediamine with p -aminophenol and hydrochloric acid, and then oxidising the product, preferably with an α -nitro-compound; also by heating α -naphthylamine and an aromatic nitro compound (or also α -nitronaphthylamine) with p -aminophenol in presence of hydrochloric acid. The second patent relates to the use of p - or m -nitro compounds as the oxidising compound in the above process; compounds may take the place of a portion of the p -aminophenol. The following example of the process is given: 28.5 kilos. of benzeno- α -naphthylamine hydrochloride and 40 kilos. (4 mols.) of p -aminophenol are heated for five hours at 160°–170° C., and the crude product, washed with hot dilute hydrochloric acid.—T. F. B.

Trihydroxyphenylrosinduline [Azoine Dye-stuff]; Process for Preparing —, Kalle and Co. Ger. Pat. 157,771, Oct. 17, 1903. Addition to Ger. Pat. 158,077, 1902.

TRIHYDROXYPHENYLROSINDULINE may be obtained by heating together the substances described in Ger. Pat. 158,077 (see above) in aqueous solution, instead of melting them together as there described.—T. F. B.

Nitriles: Process for Preparing Acid —, H. Buerger. Ger. Pat. 157,710, Jan. 28, 1902.

SUCH salts or compounds of aromatic amines or their derivatives which liberate hydrocyanic acid from cyanides, and give a neutral reaction product, are mixed with an alkali cyanide in molecular proportions, in presence of some solvent which has little or no solvent action on the cyanide, and an aldehyde or ketone is added to the mixture, resulting in the formation of acid nitriles. The preparation of the nitrile $C_6H_5NH \cdot CH_2 \cdot CH(CH_3)CN$ from aniline hydrochloride, potassium cyanide and acetaldehyde in ethereal solution, is described. One of the advantages claimed for this method is that no free hydrocyanic acid is generated during the reaction.—T. F. B.

Nitriles: Process for Preparing Acid —, H. Buerger. Ger. Pat. 157,840, Nov. 14, 1901.

ACID nitriles of the general formula, $R \cdot NH \cdot LCH_2 \cdot CN$, where R represents an aryl radical and R' an α - or β -hydrogen (excepting ω -cyanomethylaniline and its derivatives), are produced by the interaction of equimolar weights of the bisulphite compounds of "Schiff's base," $R \cdot N \cdot CH \cdot NaHSO_3$, and an alkali cyanide in aqueous solution.—T. F. B.

Nitriles: Process for Preparing Acid —, H. Buerger. Ger. Pat. 157,909, Nov. 14, 1901, and 157,910, Jan. 21, 1902.

NITRILES similar to those prepared according to Ger. Pat. 157,840 (see above) are obtained by adding an alkali cyanide to a mixture of an aromatic amine, an aldehyde (or ketone), and a bisulphite or sulphurous acid. This process avoids the isolation of the Schiff's base, which is not always easy, as in the case of β -naphthylamine. The second specification relates to the preparation of nitrile $R \cdot NH \cdot CH(CH_3)CN$; for this purpose acetaldehyde is used instead of formaldehyde or an aromatic aldehyde.—T. F. B.

Naphthazine Derivatives [Azine Dyestuffs]; Process for Preparing —. Act.-Ges. f. Anilinfabr. Ger. Pat. 7,861, Jan. 31, 1904.

NAPHTHAZINE derivatives are obtained by melting α -amino-compounds with β -naphthol. For example, 10 parts lysosidine are added gradually to 15 parts of melted naphthol, and the mixture heated at about 210–215° C., which temperature aniline and water distil off. The α -aminonaphthazine is purified by heating with naphthol. The product is identical with that obtained from β -naphthylamine and quinone-dichlorodiimide, giving cotton orange shades. Similar products are obtained by the use of benzeneazo-*m*-toluylene diamine, amino-azotoluene.—T. F. B.

Dyeing; Process for Preparing a Yellow Sulphide —. Chem. Fabr. Weiler-ter-Meer. Ger. Pat. 157,862, March 24, 1904.

YELLOW dyestuffs which produce fast, pure greenish-yellow shades on cotton are obtained by heating benzidine nitro- α -methylbenzimidazole with sulphur to high temperatures.—T. F. B.

Hydrolamides; Process of Preparing —. A. Einhorn. Ger. Pat. 158,088, Sept. 23, 1902.

HYDROLAMIDES are obtained by allowing formaldehyde to react with aromatic amides in acid solution for a short time. It is stated that secondary reactions occur if the reaction be prolonged.—T. F. B.

Indoxyl Acid, its Homologues, and their Substitution Products; Process for Preparing —. Chem. Fabr. u. Heyden, A.-G. Ger. Pat. 158,089, Oct. 30, 1904.

INDOXYLACIN- α -CARBOXYLIC acid derivatives of the general formula $R.CO.C_6H_4.NR''CH_2COR'$, (where R and R' are hydroxyalkyl, amino, or alkylamino groups, and R'' represents hydrogen or acid radicals) are heated with alkali compounds of ammonia or its substitution products (the sodium derivative of acetanilide) in presence of an indifferent solvent, at a temperature of about 130° C., to yield of indoxyl derivative is stated to be about 90 per cent. of the theoretical yield.—T. F. B.

Anilic Acid and Formaldehyde; Process for Preparing a Condensation Product from —. Badische Anilin und Soda Fabrik. Ger. Pat. 158,090, Oct. 15, 1903.

CONDENSATION product similar to that obtained according to Ger. Pat. 117,924 (by condensation in ether) is used by the interaction of equimolecular weights of anilic acid and formaldehyde in aqueous solution in suspension for a long period. It is probable that hydroformaldehyde-anthranilic acid is produced as an immediate product. The resulting products are of use in the preparation of indigo; thus, with hydrocyanic acid salts, they are converted into ω -cyanomethyl-anilic acid or its salts.—T. F. B.

Dyeing, Indigo; Process for Preparing Compounds —. Badische Anilin und Soda Fabrik. Ger. Pat. 158,625, Oct. 27, 1903.

TREATING indigo dyestuffs with concentrated aqueous solutions of alkalis or alkaline earths, or with alcoholic solutions of alcoholates, at the ordinary temperature, the products are obtained which are slightly soluble in alcohol. They are easily resolved by water into the dye and the hydroxide, and, owing to the dyestuff being then obtained in a finely divided condition, are thus well suited for the preparation of "fermentation dyes"; the compounds may also be used for silk dyeing.—T. F. B.

Phenolic Oxidation Products [and Sulphide Dyestuffs] from *p*-Chlorophenol; Process for Preparing —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 158,091, Dec. 20, 1903.

LIKE other *p*-substituted phenols, *p*-chlorophenol, on oxidation in aqueous solution together with one of an alkylated *p*-diamine or *p*-aminophenol, com-

pounds resembling indophenols, and containing an *o*-quinonoid grouping:—

where X represents a mono- or dialkylamino, or a hydroxy group. These compounds are converted into azo derivatives by reduction with sodium sulphide, and these latter are converted into sulphide dyestuffs by heating with alkali polysulphides. For example, the product from *p*-chlorophenol and dimethyl *p*-phenyl-medianiline gives a blue dyestuff, converted to green in presence of a copper salt.—T. F. B.

Dyestuffs of the Anthracene Series; Method of Preparing —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 158,257, March 10, 1904.

ANTHRACENE dyestuffs, dyeing wool violet to red shades, modified on chroming to green, are obtained by sulphating the compounds produced by condensing 1-hydroxy-2-methoxy-4-halogenated anthraquinones with aromatic amines.—T. F. B.

Hydroxyanthraquinonylglycolic Acids or Esters; Process for Preparing —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 158,277, Jan. 27, 1904.

MONOHALOGEN substituted acetic esters react with salts of hydroxyanthraquinones, forming the esters of the hydroxyanthraquinonylglycolic acids; these are easily saponified to obtain the free acids. The following compounds are described:—1- and 2-hydroxyanthraquinone-monylglycolic ethyl ester, Alizarin-2-monylglycolic ethyl ester, and Anthrachrysone-3,7-diglycolic ethyl ester.—T. F. B.

***o*-Dimethoxyanthraquinone [Anthracene Dyestuffs]; Process for Preparing** —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 158,278, Feb. 11, 1904.

ORTHO-DIMETHOXYANTHRAQUINONES may be obtained by heating with alkali in methyl alcohol solution, such nitromethoxyanthraquinones as have their substituent groups in the *o*-position to one another. Other nitromethoxyanthraquinones are not subject to this reaction, neither are nitrohydroxy- or nitro-aminanthraquinones. The new dimethoxy compounds serve as intermediate products for the preparation of dyestuffs.—T. F. B.

Dyestuffs, Sulphide; Method of Preparing Yellow —. K. Oehler. Ger. Pat. 158,662, Feb. 27, 1904.

THE product obtained by the condensation of 2,4-toluylenediamine and *p*-toluenesulphochloride (2 mols.) is heated with sulphur to a high temperature, preferably in presence of some high boiling aromatic amine; by heating the resulting products with an alkali hydroxide or sulphide, dyestuffs are obtained which dye fast yellow shades, scarcely modified by chroming.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Chromaline D [Mordant]. A. Abt. Bull. Soc. Ind. Mulhouse, 1905, 75, 84–86.

CHROMALINE is prepared, according to Fr. Pat. 291,471, by the reduction of chromic acid with glycerol or other polyhydroxylated aliphatic compounds under such conditions that the latter are not completely oxidised. The author states that better effects are produced by printing on wool with the help of this mordant than when chromium acetate or fluoride is used, and that the difference is specially noticeable in the case of certain mordant dyestuffs, for instance, Anthracene Brown. When equivalent quantities of the three mordants, *i.e.*, quantities containing equal amounts of chromium, were used, Anthracene Brown yielded bright, very fine and intense shades when fixed with chromaline, whereas the shades obtained with

chromium acetate were weaker, redder and less beautiful; with chromium fluoride the shades were greener and duller. The results obtained when equal quantities of chromaline of 25 B. (containing 7.5 per cent. of chromium oxide) and of chromium acetate of 20 B. (containing 11.5 per cent. of chromium oxide) were used, differed but little in shade and intensity from those described above. The author also states that the results obtained by the use of chromaline in printing on wool are faster to tilling and sharper than those obtained with other chromium mordants. He ascribes these results to the fact that chromaline is dissociated much more easily than the other compounds. —E. F.

Chromaline [Mordant]: Report on A. Abt's Notes on —. R. Kaeuffer, Bull. Soc. Ind. Mulhouse, 1905, 75, 86—88. (See preceding abstract.)

THE author is unable to confirm the results of A. Abt. It is true, he says, that the brown produced with Anthracene Brown and chromium acetate is less intense and redder than that produced with the help of chromaline; but, on the other hand, a distinctly brighter and better brown is produced with chromium fluoride than with either of the other mordants. Similar results were obtained with Alizarine S, Anthracene Blue, Mordant Yellow R (Badische), and Alizarine Blue-black (Bayer). The results obtained with the aid of chromium fluoride were sometimes less clear than those obtained with chromaline, but of greater practical value. When equal quantities of chromaline of 25 B. and of chromium acetate of 20 B. were used for fixing, the shades produced with the latter were generally faster to tilling and to potting. When employed in equivalent quantity, chromaline yielded faster shades than the acetate, but they were not as fast as those produced with chromium fluoride. Seaming tests did not show appreciable differences. The author steamed in a wooden chest in his experiments, whereas A. Abt used an autoclave, which may account for differences. —E. F.

Trinitrobenzene Derivatives on Wool and Silk: Tintings of —. E. O. Sommerhoff, Z. Farben-u. Textil-Ind., 1905, 4, 209.

ON boiling woollen yarn with distilled water containing 0.1 gm. of trinitrobenzene per litre, the wool is coloured a faint yellow. If ordinary spring water be used, a reddish-brown coloration is obtained. Silk behaves similarly. The trinitrobenzene separates unchanged on cooling. If picryl chloride be used with distilled water, the wool takes a deep orange-red colour although the dye-bath remains a pale yellow. With silk an orange-yellow colour is obtained. In neither case is free hydrochloric acid liberated so that the colour cannot be due to the formation of picric acid, which would, besides, dye wool a light yellow. These results are favourable to the "chemical theory" of dyeing. —A. R. S.

Aniline: Oxidation on the Fibre of the Higher Homologues of —. S. Kirpitschnikoff, Z. Farben-u. Textil-Ind., 1905, 4, 233—234.

ORTHO-, meta- and para-toluidine, xylydine and cumidine were printed on cotton material and oxidised on the fibre with sodium chlorate and potassium ferrocyanide in the manner usual in the production of Aniline Black. The colours obtained were: *o*-toluidine, dark violet; *m*-toluidine, blackish-violet; *p*-toluidine, chestnut-brown; xylydine, black; cumidine, brown. The dyeings are stated to be little changed by soaping, but are inferior to those with Aniline Black, in fastness to dilute sulphuric acid, chlorine and light. The nearest to Aniline Black in point of durability is Xylydine Black. —H. L.

ENGLISH PATENTS.

Flax, Jute and Similar Fibres: Process of Treating — for the purpose of Bleaching. G. de Kenckelaere, Brussels. Eng. Pat. 13,773, June 17, 1904.

It is stated that "all the organic and other substances" which retard the bleaching of flax, jute and similar fibres

may be removed by "scalding" the fibres in a solution of an alkali or alkaline earth sulphide (e.g., a 5 to 15 per cent. sodium sulphide solution) for about half an hour; fibres are then washed and rinsed in a dilute acid solution and the process repeated twice or thrice; the bleaching is then proceeded with in the usual way. —T. F. B.

Warps: Method of and Apparatus for Printing

G. Morton, Carlisle. Eng. Pat. 9341, April 23, 1904. The invention relates to the printing of warp yarn the production of figured woven fabrics such as Laces or tapestry carpets. The warps are fed through a beam, below which are a series of colour blocks with a corresponding series of type blocks above, type blocks, which are controlled by Jacquard or mechanism, press the yarn on to the colour pads; blocks are mounted on a suitable frame which oscillates up and down. At each downward stroke certain type blocks are rendered inoperative by tension of harness threads controlled by the Jacquard. The colour pads are connected with drains or troughs which automatically feed with the colour mixture. —E. F.

Discharges on Dyed Materials: Production of Coloured

UNITED STATES PATENTS.

Felt Cloth: Process of Making —. J. B. Lamm, Philadelphia, Pa., U.S.A. U.S. Pat. 789,098, May 2, 1905.

THE materials of which the felt is to be made, after cutting up into "short length fibres," are partially reduced together, dyed, and thoroughly dried. They are then saturated with warm oil, after which the felting is completed. The fabrics produced, while they are still impregnated with oil, are finally "finished" with dry paper, and, if desired, are pressed by means of hot rollers. The dyeing and felting, instead of being performed separately, as described, may be effected simultaneously, while the materials are saturated with oil. —E. B.

Mercerising, &c.: Machine for —. W. H. Cronin and W. Horrocks, Radcliffe, England. U.S. Pat. 789,260, May 9, 1905.

Warps: Apparatus for Printing — on Printing Drums. F. Schmidt, Oberschöneweide, Germany. U.S. Pat. 789,068, May 2, 1905.

A COMBINATION of the following apparatus is claimed: A printing-drum with crown-teeth arranged at one end of it; a pattern-drum of smaller diameter than the printing-drum; a shaft carrying (i.) a toothed wheel engaging with the crown-teeth on the printing-drum, (ii.) a second wheel engaging with gear on the pattern-drum, and (iii.) a third wheel gearing with a wheel on a second shaft on which is fixed an operating wheel; an indicating device arranged near the printing-drum, the pattern-drum and the indicator are movable relatively to each other, their movement imparting, through the transmitting gear, a corresponding movement to the printing-drum. —E. B.

Warps: Double Printing-Drum for Printing —. F. Schmidt, Oberschöneweide, Germany. U.S. Pat. 789,069, May 2, 1905.

CLAIM is made for apparatus for printing yarns in the

carps, comprising two printing-drums of different diameters bearing crown wheels, the drums being connected by a pattern drum; a transmitting device for giving to each of the printing-drums, when in operation, the same angular velocity; an indicating device, arranged between the pattern-drum and the printing-drums, arranged to use the movement of the pattern-drum to be transmitted to each of the printing-drums.—E. B.

FRENCH PATENTS.

Artificial ——. L. Bergier. Fr. Pat. 349,131, March 10, 1904.

Wool is scoured, treated with a boiling 2 per cent. solution of hydrochloric acid, dried at 120°–130° C., and then in a mixture of 30 litres of nitric acid (40° B.) and 50 litres of sulphuric acid (66° B.) per 2 kilos. of wool. After 20–25 minutes the nitrocellulose is removed, washed with water and then with alcohol, and dried in ether-alcohol (3:1); the pyroxylin is then led into threads in the usual way, and these are dyed by immersion for some hours in a solution of stannous chloride at a temperature of 60° C., washed with water and then with dilute hydrochloric acid, again washed with water, and dried.—T. E. B.

Centrifugal Machine with Circulation of Liquid [for Textiles]. J. Selwig. Fr. Pat. 348,673, Nov. 16, 1904.

This machine is designed for treating textile and other materials with a circulating liquid, the cage being run at high speed, and afterwards for draining them by running the cage at high speed after the liquid has been withdrawn. To this object a small annular space is left between the perforated central cone of the cage and the main support supporting the driving spindle, and communication is established between this space and the fixed casing of the machine, either by pipes or by channels at the bottom of the casing. When the machine is run, the centrifugal force produces a depression in the surface of the liquid nearest the central cone of the cage, and consequently the liquid in the annular space flows through the perforations into the cage, and is continuously replaced by the return flow through the channels communicating with the outer casing.—C. S.

Washing Materials; Machine for Washing and Rinsing ——. F. Bernhardt. Fr. Pat. 348,784, Dec. 12, 1904.

This machine consists of a long trough with a perforated bottom placed close to the surface of the liquid. The bottom consists of a series of shallow perforated plates, which run in a longitudinal direction, and are on one side to the surface of the liquid. Each curved plate is joined to the next by a short plate which is not perforated and may be either horizontal, or corrugated in any suitable manner so as to offer resistance to the movement of material lying on it. These plates are very close to the surface of the liquid. Above each plate is a series of spraying pipes through which a strong current of water or washing liquid is forced on to the material lying on the plates, the closeness of which to the surface of the liquid prevents the material being submerged, and so escaping from the action of the sprays. The material is fed in at one end of the machine and moves from one plate to the next by an arrangement of rollers which follow the curved bottoms of the intermediate spaces. The liquid can be circulated by means of a pump.—A. B. S.

Washing Machines Suitable for Treating ——. [with Claims]. J. W. Fries. Fr. Pat. 349,145, Dec. 12, 1904.

Eng. Pat. 26,084 of 1904; this J., 1905, 273.—T. E. B.

Scouring Loose ——. by the aid of Electricity. J. M. Baudot. Fr. Pat. 349,042, Dec. 13, 1904.

Wool, in the loose state, is placed upon an endless, travelling apron, and thus conveyed, between this and a second travelling apron, through a wood or slate scouring-tank. The lower apron is composed of metal bars, placed parallel to another upon two endless chains. This constitutes

an electrode, being connected with a terminal on a supply of electric current; a curved, perforated metal plate, fixed a little below the surface of the scouring tank, forms the second electrode, and the upper apron, which is composed of pervious textile material, acting as a diaphragm. Hot water is supplied to the bath by a steam pipe. At the termination of the operation of scouring, several minutes' action is required to effect the removal of the fatty, &c., matters from the wool during its passage through the tank, but, as the potash and other salts extracted from the wool accumulate, the action becomes more rapid. The heavier matters pass to the bottom of the bath; the fatty matters rise to its surface. The valuable constituents of the unscoured wool are afterwards recovered.—E. B.

Embossing or Printing of Fabrics; Blocks for ——. E. Roudet. Fr. Pat. 348,836 Feb. 21, 1904.

The printing block consists of a rectangular frame one side of which is adjustable by means of screws. This frame is filled with a number of cylindrical "pins" of the same length, made of steel or other material. These are packed parallel in the frame so that only their ends project. By loosening the screws, any required number of these can be made to project beyond the surface of the remainder, and so form any required pattern when used for embossing or printing.—A. B. S.

Fabrics, Papers, Leathers, &c.; Decoration of ——. L. Guetton-Dangon. First Addition dated Feb. 27, 1904, to Fr. Pat. 348,837, Feb. 21, 1904.

INSTEAD of mounting the "rubbers" firmly on a table so as to always give a plane rubbing surface, each of the separate rubbers is pressed into the engraving by means of a spring, and so gives a more delicate design.—A. B. S.

Fabrics, Papers, Leather, &c.; Ornamentation of ——. L. Guetton-Dangon. Fr. Pat. 348,977, Feb. 29, 1904.

A HOLLOW cylinder is employed which is perforated with the required design. Inside this are placed rubbers, or metallic brushes, preferably heated, which are pressed by means of springs so that they act through the perforations to produce effects on the surface of the material, which is passed over the cylinder. The fabric can be on another cylinder or on a plane surface and both the fabric and the pattern cylinder can be given suitable movements so as to obtain the required effects on the fabric.—A. B. S.

Tissues, Process and Apparatus [Blocks] for Printing ——. F. Rose. Fr. Pat. 349,138, Dec. 8, 1904.

A PRINTING-block is prepared in two or more pieces which fit together. A portion of the design is engraved upon one of the pieces, in which holes are arranged, the rest of the design being engraved upon raised parts of the other pieces, which fit into the openings in the first piece in such a manner that the printing surface of the whole block is in one plane. Each piece is further provided with an auxiliary colouring block, bearing projections or openings, as the case may be, upon which it is placed during the operations of applying colour to it, and removing the excess of the latter from it. After detaching the auxiliary blocks, the various parts of the printing block, which may conveniently be supplied with different colours, are fitted together to form a composite block, with which the printing of tissues is then accomplished in the usual manner.—E. B.

Textile Materials; Preparation [from Starch and Gluten] for Finishing ——. Erste Triester Rischschl.-Fabriks-Aet.-Ges. Fr. Pat. 349,074, Dec. 17, 1904.

RICE flour rich in gluten, or a mixture of ordinary rice flour with a sufficient quantity of gluten to bring the total content in the latter up to 8 per cent., is gently heated with steam to soften it, and is then completely cooled. It is then treated for an hour with an alkali, e.g., ammonium carbonate (one part in a 5 per cent. solution, for 20 parts of the proteid matter) to dissolve the gluten. Lactic acid (two parts of the anhydride for five parts of the proteid) is next added. After being well stirred, the mass is evaporated to dryness, the dry product ground to powder

and starch. The lactic acid may be produced by the decomposition of a portion of the starch. Acetic acid may be employed instead of it.—E. B.

GERMAN PATENT.

Dye-stuffs, Solubility: Process for Producing — in the *Fabric*, Act of S. 1. Anilinfabr. Ger. Pat. 178,328, March 14, 1900.

Blue or black shades may be obtained on fibres by printing or padding the material with a mixture of an alkali polysulphide and an aminohydroxy, nitrohydroxy, or nitroaminohydroxy derivative of the benzene series, and then steaming. The shades obtained are stated to be clear and fast; it is also stated that the fibres are not weakened. *p*-Aminophenol, dinitrophenol, and nitroaminohydroxydiphenylamine give black shades by this method, whilst the indophenol from *p*-aminodimethyl-aniline and phenol, gives blue shades.—T. E. B.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Tetrathionates: Reduction of — to Sulphites by Arsenite and Stannite. A. Gutmann. Ber., 1905, 38, 1728—1734.

WEINLAND and the author have previously shown (this J., 1899, 80) that by the action of sodium arsenite on sodium thiosulphate, one atom of sulphur is withdrawn from the latter, whereby it is converted into sulphite, whilst, at the same time, sodium monosulphoxyarsenate is formed from the arsenite.

The behaviour of sodium tetrathionate to sodium arsenite and sodium stannite in alkaline solution, has now been investigated. It was found that by the action of sodium arsenite on sodium tetrathionate in sodium hydroxide solution, tertiary sodium arsenate is always formed, in addition to sodium sulphite and monosulphoxyarsenate. No formation of sodium sulphate, sulpharsenate or disulphoxyarsenate ($\text{Na}_2\text{AsS}_2\text{O}_6$) could be detected. Quantitative experiments showed that the reaction proceeds according to the equation:—

This behaviour of sodium thiosulphate and tetrathionate is not in accord with the formulae generally accepted for these compounds, viz.,

but points rather to the formulae

respectively. Sodium stannite reduces sodium tetrathionate in a similar manner to sodium arsenite, sodium sulphite, sulphostannate and stannate being produced.

—A. S.

Calcium Sulphate in Ammonium Sulphate Solution. E. C. Sullivan. J. Amer. Chem. Soc., 1905, 27, 529—539.

THE author determined the solubility of calcium sulphate in solutions of ammonium sulphate at 25° C. The results obtained are shown in the following table:—

Concentration of Ammonium Sulphate.	Weight of Calcium Sulphate Dissolved.	Concentration of Ammonium Sulphate.	Weight of Calcium Sulphate Dissolved.
Gm.-mols. per litre.	Grms. per 100 c.c.	Gm.-mols. per litre.	Grms. per 100 c.c.
0.00	0.2083	0.06250	0.14
0.0009766	0.2043	0.1250	0.141
0.001953	0.1996	0.2500	0.16
0.007812	0.1807	0.7500	0.23
0.01561	0.1658	1.5000	0.33
0.03125	0.1540	3.0000	0.49

The curve is similar to that found by Cameron and Seidell (this J., 1902, 549; 1904, 865) for the solubility of calcium sulphate in sodium sulphate solution.—A. S.

Calcium Sulphate: Solubility of — in Solutions of Salts. F. K. Cameron and B. E. Brown. J. of Chem., 1905, 9, 210—215. Chem. Centr., 1905, 1, 62.

THE solubility of calcium sulphate in solutions of ammonium chloride and nitrate at 25° C. was determined. The maximum solubility was observed in both cases, 10.88 grms. of calcium sulphate in a solution containing 210 grms. of ammonium chloride per litre, and 12.20 in one containing 750 grms. of ammonium nitrate per litre. The solubility curve is tolerably steep in the vicinity of the maximum point in the case of ammonium chloride, very flat in the case of ammonium nitrate. The solubility of calcium sulphate in saturated solutions of these salts was also determined, the following results being obtained:—

Salt.	Grms. of Salt per Litre.	Grms. of Calcium Sulphate per Litre.
Sodium chloride	318.3	5.52
Sodium nitrate	668.4	7.16
Sodium sulphate	254.6	2.58
Magnesium chloride ..	476.5	1.09
Magnesium nitrate ...	615.1	15.86
Ammonium chloride ...	375.3	7.38
Ammonium nitrate ..	—	7.55

Calcium sulphate is insoluble in saturated solutions of calcium chloride and nitrate. (See also this J., 1904, 865.)—A. S.

Lead Ferrocyanide: Action of Oxalic Acid on A. Leuba. Ann. Chim. anal. appl., 1905, 10, 143. Chem. Centr., 1905, 1, 1463.

IF lead ferrocyanide be boiled for two to three hours with oxalic acid solution, there are produced ferrous oxalate which forms with the excess of oxalic acid, a golden-brown solution, a white precipitate of lead oxalate, a precipitate of Prussian blue, and hydrocyanic acid. The formation of Prussian blue is due to a secondary reaction, as is shown in the following equations:—

When boiled with sulphuric acid, lead ferrocyanide is decomposed, in an analogous manner, into lead sulphate, Prussian blue, and hydrocyanic acid.—A. S.

Mercuric Iodide: Action of — on Sulphuric Acid and on the Mercuric Sulphates. A. Ditte. Comptes Rend., 1905, 140, 1162—1167.

THE author has in 1878 demonstrated the existence of the volatile compounds HgSO_4 , HCl and HgSO_4 , but no analogous iodine compound is formed by the reaction of hydriodic acid on mercuric sulphate or of sulphuric acid on mercuric iodide. When the latter two compounds are heated together, mercuric iodide slowly sublimes, and at a higher temperature some iodine is formed and also sublimes, while the liquid after cooling deposits groups of white silky needles.

iodine is produced, according to the author, by the action on the iodide of sulphur trioxide resulting from partial dissociation of the sulphuric acid: $\text{HgI}_2 + \text{H}_2\text{SO}_4 = \text{HgSO}_4 + \text{SO}_2 + \text{I}_2$. No dissociation of mercuric iodide occurs at the temperature of the experiment. On adding mercuric iodide to Nordhausen sulphuric acid, a liquid is at once formed, which, on heating, evolves sulphur dioxide. On continued heating, the colour gradually disappears, and the liquid on cooling deposits mercuric sulphate, and, after some time, a crystalline of $\text{HgI}_2 \cdot 3\text{HgSO}_4$. A number of compounds of mercuric iodide with normal and basic mercuric sulphates are obtained by digesting mercuric iodide with sulphuric acid of various strengths in which has been dissolved mercuric sulphate as it can take up.—J. T. D.

Solubility of — in Benzyl Chloride. J. Ruski. J. russ. phys.-chem. Ges., 1905, 37, 92—93. Chem. Centr., 1905, 1, 1207—1208.

Mercury melts in benzyl chloride at 106.8°C , and forms two layers, the upper one a solution of sulphur in benzyl chloride, and the lower one a solution of benzyl chloride in mercury. Above 124.2°C the two liquids are miscible in all proportions. The results of the solubility determinations were as follows:—

Temperature of solution	0°	17°	35°	66.1°	68.3°	78°
of sulphur per 100 grms. of solution (upper layer)	0.99	1.78	2.57	3.64	6.15	3.88
of sulphur per 100 grms. of solution (upper layer)	99.1°	109.6°	114.6°	118.8°	121.4°	130°
of sulphur per 100 grms. of solution (lower layer)	19.89	—	—	37.29	40.04	49.71
	—	90.62	87.99	—	85.02	80.07

Sulphuric Anhydride and Sulphuric Acid Vapours; Process of Recovering —, from Gases. M. Schroeder, Berlin; Germany, Assignor to New Jersey Zinc Co., New York. U. S. Pat. 789,634, May 9, 1905.

Sulphuric acid mists or fogs are passed, with the accompanying gases, through a body of finely-divided material, resting on a perforated support in a horizontal cylinder. The material is saturated with sulphuric acid, and absorbs any free sulphuric anhydride present in such gases.—E. S.

—A. S.

Sulphur-Burner. H. Blumenberg, jun., Daggett, Col. U. S. Pat. 788,512, May 2, 1905.

The burner, which is long relatively to its diameter, has a flat horizontal floor supported by angle-irons, an arched top, an air-supply pipe, a normal and an auxiliary discharge pipe, the latter valved, and a charging trap having a quick-opening door. There is a door at one end of the burner admitting to a cleaning trap. (Compare U. S. Pat. 734,397 of 1903; this J., 1903, 950.)—E. S.

Perborate; Process of Making [Alkali] —. O. Liebknecht, Frankfurt-on-the-Maine, Germany, Assignor to Roessler and Hasslacher Chemical Co., New York. U. S. Pat. 788,780, May 2, 1905.

See Eng. Pat. 22,004 of 1904; this J., 1905, 197.—T. F. B.

Copper Sulphate; Process of Making —. A. L. Walker, New York. U. S. Pat. 788,862, May 2, 1905.

COPPER frames, containing "shot copper," are suspended over a vat into which sulphuric acid flows continuously, in such a manner that they can be successively immersed and withdrawn, at frequent intervals, by mechanical means. The vat is heated, and as the heavy crystallisable solution of the sulphate accumulates in the lower part, it is allowed to run off in proportion as acid is admitted to the top of the tank.—E. S.

Potassium Salts; Process of Making —. A. J. Swayze, Danville, N.J. U. S. Pat. 789,074, May 2, 1905.

A MIXTURE of crushed potash felspar, gypsum and carbon (or other reducing agent), is heated to fusion in a closed vessel, and the "potassium products" volatilised, are collected in water.—E. S.

Phosphate Rock; Process of Treating —. E. J. Machalske, Brooklyn, N.Y., Assignor to F. Dartington, Great Barrington, Mass. U. S. Pat. 789,438, May 9, 1905.

A MIXTURE of an ore containing calcium phosphate, with sodium chloride and an excess of carbon, is heated, electrically or otherwise, to a high temperature, to produce a chloride of phosphorus, and carbides of calcium and of sodium.—E. S.

Phosphate Rock; Process of Treating — and Producing Compounds of Phosphorus and Nitrogen. E. J. Machalske, Brooklyn, N.Y., Assignor to E. Barrington, Great Barrington, Mass. U.S. Pat. 789,439, May 9, 1905.

A MIXTURE of an ore containing calcium phosphate, with an alkali-metal chloride and carbon, is subjected to a high temperature, electrically or otherwise, in the presence of nitrogen, to produce a chloride of phosphorus and cyanamide of calcium and of an alkali metal. The cyanamide is treated with water to produce ammonia and a carbonate of calcium and of the alkali metal. —E. S.

Phosphate Rock; Process of Treating — and Producing Phosphorus Chlorides and Alkali Metal Compounds. E. J. Machalske, Brooklyn, N.Y., Assignor to E. Barrington, Great Barrington, Mass. U.S. Pat. 789,440, May 9, 1905.

ONE portion of the cyanamides of calcium and of an alkali metal obtained together with a chloride of phosphorus, as described in the preceding abstract, is treated with water for the production of the carbonates of calcium and of the alkali metal, and the remaining portion of the cyanamides is mixed with the alkali metal carbonate so obtained, and the mixture is heated to obtain the cyanide. —E. S.

Chlorides and Peroxides; [Electricity] Manufacture of —. M. Guerin, Geneva, Switzerland. U.S. Pat. 788,631, May 2, 1905.

AN alkali chloride solution is electrolysed to form a chloride and perchlorate, and the alkali formed is "neutralised" by the addition of lead chloride. The lead hydroxide precipitated is transformed into peroxide. —E. S.

Alkaline Fluxes; Process of Making —. J. A. Reich, Vienna, Austria-Hungary. U.S. Pat. 789,671, May 9, 1905.

THE process for recovering "alkaline finesilicates" from the residues formed by the conversion of "alkaline silicofluoride" into alkali by means of lime, consists "in boiling the said residues with substantially as much lime as that necessary for the complete conversion of the alkaline silicofluoride, said boiling being effected during the production of the alkali itself for the sake of obtaining a more intimate mixing of the residues with the lime, treating the residues resulting from said boiling with an acid, and precipitating therefrom the alkaline finesilicate by means of a salt of the desired alkali." —E. S.

GERMAN PATENTS.

Dissolving Salts; Centrifugal Apparatus for —, with Circulation of the Solvent Liquid. Brandt and Fude. Ger. Pat. 156,705, Dec. 11, 1902.

THE apparatus consists of a rotating annular perforated drum containing the salt, arranged in a closed chamber into which the solvent liquid is fed. Between the outer wall of the perforated drum and the wall of the outer chamber is disposed an annular stationary division plate provided with suitable openings, and it is claimed that this plate causes an intimate mixing of the solution ejected from the drum in a radial direction by the centrifugal force with the liquid contained in the space enclosed by the drum, whereby rapid and complete saturation of the solvent liquid is effected. —A. S.

Silicides, Borides, Aluminides, and analogous Compounds; Process for the Preparation of —. E. Jüngst and R. Mewes. Ger. Pat. 157,615, Feb. 4, 1902.

REFRACTORY halogen compounds of metals are heated in the electric furnace with elements, the halogen compounds of which are more readily volatile and which can be formed by direct union of the element and halogen with evolution of heat; suitable elements are silicon, boron, aluminium, iron, chromium, tin, and phosphorus. For example, calcium ferride, CaFe , can be obtained by subjecting a mixture of nearly equal parts of calcium chloride and iron powder to a white heat in a closed electric furnace connected

with a condensing chamber. When the mixture of the calcium chloride decomposes, ferrous chloride passes over and collects in the condensing chamber, whilst calcium ferride is tapped off from the bottom of the furnace. —A. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Fused Silica Tubes [Quartz Glass]; Permeability of —. M. Berthelot. Comptes rend., 1905, 140, 1159—1162.

TUBES of fused silica are not permeable by hydrogen at the ordinary temperature, even after many days' exposure; at $600^{\circ}\text{--}800^{\circ}\text{C}$. the transpiration, if it exists at all, is rapid enough to be sensible after an hour's exposure; but at 1300°C . it is considerable and rapid. The transpiration of hydrochloric acid gas is not sensible till 1400°C ., that of carbon dioxide is barely so at 1400°C . Nitrogen does not sensibly permeate the tubes at 800°C ., possibly it begins to do so at 1000°C ., but does so so slowly at $1300^{\circ}\text{--}1400^{\circ}\text{C}$., though very much less rapidly than hydrogen at the same temperature. The transpiration of oxygen is somewhat more rapid than that of nitrogen. A volume of air (1.97 c.c. at normal temperature and pressure) was introduced into a tube of 5.35 c.c. capacity, which was sealed and exposed for an hour to a temperature of 1400°C .; though the capacity of the tube had increased (the softened quartz being blown out by the pressure of the hot gases) to 6.50 c.c., the contained gas had a volume at normal conditions of only 1.58 c.c., and contained 17.7 per cent. of oxygen instead of the original 21 per cent. About one-sixth of the initial volume of nitrogen and about one-third of the initial volume of oxygen disappeared. The ratio here is very similar to that in which the gases of the atmosphere dissolve in water. —J. D.

Glass Vessels; Permeability of —. Berthelot. Comptes rend., 1905, 140, 1286—1292.

WHEN vessels of glass or silica are heated to a temperature at which the walls are softened, the glass acquires the properties of a colloidal solid, such as caoutchouc or elastic membranes. The gas enclosed in the heater then passes through the softened glass by diffusion, and air passes inwards. The permeability of the glass is as soon as the temperature is lowered below the softening point. Experiments with closed tubes of different thicknesses of glass, and containing hydrogen, oxygen and carbon monoxide, have proved that the gaseous interchange follows the laws of diffusion through permeable membranes. —J. D.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Calcium Silicates, Magnesium Silicates and Calcium-Aluminium Silicates [Lime-Sandstone]. E. Thier. Oesterr. Chem.-Zeit., 1905, 8, 145—148. Chem. Abstr., 1905, 1, 1361—1362.

THE author has attempted to elucidate the conditions occurring in the manufacture of lime-sandstone, and to determine the chemical composition of the silica, which the strength of the product is due. Lime in the form of pure calcium oxide, and silica in the form of quartz, chemically pure amorphous silicic acid and infusorial earth, were heated together in a steam boiler under a maximum pressure of 25 atmospheres, and in a small autoclave under a pressure of 200 atmospheres. It was observed that if the lime is mixed in the hydrothermal condition with silica, the strength of the product is less than when the hydration of the lime takes place after the heating. The higher the sp. gr. of the silica used, the greater the strength of the product, except when quartz is employed, this form of silica reacting less readily than other silicates. The strength of the sandstone increases with the fineness of the particles of the constituents, and the cement of the blocks or bricks after moulding is of

rance. The best results are obtained by heating moulded bricks for half an hour at 100° C., and then letting them to rest until the lime is completely hydrated. The maximum strength is, in general, attained by heating at a pressure for 6-8 hours. An increase of the pressure to 12-15 atmospheres has no noteworthy effect on the strength of the product. The sandstone obtained from nature, in which the proportions of lime and silica were 1, had the greatest tensile strength. At a pressure of 10 atmospheres it is not possible to effect the quantitative conversion of lime and silica, but by increasing the pressure to 200 atmospheres, and with a mixture of equal proportions of lime and silica, free silica could be detected in the product in very small quantities, and free lime only up to 1 per cent. The silicate formed in the lime-sandstone has the composition $\text{CaO} \cdot \text{SiO}_2$, 2.34Aq., but the stage of water in the product varies slightly. In plates of the sandstone, each grain of silica appears surrounded by a darker, finely-granular portion which contains the hydrosilicate.

Hydrosilica, used in its heavy form, combines with lime even at a pressure of 8-10 atmospheres. The silicate formed, has the composition $\text{MgO} \cdot \text{SiO}_2$, 2.3Aq., unlike the corresponding calcium silicate, it is not only resistant to frost.

Mixtures of silica and lime with alumina and aluminium oxide were also exposed to the action of steam, but the blocks disintegrated, and only a very small quantity of silica was combined. Mixtures of lime, silica, and kaolin gave better results. By repeatedly exposing the mixture to the action of steam, after grinding, the reaction was effected, especially with a mixture of parts of kaolin, 80 of silica, and 20 of lime. The silicate formed had the composition: $\text{CaAl}_2\text{Si}_2\text{O}_8$, 1, i.e., nearly the same as that of stilbite, $\text{Si}_6\text{O}_{16} \cdot 5\text{H}_2\text{O}$.—A. S.

Sand Bricks; Effect of Iron Pyrites on Strength — H. Gerlings, J. Chem. Metall. and Min. of S. Africa, 1905, 5, 229-230.

The presence of iron pyrites in the sand would have no effect beyond changing the colour to a yellowish or reddish and the brick would require a little more lime to the same resistance to crushing. Ferric oxide reacts with lime only, if at all, with silica, during the steaming of the sand and may be considered inert save for its colouring effect. Five lime-sand bricks were heated rapidly to the m. pt. of Seger cone 6 (about 1300° C.), and taken out while warm. They kept their shape, were white and semi-vitreous, and had not shrunk.

These contained 10 per cent. of lime, also 10 per cent. of kaolin and of felspar mixture. Five other bricks containing only 5 per cent. of lime, were heated to the pt. of cone 8 (about 1300° C.); in this case the bricks shrank and felspar exploded and splintered, whilst the bricks containing only pure quartz sand and lime were not but became white, and also more porous, owing to the action of combined water.—J. T. D.

X.—METALLURGY.

Furnace Process; Potassium Cyanide and the Nitrogen Reactions in the — H. Braune, Chem. Z. Berg. u. Hüttenw. 1905, 53, 153. Chem.-Zeit., 1905, 29, Rep. 142.

The reduction of an inferior material in the puddling process, even when the best pig iron of good analysis and

fracture is used, has been attributed to the presence of nitrogen in the blast furnace. The carbon content of the iron is mainly due to the formation of potassium cyanide and similar products which owe their origin to the basic charges together with high pressure and temperature of the air blast. Iron and free nitrogen do not combine directly at any temperature, but if the nitrogen is combined, as in potassium cyanide, combination with the iron can take place very easily, the reaction being accelerated by rising temperature.

Iron oxide is also not attacked by free nitrogen, but it readily reacts with potassium cyanide as follows:—

The potassium cyanate takes up oxygen to form carbonate, which rises to the furnace mouth and is found in the fines and "downcomers."

If bisilicate charges be used, and the iron be blown with the blast heated to 150-200° C., only traces of nitrogen are found in the resulting product.

To remove nitrogen from steel attempts have been made to use titanium-thermit.—R. J. S.

Steel Process in Fired Furnaces; Continuous — S. Surzycki. Iron and Steel Inst. May, 1905. [Advance Proofs.]

The process is based on the Talbot process, but it can be carried out in any fixed furnace of not less than 25 tons capacity. It mainly depends on the arrangement of two or more tapping holes placed one above the other, but not in a vertical line. These are arranged in a cast-iron plate, lined with magnesite bricks and stamped dolomite; they give no trouble since they can neither slip, nor sink, nor be corroded. The tapping holes lead into a double launder; when the molten bath has sunk to the lower hole, it is agitated by means of a rabble so as to clear the hole from metal. Some dry burnt dolomite is thrown in on the charging side, the last drainings are removed from the hole and it is then closed from the tapping side. The whole operation lasts a few minutes only, the hearth remains sound for months, only the slag-line and, in a less degree, the blocks needing repairs. The extent and useful effect of the method as employed at the Czenstochowa works in Poland are shown in a series of tables.—J. H. C.

Steel, Hardened; Structure of — H. W. Kurbatow. J. russ. phys.-chem. Ges., 1905, 37, 169-189. Chem. Centr., 1905, 1, 1441. (See this J., 1905, 334.)

EXPERIMENTS with a steel containing 1.9 per cent. of carbon, 0.02 per cent. of sulphur and phosphorus, and 0.02 per cent. of manganese, showed that during the annealing of the hardened steel at low temperatures, the *martensite* and *austenite* are converted into a network of lamellae of *cementite* surrounded by *troostite*. By annealing at temperatures above 350° C., the *cementite* and *troostite* are converted into *cementite* and *ferrite*. The author concludes from the results of his experiments that the only true chemical individuals present in steel are *cementite* and α -, β -, γ -, and δ -*ferrite*; all other phases which can be recognised under the microscope must be regarded as solid solutions. The names *troostite* and *sorbite* are generally given to those structural elements which acquire a dark colour on etching with acids, but as this dark colour can be explained only by the separation of fine particles of dissolved carbon, *troostite* and *sorbite* must be regarded as solid solutions of carbon in different kinds of *ferrite*. The structural elements which remain light-coloured on etching, and which have been named *martensite* and *austenite* are considered by the author to consist of solid solutions of *cementite* in γ - and δ -*ferrite* respectively.—A. S.

Steel; Studies on the Cooling during the Quenching of — P. Lejeune. Bull. Soc. d'Enseign., 1905, 107, Rev. de Metall., 299-311.

THE results of the author's experiments, which were carried out in a different manner to those of Le Chatelier, confirm the conclusions drawn by the latter (see this J., 1904, 1030).—A. S.

Aluminium Steels. L. Guillet. Bull. Soc. d'Encour., 1905, 107, Rev. de Metall., 312-327.

THE author's experiments were made on two series of steels containing about 0.150 and 0.750 per cent. of carbon respectively, the percentage of aluminium in the steels ranging from 0 to 15. It was found that small quantities of aluminium have practically no influence on the mechanical properties of iron, but when the amount of aluminium is greater than 2-3 per cent., the metal becomes very brittle. No compounds of the two metals are formed; the aluminium dissolves in the iron, and, it is stated, prevents the development of the *pilrite* crystals, causing this constituent to separate in a special granular form, to which the brittleness of certain of the steels may be due. The solution of aluminium in iron does not dissolve carbon, but graphite is not separated as would have been expected. When the aluminium and carbon are present in sufficient quantities, *cementite* is found in the steel, although in all of the specimens examined, the amount of carbon was much less than 0.85 per cent. On quenching aluminium steel, *martensite* is produced only in those parts where *pilrite* was previously present. It is noted that steels containing a small quantity of aluminium show only a very slight hysteresis, and are thus specially suitable for electrical machines, &c. (See also this J., 1899, 1131.)

—A. S.

Gold: Precipitation of — from Cyanide Solutions. W. J. Sharwood. Eng. and Mining J., 1905, 79, 752-754.

THE author describes and compares the various methods for the precipitation of gold from cyanide solutions. In the following table are given some results obtained in the case of plants where zinc shavings and dust are used:—

Material Treated at Plant.	Form of Zinc used.	Average Strength of Solution.	Tons of Solution Precipitated by 1 lb. of Zinc.	Percentage of Zinc dissolved.	Troy ounces Precipitated by of Zinc.		
					Gold.	Silver.	Copper.
		Per cent. KCN.					
Sand, gold and silver	shaving	0.32	1.5	84.0	0.31	0.56	
Slime, gold and silver	shaving	0.04	5.0	37.0	0.25	0.5	
Rich gold ore	shaving	0.5	1.1	40.0	1.10	0.10	
Mixed tailing, gold	shaving	0.1	3.3	60.0	0.70	0.01	
Sand, gold and silver	shaving	0.2	3.2	79.0	0.16	3.19	
Mixed tailing, gold and silver	dust	0.1	2.0	30.0	0.35	0.70	
Low-grade sand, gold	dust	0.06	5.0	84.0	0.76	0.30	
Mixed tailing, gold and silver	dust	0.08	3.5	60.0	0.31	2.08	
Low-grade slime, gold and silver ..	dust	0.033	5.0	66.0	0.12	0.83	

A comparison of different methods of precipitation with a solution containing about 2.5 dols. of gold and 0.2 dol. of silver per ton, together with about 0.015 per cent. of copper and 0.05 per cent. of free cyanide, gave the following results:—

Method of Precipitation.	Percentage of Contents Precipitated.		
	Gold.	Silver.	Copper.
Saturation with hydrogen sulphide	2	97	3
Acidulation	65	90	75
Electrolysis for 24 hours	100	100	100
Agitation with zinc dust for 15 mins.	25	60	3
Agitation with zinc dust and filter-pressing.	94	97	4

The author considers that the method of precipitating by zinc shavings is by far the best for small or temporary plants, but that in the case of installations designed for the treatment of 100 tons or more of solution per day, or likely to be in use for several years, the electrolytic and zinc dust processes must be taken into account.—A. S.

Gold. Re-precipitation of — from Cyanide Solutions, and Absorption of Gold by a Wooden Leaching Vat. A. N. Mackay. Inst. of Min. and Met., May 18, 1905. [Advance Proofs.]

1. A vat of pyritic concentrates from a Willfley table,

carrying about 30 per cent. of iron disulphide, and about 10 oz. of gold per ton had been put under treatment, and thus reduced to a value of 8 oz. of gold per ton. It was sampled from top to bottom and assayed with the following results:—

	Oz.	Dwt.	Gr.
Sample of top foot	0	13	0
Sample of middle foot	2	2	0
Sample of bottom foot	17	8	0
Sample from top to bottom	6	2	0

The gold extracted from the upper part had thus been reprecipitated in the lower.

Another "face" was then sampled at each 6 inch depth, giving results as under:—

	Oz.	Dwt.	Gr.
Top 0 inches	0	11	0
Next 6 inches	0	17	12
Next 6 inches	1	0	0
Next 6 inches	5	8	0
Next 6 inches	16	2	0
Bottom 6 inches	33	0	0
From top to bottom	9	6	0

In another case, re-precipitation being suspected, sludge from a 0.20 per cent. cyanide solution containing about 0.04 per cent. of potassium hydrate per ton filtered, sampled, and assayed at regular intervals shown below:—

Time.	Slime.			Solution.		
	Oz.	Dwt.	Gr.	Oz.	Dwt.	Gr.
2 p.m.	0	4	0	0	8	
6 p.m.	0	4	18	0	2	
10 p.m.	0	5	12	0	1	
8 a.m.	0	7	0		trace	
5 p.m.	0	7	0		trace	

Complete precipitation had therefore taken place in about 18 hours. When a solution was employed containing only 0.01 per cent. of alkalinity no re-precipitation occurred.

2. A wooden leaching vat had been used for treating by percolation the "sands" of a roasted sulphate ore. When dismantled, the wood, cocoanut matting, and Hessian, were cleaned and separately incinerated, the resulting ashes, calculated back to the ton of original substance, yielded on assay:—

	Oz.	Dwt.	Gr.
Wood	12	8	0
Hessian	3	12	0
Matting	5	14	0

—J. J. C.

Base Bullion: Refining of — W. Dowling. J. Inst. Min. and Met. Soc. of S. Africa, 1905, 5, 224-25.

THE base bullion referred to was obtained by the amalgamation of slags, produced by the crucible smelting of zinc-gold slimes. The chief impurities were zinc and copper. After retorting, the metal was broken up as much as possible, mixed with (for every 100 parts) 1 part of potassium permanganate, 35 of calcined borax and 25 of sand, and melted in a clay-lined crucible. When fused and tranquil, the slag was thickened and skimmed off, and the metal granulated. This treatment was repeated five times, the permanganate being increased at the third fusion to 20 parts. The 432 oz. of base bullion testing 28 per cent. of gold became at the end

ing, testing 79 per cent. This was then mixed with bullion to bring the average above 80 per cent.; had not been done a sixth fusion would have been necessary, bringing the bullion up to the standard requirement, a minimum fineness of 80 per cent. The granulation was by resting the crucible on a table about 3 ft. high, pouring in a stream not thicker than a lead pencil into a 12 in. deep, which was kept in constant rotation.

—J. T. D.

er containing Oxygen: Microstructure of —. Giraud. Bull. Soc. d'Encour., 1905, 107, Rev. de lall., 297—298.

er and cuprous oxide in the molten condition are ally soluble, and on cooling give, when the copper excess, a mixture of a eutectic containing 3.5 per cent. of cuprous oxide, and the excess of copper. In mixtures containing an excess of cuprous oxide, however, especially on solidification take place slowly, mixtures of the metal and of copper without the eutectic, or of copper, cuprous oxide and the eutectic are frequently obtained instead of the expected mixture of cuprous oxide and metal. This apparent deviation from the laws of solidification of alloys is explained as follows by the author: At the beginning of the solidification, crystals of cuprous oxide separate until the molten metal attains the composition of the eutectic, at which point copper also should separate. The copper, however, remains in a state of superfusion, and the oxide alone continues to crystallise, and becoming hypo-eutectoid. When the superfusion of copper is first deposited and then the eutectic, phenomena are clearly indicated in the cooling curve, which is a minimum corresponding to the superfusion, a maximum corresponding to the crystallisation of copper, followed by a step indicating the solidification of the eutectic. When solidification proceeds rapidly, crystals of copper do not appear, the normal mixture of cuprous oxide and eutectic being obtained.—A. S.

ium; Extraction of — from Natural Lead Vanadate, and the Preparation of Alloys of this Metal. Fenschmidt. Osterr. Z. Berg. u. Hüttenw. 1905, 501; Chem.-Zeit. 1905, 29, Rep. 141.

AL lead vanadate, containing 12—14 per cent. of cuprous oxide, and about 50 per cent. of lead, is melted in contact with sodium carbonate and coke. The lead is thereby reduced to the metal, and a slag is formed containing sodium aluminate, vanadate and silicate. The slag is melted separately, and submitted to oxidation, converting all the vanadium into vanadic acid, then run into water and lixiviated several times. The solution is freed from silicic acid by evaporating to a syrup, and with sulphuric acid (66°), and passing through a press. The resulting solution of sodium sulphate and vanadic acid is evaporated to expel the excess of cuprous acid, and, after washing with water, furnishes a residue of 92—95 per cent. of the vanadic acid.

In order to prepare ferro-vanadium, this product is mixed with ferrous sulphate and sodium carbonate, and precipitate thus obtained dried and treated either in an electric furnace or with "Thermit." Copper- and vanadium may be prepared in a similar way.

—B. J. S.

le Ores; Action of Sodium Nitrate on — [and Preparation of Red Lead]. J. Matuschek. Chem.-Ztg., 1905, 29, 510—511.

author finds that on heating certain metallic sulphides—galena, stibnite, copper glance, copper pyrites, etc.—with sodium nitrate, a violent reaction takes place.

There is usually a production of metal from the sulphide, but always, and, in trying to repeat some of the experiments, it was found that the yields of metal obtained were greatly reduced. Potassium nitrate appears to act more effectively than sodium nitrate.

A convenient method for the preparation of minimum lead is as follows:—Some potassium chlorate is added to potassium nitrate and lead is then introduced; the mixture is heated until no more gas is evolved. The red lead so obtained is free from litharge.—C. E. F.

Metals; Reciprocal Replacement of — in Alloys. G. McPhail Smith. J. Amer. Chem. Soc., 1905, 27, 540—551.

The author has found that the metals in the following pairs are able to replace each other in a given alloy, the first-named, or more electro-positive metal, in each case, under ordinary circumstances, more readily than the second, than the second by the first: Potassium-sodium, potassium-barium, sodium-barium, zinc-copper, cadmium-copper, iron-mercury, iron-silver, mercury-silver, mercury-platinum, mercury-gold, silver-gold. The conditions favourable for the replacement of the second or more electro-negative metal, by the first, are:—(1) High osmotic pressure (i.e., high concentration) of the ions of the second metal; (2) great electrostatic pull, i.e., high solution pressure of the first metal and low osmotic counter-pressure (or low concentration) of the ions of this metal.—A. S.

Brazing of Copper and other Metals. Soc. Ac. Dissons Du Sud-Est. Fr. Pat. 349,079, Dec. 17, 1904.

AN alloy of copper and tin containing phosphorus five per cent. and tin up to six per cent. is employed as a solder or brazing agent. — J. H. C.

GERMAN PATENTS.

Soldering Paste for Cast Iron. E. Herzog, Ger. Pat. 154,519, May 6, 1902.

THE soldering paste consists of a mixture of pure iron powder, free from oxides of iron, with steel or iron powder, 80—120; paraffin oil, 1—20; borax, 30—50, and camphor, 1—4 parts. The paste, and after addition of borax and solder, he to bright redness. — A. S.

Ores, Fin., and Ores which Disintegrate on Heating; Process for the Preparation of — for Smelting, Ges. f. Chem. Ind., Ger. Pat. 156,709, Feb. 23, 1904.

ACCORDING to Ger. Pat. 113,863, ores such as bog iron, burnt pyrites, &c., in a finely-divided condition, prepared for smelting by mixing them with smelting and the necessary fluxes, and sintering the mixture, passing it continuously through an inclined, reverberatory furnace, the ore mixture being fed at the rear end of the furnace and discharged at the front, the heating flame extended through the whole length of the furnace in the opposite direction. It has been found, however, that in this process, the ore mixture is fritted too soon and frequently stops up the furnace, especially in those parts which are accessible on difficulty. According to the present patent, only part of the heating flame or gases is allowed to travel the entire length of the inclined rotating portion of the furnace, whilst the remainder, after heating the front portion, returns in the opposite direction and through an outlet near the inlet for the heating gas. It is claimed that by this method the ore mixture is sintered only when it approaches the discharge of the furnace. — A. S.

Ores of all Kinds, Burnt Pyrites and Waste Products; Process for the Briquetting of — W. Budden, Ger. Pat. 157,136, March 22, 1903.

THE ores, &c., are mixed with a double sulphate of an alkali metal and a heavy metal, such as iron, manganese, &c., either in the form of a strong solution, or if the ore contain sufficient moisture, in the solid condition. Briquettes are made from the mixture in the usual manner. If the ore contain ferrous sulphate, it is only necessary to add an alkali sulphate or bisulphate. — S.

Air Blast; Process and Apparatus for Heating the means of the Heat of the Slag. Wassily von Isenhardt, Ger. Pat. 157,446, Oct. 10, 1903.

THE air blast is heated by bringing it into contact with a shower or spray of molten slag. — A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

ulator Plates; Improved Method of Preliminary Treatment for —. H. Leitner, Woking, Surrey. Eng. Pat. 14,128, June 22, 1904.

invention relates to an improvement on Eng. Pat. of 1904 (this J., 1905, 243), in which an electrolytic formation of Planté positives consisting of a solution containing 0.5 to 2 per cent. of sodium sulphate, and parts per 1,000 of sodium chloride was claimed, according to the present patent, the salts mentioned are used by equivalent quantities of sulphuric and hydrochloric acids.—B. N.

ies; Secondary —. W. Gardiner, Chicago, Eng. Pat. 27,900, Dec. 20, 1904.

invention relates to an accumulator comprising a receptacle with separating strips of insulating material arranged in pairs on opposite sides of the vessel, the strips having grooves extending over a portion of the ends of their inner faces. The positive element consists of a perforated sheet lead, folded transversely into a series of integrally connected folds, within which is the active material, the latter being formed electrolytically. The positive element is supported in the grooves of the insulating strips, so as to be out of contact with any part of the cell. Copper wire gauze, plated with silver, in connection with the outer receptacle, and is arranged in strips, the wire gauze serving as a support for the metallic deposits from the electrolyte, these forming the negative element. The electrolyte is a solution of sulphuric acid, zinc, mercuric and potassium sulphates.—B. N.

er and Hydroxyl Derivatives of the same; [Electrolytic Process for the Manufacture of —. L. Scholvién, Braunschweig, Germany. Eng. Pat. 24,554, Nov. 12, 1904. Under Int. Conv., May 27, 1904.

using Liquids; Apparatus for —. L. Dion, New York. Assignor to the American Electro-Hermetic Co., New York. U.S. Pat. 789,146, May 9, 1905.

DEPOSIT, with an insulated interior and with conical chambers, provided with positive and negative electrodes, a liquid to be treated is delivered through an upper distributor over the electrodes. The liquid, after electrolysis, is discharged from the lower end of the chamber into a settling tank, the latter being provided with overflow connected with the lower ends of filtering chambers, which have conical ends and insulated interiors. The filtering chambers have flexible outlets at their upper ends, the outlets being connected above to the overflow discharge and below to moving filters which are actuated by stationary brushes. The deposited material is thus returned to the settling tank, where it is removed in a suitable manner. Projections extend from the outlets and rotating cams, on a shaft supported by bearings, from the filtering chambers, engage with the projections on the filters, giving a reciprocating motion to the filters.—B. N.

Chromium; Electrolytic —. H. R. Carveth and W. R. Mott. J. of Phys. Chem., 1905, 9, 231—256. Chem. Centr., 1905, 1, 1364.

In their experiments on the electrolytic separation of chromium, the authors worked with a diaphragm and with copper cathodes that were withdrawn from time to time for the determination of the separated chromium, fresh cathodes being inserted in their place. The chromium was determined by dissolving in hydrochloric acid, and measuring the hydrogen evolved; chromous chloride is formed quantitatively. With solutions of chromic chloride (containing 100 grms. of chromium per litre), the yield rose from 9.5 to 30 per cent. at 22° C., when the current density was increased from 50 to 70 ampères per sq. dm. No increase of the yield was caused by rise of temperature, but, on the contrary, the character of the deposit was affected injuriously. On passing air through the electrolyte, the yield diminished, owing to oxidation of the chromous salt, the presence of which is necessary for the deposition of metal. Neumann's statements with regard to the influence of the anode solution (this J., 1901, 816) were confirmed; this influence is due to diffusion into the cathode solution. Sulphate solutions behave similarly to chloride solutions. The presence of acid in the solution causes a decrease in the yield, but an improvement in the condition of the deposited metal.—A. S.

Tin and Zinc; Crystallisation of —, by Electrolysing their Salts. A. Saposchnikow. J. russ. phys.-chem. Ges., 1905, 37, 153—156. Chem. Centr., 1905, 1, 1365—1366.

The author obtains microscopic preparations of tin and zinc crystals in the following manner:—A glass plate is placed on two pieces of glass rod in a shallow dish with a flat bottom. Two wire electrodes (of copper and tin or zinc) are fixed to the glass plate, and the latter is covered with stannous chloride (or zinc chloride) solution. On passing an electric current from two accumulators through the wires, crystals of tin (or zinc) are deposited at the cathode, and after being washed and dried, can be permanently fixed on the glass plate by means of a balsam.—A. S.

ENGLISH PATENTS.

Metallic Deposits upon Metal; Production of — to Prevent the same from Oxidation. A. Lévy, Paris. Eng. Pat. 9836, April 29, 1904. Under Int. Conv., May 1, 1903.

Antimony, Improved Process of Electro-depositing ——. A. G. Betts, Troy, N.Y. Eng. Pat. 15,294, July 8, 1904.

A solution, containing 8 per cent. of antimony trichloride, 2 per cent. of sodium sulphate, and 4 per cent. of sulphuric acid, is electrolysed, using an insoluble anode; metallic antimony is deposited on the cathode, and hydrochloric acid is formed at the anode, the latter consisting preferably of lead rods wrapped in layers of cloth. By using impure antimony as the anode, purified antimony is deposited, and valuable impurities remain as anode residue.—B. N.

Metal Mixtures, produced as a By-Product in Electrolytic Metal Refining Operations; Improved Process of Treating the ——. A. G. Betts, Troy, N.Y. Eng. Pat. 15,298, July 8, 1904.

This invention relates to an improved process for treating anode slime, which usually contains free or combined lead, copper, arsenic, antimony, silver and gold in a finely divided condition. The slime is agitated with a hot 4 per cent. solution of ferrie sulphate containing 2 per cent. of sulphuric acid; copper, lead and silver are converted into sulphates, and arsenic, antimony and bismuth into oxides or basic sulphates. The silver is precipitated with metallic copper, the solution filtered and the residue washed thoroughly. The insoluble portion is treated with hydrofluoric acid, hydrochloric acid or cream of tartar solution to extract the antimony, and the slime then worked up by fusion or other methods. The free acid in the filtrate is neutralised with copper oxide in a suitable manner, and the reduced solution is passed first through the cathode compartments and then through the anode compartments of an electrolytic cell, using copper cathodes and carbon anodes. Copper is deposited and ferrie sulphate regenerated. The arsenious acid is removed periodically from the solution in a suitable manner, as by crystallisation, and the ferrie sulphate used over again for treating a further quantity of slime. Instead of ferrie sulphate, chromic or permanganic acids may be used, the reduced solution being afterwards re-oxidised by electrolysis or by reaction with lead peroxide. By using fluosilicic acid in combination with these, the reduction by the metals of the slime, and the re-oxidation by lead peroxide may be carried on simultaneously. The resulting solution is treated with copper to precipitate silver, then with lead to precipitate copper, arsenic, antimony, &c., and the solution finally electrolysed to regenerate lead peroxide and the free acid, which may be used for further treatment of slime.—B. N.

UNITED STATES PATENTS.

Metals; Plant for the Electrodeposition of ——. A. G. Betts, Troy, N.Y. U.S. Pat. 789,353, May 9, 1905.

This invention relates to an apparatus for depositing lead from a suitable electrolyte, and consists of a number of tanks, each tank containing sets of positive and negative unipolar electrodes in series, and with each set arranged internally in multiple.—B. N.

Copper-Nickel Alloys; Process of Electrolytically Refining ——. A. G. Betts, Troy, N.Y. U.S. Pat. 789,523, May 9, 1905.

A solution of copper and nickel sulphates is electrolysed, using an alloy of copper and nickel as the anode; copper is deposited and nickel sulphate remains in solution. The latter is then electrolysed, using an anode of spongy lead, nickel being deposited on a suitable cathode, and the lead sulphate formed is reduced to spongy lead by making it the cathode in an electrolytic cell, sulphuric acid being simultaneously formed. The acid is then electrolysed, using an anode of copper and a cathode of lead peroxide; copper sulphate is reformed and is returned to the bath in which copper is deposited.—B. N.

Galvanising, Tinning, or otherwise Plating Wire or other Metallic Bodies; Process of ——. G. A. Goodson, Providence. Assignor to Goodson Electric Galvanising Co., Minneapolis. U.S. Pat. 789,690, May 9, 1905.

Gutta-percha from German New Guinea. A. Tschirch and O. Müller. Arch. Pharm., 1905, 243, 114—132. See also this J., 1903, 1250).

In describing the constituents of a gutta-percha from German New Guinea, the authors adopt a new terminology. The terms gutta, alban, fluavil, albanan, are retained, but are used to designate groups of substances, of which the fluavils are soluble in boiling alcohol, the fluavils in cold alcohol, and albanans neither in boiling or cold alcohol. Individual compounds in the different groups are designated by the letters α , β , γ , &c., compounds, the α -compound being the one with the highest melting point, and prefixes are used to indicate the origin of the substances, for example, guinealban from a Guinea gutta-percha, and sumatralban from a Sumatra gutta-percha. The results of a recent investigation are given under the following headings:—Solubility of the gutta-percha in different

media; fluavils: α -guinealfluavil, β -guinealfluavil, and γ -guinealfluavil; albanan: α -guinealban ("needle alban"), β -guinealban ("crystal alban"), γ -guinealban ("sphaerite alban"); guinealfluavil; guinealfluavil; phytosterol reactions.—A. S.

Gutta-percha, Sumatra; Albans and Fluavil from —. A. Tschirch and O. Müller. Arch. Pharm., 1905, 243, 133—149.

The results of the investigation are described under the following headings:— α -sumatralban ("crystal alban"), β -sumatralban ("sphaerite alban"), γ -sumatralban ("isosphaeerite alban"), phytosterol reactions; comparison of the constituents of New Guinea and Sumatra gutta-perchas.—A. S.

Rubber, Mikindani, from German East Africa; Albans from —. A. Tschirch and O. Müller. Arch. Pharm., 1905, 243, 141—146.

The authors describe the preparation and properties of the resin and alban (α - and β -danialban) of Mikindani rubber (so-called "Mozambique balls"), and also a table showing the composition of caoutchouc resins which have been previously analysed, and of compounds obtained from such resins.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Catguts; Sterilisation of — by means of Benzene. Beslier. J. Pharm. Chim., 1905, 21, 497—499.

The catguts, wound on glass bobbins, are placed in a copper bomb containing pure benzene, and closed by a screw stopper. The bomb is set in an autoclave, and the benzene is boiled for about 20 minutes. By this preliminary process, the catguts are partially dehydrated and deprived of grease. The bobbins are next put into open vessels and these in another bomb containing benzene, which is closed, and its temperature gradually raised until the internal pressure attains two atmospheres, when the temperature is allowed to fall slowly. The operation takes about $1\frac{1}{4}$ to $1\frac{1}{2}$ hours. After first siphoning off and finally evaporating off all the benzene, 70 per cent. alcohol is introduced into the bomb, the open glass vessels containing the catguts (and now filled with alcohol) are withdrawn, and closed for preservation.—E. S.

Leather, Enamel; and Process of Making same. W. W. Adams, jun., Philadelphia, and H. C. McKay, Essington, Pa., Assignors to American Patent Kid Co., New Jersey. U.S. Pat. 789,249, May 9, 1905.

UNSTUFFED tanned skins are prepared for enamelling with

the usual surface enamels, by smoothing the unbuffed grain side of the skin, extracting the grease, and then applying a solution of pyroxylin and boiled lard oil in a suitable solvent, whereby a thin, transparent and flexible coating is formed upon and adheres to the skin. The enamel is applied on the top of this coating.—A. S.

Adhesive (Carson) and Method of Making same.—G. A. Theib and L. Preaubert, Nantes, France. U.S. Pat. 788,857, May 2, 1905.

See Fr. Pat. 331,805 of 1903, this J., 1903, 1200.—T. E. B.

FRENCH PATENT.

Glue and Glueing Process and Apparatus for Fatcuring — from Bone. H. Hilbert and The Bayerische Act.-Ges. für chem. und landwirthschaftl.-chem. Fabrikate. Fr. Pat. 349,045, Dec. 16, 1904.

Soluble nitrogenous bases and their salts, which impart an unpleasant odour to the glue, are eliminated by means of a preliminary washing of the bone meal with water. The apparatus claimed for the purpose consists of a horizontal drum rotating round a hollow shaft which carries a suitable agitating device. The drum is provided with manholes, &c., whilst steam can be introduced through perforations in the shaft. There is also a perforated false bottom on which the meal rests after the washing and extraction of the glue, and the washings and colloidal solutions are driven through the deposit by means of compressed air or other agent.—C. A. M.

XV. — MANURES, &c.

Calcium Nitrate in Agriculture. E. S. Bellenoux. Comptes rend., 1905, 140, 1190.

EXPERIMENTS carried on for several years, in which potato and sugar-beet were cultivated in neighbouring portions of land, and manured with calcium nitrate and sodium nitrate, showed that for both crops the calcium salt was markedly superior. Calcium nitrate is readily prepared by the reaction of solutions of calcium chloride and sodium nitrate, sodium chloride being deposited, and calcium nitrate remaining dissolved.—J. T. D.

Vinasse; Manurial Value of —, compared with Ammonium Sulphate and 40 per cent. Potassium Salt. Lilienthal. Illust. Landw. Zeit., 1904, 34; Z. Spiritusind., 1905, 28, 201.

THE vinasse which contained 3.5 per cent. of nitrogen and 13 per cent. of potash, was employed as a dressing for potatoes (before planting), in conjunction with superphosphate and in comparison with ammonium sulphate and 40 per cent. potassium salt, the proportions being so arranged that each plot received the same quantity of nitrogen, potash and phosphoric acid. The crop was about 2 cwt. per acre less, but the percentage of starch (15.6) in the tubers was 0.9 per cent. higher than with the ammonia and potash fertiliser. In another series, both fertilisers were supplemented with sodium nitrate in one case and with ammonium sulphate in the other, the results working out on the same lines as before, with a small margin in favour of the last-named mixture. The residual effect of the vinasse fertiliser is slightly better (on a succeeding rye crop) than the potash-ammonia mixture, and the superiority of ammonium sulphate over sodium nitrate as an adjunct to the former fertiliser is also manifested here.—C. S.

UNITED STATES PATENT.

Calcium Phosphate; Process of Making Dibasic —, R. Arens, Marxloh, Germany. U.S. Pat. 789,647, May 9, 1905.

To a solution of monobasic calcium phosphate, heated to about 90° C., a solution is added of calcium bisulphite also containing monobasic calcium phosphate, and the heating is continued, to obtain dibasic calcium phosphate with recovery of the sulphurous acid.—E. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Sugar Factory; Clarification in the —. R. E. B. Louisiana Planter, 1905, 34, 240—243.

THE methods of removing the impurities thrown precipitated during clarification are as follows:—settling the juice, either before or after removing the "blanket," in the clarifiers or in settling tanks. In cases the settled, or partially settled, juice is brought to brushing pans and boiled and brushed as an adjunct removing the impurities, and then settled in settling tanks. Second, filtering the juice, several devices being utilised a view to economise space and time. Settling thoroughly has been found by repeated tests to remove practically all the precipitated impurities, whilst filtering, some always remain suspended in the juice. The average filtering surface per ton of cane is 1.69 sq. ft. The average press cake is 35 lb. per ton of cane, with an average of 5.7 per cent. of sucrose loss. This indicates a loss of 2 lb. of sugar per ton of cane washing, it is not impracticable to reduce this loss to 0.74 lb. The washings may be used as saturation thus bringing about the same dilution and extraction economising in evaporation.—L. J. DE W.

Cane Sugar Products; Fermentation in —. A. Browne, jun. Louisiana Planter, 1905, 34, 238—240.

THE majority of micro-organisms are unable to work injury within the body of sound canes because the plant generates enzymes, some of which, on exposure to air, produce toxic products which prevent the invasion of bacteria through parts that are bruised or injured. When the cane is killed, however, as by being frozen, this is lost; the formation of toxic products does not prevent bacteria invade the body of the cane through cracks and "dead eyes" and within a few days, especially if the weather becomes warm, the cane will have perished to such an extent as to be useless for manufacturing. An analysis of the juice from a batch of canes before and after a frost, shows a great decrease in the sucrose and increase in dextrose, free acid, gums, and the product of mannitol, &c. While fermentation within the body of the cane is exceptional, it may take place at any time upon its surface, as when the canes are infected by the "pou-put" insect. This insect feeds upon the inner surface of the leaf-sheath, causing the reddish discoloration from the enzymes. The juice, which exudes from the wounded surface, runs upon the stalk, and, undergoing fermentation, leaves a deposit of gummy matter. This gum, which has a sweetish taste and a peculiar characteristic odour, was found to consist mostly of dextran with a considerable amount of dextrose, and a little mannitol and trace of sucrose.

If sugars intended for storage or long shipment are thoroughly dried, the losses from deterioration would be greatly minimised.—L. J. DE W.

Molasses from Louisiana Sugar Houses; Composition of —. C. A. Browne, jun. Louisiana Planter, 1905, 34, 237—238.

INVESTIGATIONS were conducted upon the chemical nature of various molasses to ascertain to what extent the composition is affected by the difference in the process of manufacture. The lowest purity found in third molasses was about 35; in cases where reports are made of purities of 20 or under, these may result from fermentation or inversion of the sucrose, but are usually the consequence of faulty methods of calculation, the degree Brix of dry molasses being taken instead of the total solids, and the direct polarisation instead of the determination of sucrose by the Clerget method. Open-kettle molasses was less exhausted than other grades, having naturally more sucrose and less impurities such as gums, ash, amides, &c. Diffusion molasses has a larger percentage of impurities owing to a greater extraction of these ingredients from the bagasse. The effect of liming is very pronounced, molasses which has had the heaviest treatment being highest in gums and cement acids. A large part of the compounds designated as gums and acids do not come from the cane, but

sult of the action of lime upon the invert sugar of the
Clarification with phosphoric acid has a marked
ness. Part of the lime is removed as insoluble phos-
phate, and the percentage of phosphoric acid is usually
used. The phosphoric acid naturally occurring in
Guiana molasses does not exceed 0.25 per cent. In
cases dilute phosphoric acid is used for washing
sugar in the centrifugals and this has been known
to improve the appearance of high-grade molasses by
ring it turbid through precipitation of calcium
phosphate. When molasses is left over in the hot room,
there is a gradual formation during the summer time
of a thick coating of yellowish-white scum. An analysis
of dried scum gave the following percentage com-
position:—Moisture 10.00, chitin 11.30, protein 31.62,
fat 17.50, ash 5.58, carbohydrates, &c., 14.00. An
analysis of the fat showed it to have almost the same com-
position and characteristics as butter fat, and to yield
over large quantities of butyric acid upon saponifica-
tion. These scums are of fungoid origin, and are pro-
duced from the ingredients of the molasses, the latter,
however, undergoing marked deterioration, as
shown by the following analysis from the surface of
infected tank:—Brix 69.66, sucrose 1.72, co-efficient
of purity 2.47 per cent. There are thus other factors than
moisture which can exhaust molasses of sucrose
and reduce low purities.—L. J. DE W.

Juices; Apparatus for Continuous Sulphuration
of ——. A. Maguin, Charmes, France. U.S. Pat.
7372, May 9, 1905.

Sugar juice contained in a reservoir is withdrawn by
a pump and forced through the nozzle of an injector, the
jet of which communicates with a vessel in which a
jet of sulphur dioxide is maintained. The juice thus
comes in intimate contact with the gas which it draws
in through the injector and is discharged therefrom into
a juice reservoir.—J. F. B.

FRENCH PATENT.

and Farina; Sieve for Extracting — from
Ground or Rasped Materials. W. H. Uhlend. Fr.
Pat. 348,992. Dec. 14, 1904. Under Int. Conv.,
Paris, 1889.

ground or rasped material, suspended in water, is

fed by means of a hopper on to a series of sieves
arranged in steps. The whole system is supported on
a pedestal by which a circular oscillating motion is
communicated to the sieves, whilst sprays of water are directed
on each sieve. In this manner the material is
thoroughly stirred about and washed, the fine particles
collected below the sieves, whilst the coarser particles
flow away from the end. J. F. B.

GERMAN PATENTS.

Sugar; Process and Device for Separating — from
Centrifugal Apparatus. A. Müller. Ger. Pat. 157,264,
Jan. 27, 1904.

In order to expedite the removal of the syrup adhering
to the sugar crystals, at the commencement of the "cover-
ing" process, a portion of the cold air surrounding the
centrifugal machine is sucked in by means of the super-
heated steam injected into the apparatus, so that a mist,
which is free from drops of condensed water is formed.
In the apparatus described, a water-separating chamber
is arranged above the cover of the centrifugal machine,
and is provided with a tangential inlet for the steam and
an outlet for the condensed water. The superheated
steam introduced into the water-separating chamber passes
through a tube which opens below into the drum of the
centrifugal machine, and is surrounded by a jacket
provided with openings through which air is sucked in.
As the sugar becomes heated by the steam, the tempera-
ture of the air sucked in rises, and the mist gradually
disappears, so that the "covering" agent is first a mist,
then saturated steam, and finally dry or superheated
steam. It is claimed that in this way the impure sugar
is converted in as short a time as possible, and, with the
minimum consumption of steam and loss of sugar, into
pure, dry crystals.—A. S.

Syrup; Process for the Preparation of an Edible —
from the Residual Molasses of the Strontia Process.
A. Wohl and A. Kolrepp. Ger. Pats. 156,986, Aug.
13, 1903; and 156,987, Nov. 14, 1903.

The residual molasses of the strontia process is treated
with lead saccharate, with or without addition of an acid.
It is found that in the case of the molasses referred to,
the lead saccharate precipitates all non-sugar substances,
including those to which the bad taste and odour are
due, whereas, with all other kinds of molasses, only
colouring matters and the like are removed by lead
saccharate.

In Pat. 156,987, claim is made for the use of other
insoluble basic lead compounds, such as lead hydroxide
and basic lead nitrate, in addition to lead saccharate.

—A. S.

Starch; Centrifugal Apparatus on a Horizontal Axis,
intended specially for the Manufacture of ——. F.
Kachl. Ger. Pat. 155,562, Aug. 1, 1903.

The apparatus consists of two conical portions, *a*, *b*, joined together at an obtuse angle. The drum thus formed is mounted on the shaft *d* by means of the two hollow hubs *e*, *c*, of different diameters, one of which (*b*) serves for the introduction of the material to be treated, and the other (*c*) surrounded by the chamber, *f*, as an outlet for the separated water. The plates *g* closing the outlet openings for the separated starch can be displaced during the rotation of the drum by means of a fork *m* mounted on the screw *q*, within the chamber *k*.—A. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Grain. The Effect of Moist Conditions on — J. F. Hoffmann. *Wech. f. Brau.*, 1905, 22, 245–252.

GRAIN may become moist during storage either by absorption of moisture from the air or by the production of moisture as the result of internal chemical changes. The drier the initial condition of the grain, the more intense will be its capacity for absorbing moisture from the air, and the greater will be the amount of heat developed in the process. This heat stimulates respiration, which gives rise to the production of more moisture and heat, with the result that grain ripened and harvested in dry weather may eventually arrive at a worse condition than grain harvested with more moisture. This effect has been experienced with the barleys of the 1904 crop, as a result of the exceptionally dry summer. Moisture may also be absorbed by grain by a process of precipitation as dew, especially in the spring. The grain in store becomes cooled down to a very low temperature during the winter, but owing to its low conductivity it takes a long time to regain the normal temperature, consequently, when the warm moist air of the spring comes in contact with the grain, there is a copious deposit of dew, the absorption of which causes heat, sweating and mould. The chemical processes which cause changes in the moisture and temperature of grain are those involved by the condensation, hydrolysis or respiration of the carbohydrates and albuminoids. The processes which predominate are the respiration of sugars with production of water and heat, and the condensation of cane sugar to starch with production of water and a slight absorption of heat. The water produced is absorbed by the grain with the further production of heat, and the respiration is thereby stimulated. In a dry season, the chemical condensations which represent the condition of ripeness are retarded in the field, and only take place under the influence of air and moisture during the process of after-ripening in the store. —J. F. B.

Fermentation Tuns; Internal Coating of — C. F. Gabel. *Wech. f. Brau.*, 1905, 22, 252–253.

THE author has found that a mixture of brewers' pitch and paraffin constitutes the best and cheapest coating for the interior of fermentation tuns (see this J., 1904, 198–199). The mixture forms a dark-coloured coating on which any residues of yeast are plainly visible when cleaning out, and which penetrates the pores and fills up the cracks in a more satisfactory and permanent manner than any other material. The mixture should be made in the brewery itself, using only the purest materials, and it should be applied by means of the pitch-spraying machine. —J. F. B.

Beer, Analysis by the aid of the Refractometer. — G. Barth. *Z. ges. Brauw.*, 1905, 28, 303–306.

THE determination of the specific gravity and of the refractive index by means of a Zeiss immersion refractometer, affords a very simple and rapid means for the calculation of the percentages of alcohol and extract in beer (see this J., 1905, 553). The author sets forth the experimental data on which the calculations are based, and deduces the values of the constants employed in solving the equations.

Let *x* be the percentage of alcohol, and *y* the percentage of extract or degrees Balling of the beer, and *r* = the difference between the refractive index of the beer and that of water (both at 17.5°C.) determined to six decimal places and multiplied by 100,000, whilst *s* = the difference

between the sp. gr. of the beer and that of water (both at 17.5°C.) determined to five decimal places and multiplied by 100,000; then

$$x = 0.007598r - 0.002923s,$$

$$y = 0.003366r + 0.001303s.$$

The values so found for the alcohol and the extract in the case of beers of ordinary composition agree very well with those determined by the distillation method, and serve as an accurate basis for the calculation of the original gravity of the wort. —J. F. B.

Brandy; Conditions affecting the Ester [Ester] of — P. Schidrowitz and F. Kaye. *Analyst*, 1905, 30, 149–152.

THE authors have observed a considerable diminution of the ester value of brandy when the spirit was diluted with ordinary water (New River Co.) and allowed to stand for a few days, whereas, dilution with distilled water had little, if any, effect upon the ester value.

The use of ordinary water also reduces the acid value of the spirit, and has more influence on its colour than distilled water.

The authors have also found that when different brandies are mixed together for blending, the values for total acid, volatile acid and esters in the blended product generally differ very considerably from the mean values calculated from the composition of the original brandies employed. These differences are sometimes above and sometimes below the calculated mean values, and may appear to become greater with the lapse of time. The authors remarked that the alkalinity of glass bottles used for spirits may have a considerable influence on the composition of the latter. —J. F. B.

Starches; Saccharification of Artificial — E. J. Comptes rend., 1905, 140, 1259–1261.

THE author has studied the saccharification of "artificial" starches (see this J., 1905, 285 and 507) by malt extract at various temperatures, in comparison with that of ordinary starch paste. After an action lasting for four hours the principal product was maltose, no dextrin being produced. At a temperature of 56°C., the proportion of apparent maltose produced from the "artificial" starches, as against 82.3 per cent. (average) in the ordinary starch pastes. On subjecting the saccharified solutions to a process of fractionation, the extracts from the "artificial" starches yielded 54.3 per cent. of crystalline maltose, whilst those from the ordinary starch yielded only 30.4 per cent. The dextrins produced from the "artificial" starches were "almost completely soluble in alcohol."

At a temperature of 67°C., the proportions of maltose formed were 55.1 per cent. from the "artificial" starches and 15.0 per cent. from the ordinary starch. Malt extract, which had been heated to 80°C., had practically no action on a solution of "artificial" starch.

After the reversion of solutions of "artificial" starch, the residual soluble portion behaved, on saccharification, in exactly the same manner as the original solution. —J. F. B.

Starch Pastes; Constitution, Saccharification, and Reversion of — L. Maquenne and E. Roux. *Comptes rend.*, 1905, 140, 1393–1398.

THE "artificial" starches, prepared by the liquefaction of amylocellulose at 150°C. (this J., 1905, 285, 507 and the preceding abstract) and yielding normally 96–98 per cent. of maltose on saccharification, can be purified, by repeated reversion and refraction of the precipitated amylocellulose, to a point at which the products yield 102 per cent. of maltose when saccharified. Ordinary starch paste, when treated both by the saccharification test and colorimetrically by iodine, contains about 80 per cent. of a substance which is identical with "artificial" starch, i.e., amylocellulose.

Amylocellulose is partly soluble in boiling water and is completely soluble at 150°C.; its solutions are developed by gelatinising power. In the dissolved state it is decolourised by iodine, and is completely converted into maltose.

starch at moderate temperatures; in the undissolved it is unaffected by both these reagents. The reagent 20 per cent. of ordinary starch is composed of a gelatinous substance which receives the name of amylopectin and to which the gelatinising property of starch paste is due. Amylopectin is not coloured by iodine, yields no reducing sugar under the action of malt; it is converted into dextrins by the action of diastase which has been heated at 89° C., and the amylopectin dextrin of a normally saccharified starch paste is the product of the amylopectin. Artificial starch differs from ordinary starch only by the presence of the amylopectin.

Amylopectin can exist indifferently, between certain limits of temperature, and in presence of an excess of water, either in the solid or the liquid form; these modifications are reversible one into the other (a) by heating under pressure, (b) by cooling the concentrated solutions (reverse). Amylopectin occurs in the starch granule in the solid modification, capable of dissolving in boiling water and reacting with diastase and possibly it is held there by the amylopectin in the solid solution. Amylopectin has the property of reversing the reversion of amylopectin, both in the granule and in pastes. Conversely any influence tending to remove the amylopectin favours the precipitation of the amylopectin by reversion. The action of diastases is confined only to the amylopectin in the starch paste, hence such a diastase receives the name of amylopectinase; the saccharifying diastases on the other hand act only on the amylopectin (when in liquid form).—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A).—FOODS.

Rice Products; Composition and Feeding Value of ——. C. A. Browne, jun., Louisiana Agric. Exp. Stat., 1904, Bull., No. 77, 430—458.

THE rice is separated by various milling processes into different products, which are used as foodstuffs for animals. In the first place the hulls are removed by passing the grain through milling stones, screens and winnowing machines. The kernels are then decorticated, and the outer cuticle and much of the gluten layer of the grain, together with the germ, constituting the rice-bran or meal, are removed. The final process consists in polishing the grains. For this purpose, the latter are placed in rotating cylinders of wood and wire gauze, the surface of which is covered with soft, tanned hide. In the polishing process a film of gluten and starch cells is removed, and the fine flour thus obtained is called rice polish. The polished grains are then screened into various grades or sizes. In the following table are given the analyses of these products:—

	Water.	Fat.	Ash.	Proteids.	Crude Fibre.	Carbo-hydrates.	Starch.	Pentosans.
raw	10.84	0.59	14.04	5.31	32.91	33.31	—	15.84
hulls	8.97	0.49	13.29	3.50	41.89	27.36	—	17.24
meal (pure bran) I.	8.57	14.30	3.79	13.41	9.51	46.48	18.50	—
bran (16 per cent. hulls, 1 per cent. grits) II.	9.84	9.01	11.55	9.33	14.76	44.26	25.42	8.05
bran III.	10.01	9.03	8.97	9.26	11.00	52.63	—	—
polish (22 per cent. grits)	11.53	5.22	3.46	11.06	3.76	63.97	54.82	3.40
polish	10.70	6.95	2.95	8.53	1.00	60.14	—	—
rice	—	—	—	9.88	—	—	69.67	2.14
ed rice	—	—	—	6.56	—	—	77.55	—

rice hulls have absolutely no food-value, and are, in fact, injurious to cattle, as they are tough and fibrous. Under the microscope are seen to consist on the outer surface of groups of parallel rows of jagged, comb-shaped cells. Judging from the results of analyses, rice meal should contain at least 12 per cent. of proteids and 10 per cent. of fat, but not more than 10 per cent. of crude

fibre and 9 per cent. of ash. The presence of grits or broken grains of rice has been mentioned above. Although these have a high food-value, they are liable to pass through the animal undigested, and so are wasted. Rice meal, more properly called bran, is the most nutritious of the rice foods. The rice polish contains more starch than the bran, but less proteid and fat, and besides being used as a cattle-

food is sometimes employed as stuffing material for sausages.

Rice foods frequently become rancid and unpalatable owing to the decomposition of the rice oil by the enzyme, *lipase*. In some cases the oil was found to consist of nearly 90 per cent. of free fatty acids, amounting to 12 per cent. of free acid in the foods themselves. By subjecting the meals to a temperature of 200° F., the enzyme is destroyed, and subsequent production of rancidity takes place only very slowly, if at all. Another method of preventing rancidity consists in removing a portion of the oil. This also increases the food value of the meal, and the extracted oil has, itself, a considerable commercial value. Rice foods containing the natural amount of oil have a laxative effect on animals, and this would be avoided by reducing the quantity of oil to 2 or 3 per cent.—W. P. S.

Molasses Cattle Foods. C. A. Browne, jun. Louisiana Planter. 1905. 34. 236-237.

The commercial mixtures of blood and molasses, many combinations of which are prepared in European countries, offer a supply of very digestible protein, but sometimes undergo rapid decomposition in warm climates. Molasses has an antiseptic action when mixed with blood, and the activity of the bacteria which cause putrefaction is largely suspended, provided that the feed is properly dried, and that the amount of blood used is not excessive. One of the very best absorptive agents for molasses is bagasse; "molaseuit" consists of about 20 per cent. of the pithy part of bagasse and 80 per cent. of molasses. Louisiana manufacturers could greatly improve upon molaseuit, which is deficient in protein, by the addition of cotton-seed meal.

The following table gives the composition of various molasses feeding-stuffs:—

	Blood, Cereal, Molasses.	Corn, Oats, Cotton- Seed Meal, Molasses.	Corn, Oats, &c., Molasses.	Extracted Rice Bran, Molasses.	Molaseuit: Blood, Molasses.
Moisture	15.38	11.90	12.23	8.40	13.98
Fat	1.11	3.15	2.30	0.83	0.90
Ash	9.52	6.27	7.79	9.70	5.11
Fibre	12.98	14.30	12.78	13.00	5.64
Protein	16.13	12.75	6.41	14.00	1.94
Sugars	15.01	21.65	19.43	5.50	55.94
Other carbohydrates, &c.	29.87	29.98	39.06	48.57	16.49

Fruit Juices: Preparation of Non-Alcoholic —. H. Stern, Berlin. Eng. Pat. 2166, Feb. 3, 1905.

The freshly pressed juice is mixed with a suitable quantity of milk of lime in order to destroy the gummy and albuminous matters; the liquid is then saturated with carbon dioxide and filtered.—J. F. B.

FRENCH PATENT.

Flour: Process and Apparatus for Bleaching. P. A. Leperche, V. A. Salvadori and V. Denis. Pat. 319,198, Dec. 17, 1904.

The flour is fed into a closed chest and is distributed by grooved rollers so that it falls in the form of a fan down the sides of the chest. It is exposed during its fall to the action of the rays of a number of electric lamps situated in a closed chamber with glass walls, occupying the centre of the chest. The flour is withdrawn from the bottom and returned to the inlet at the top of the chest by means of a pneumatic elevator; another fan introduces air to the flour circulating through the chest in order to assist the bleaching.—J. F. B.

(B.)—SANITATION; WATER PURIFICATION.

Water: A Case of Bacterial Deposition of Iron in —. A. Beythien. Z. Unters. Nahr. Genussm. 1905, 529—531.

The water in question was delivered through iron pipes to a small town in Saxony. As it came from the pipes the water was found to contain no iron, but a considerable quantity of free carbon dioxide in solution. After passing through 2 kiloms. of main the water coming from taps, hydrants, &c., showed a large amount of ferruginous suspended matter, which was found to consist of organic matter and iron oxide. Under the microscope the deposit was seen to be composed of a mass of threads similar to *Crenothrix*, incrusting with iron oxide, and in all probability *Gallionella ferruginea*. The contamination of the water was, therefore, due to the presence of this vegetation, the presence of the free carbon dioxide also being an important factor.—W. P. S.

Nitric Acid in Water: Determination of — [by means of "Nitron"]. M. Busch. XXIII, page 638.

ENGLISH PATENT.

Filtering Materials (Sand): Apparatus for Cleaning —. F. W. Dobson, Tamworth. Eng. Pat. 10,701, March 10, 1904.

The apparatus is designed for the removal of sewer or other material from sand, so that the latter may be used over again. It consists of a large cylindrical vessel capable of holding a few tons of sand, and is mounted horizontally on bearings so that it can be rotated. The space inside is filled into the vessel through one or more man-holes. The vessel is then set rotating, and a stream of water is run through it, entering by a pipe passing through the bearing at one end, and leaving at the other by another. When the water leaving the vessel becomes clear the rotating motion is stopped, leaving the man-holes open. The water remaining in the vessel is run off by means of a small pipe, after which the vessel is given a half-rotation to bring the man-holes to the under side, and the sand then allowed to fall into sacks and back to the filter-bed.—W. P. S.

(C.)—DISINFECTANTS.

Mildew on Vines: Comparison between Normal Acetic Acid and Alkaline Copper Washes, as Preventives.

— E. Chuard and E. Porchet. *Comptes rend.*, 1905, 140, 1354—1356.

cupric acetate in 0.5 to 1.5 per cent. solution, used as a wash to the leaves and stems of vines, is partly converted into basic acetate, and adheres strongly to the plant. Not only laboratory experiments, in which the plant is treated with different washes being syringed with it after the lapse of certain intervals of time after application, but also actual exposure for a season on vines, have shown that the amount of copper compound adherent to the plant is greater with cupric acetate than with the washes made with copper salts and soda. These latter are, moreover, more difficult to prepare and to apply than is the solution of the acetate. —J. T. D.

UNITED STATES PATENT.

Process and Method of Dehydrating Moist Materials. J. Smith, Elizabeth, N.J., Assignor to American Chemical Co., New York. U.S. Pat. 786,176, May 9, 1905.

is made for the process of dehydrating a pasty material in water and a material insoluble therein, by mixing with the paste, in quantity sufficient to dehydrate the material, an anhydrous salt capable of uniting with water, and towards the insoluble material. During the mixing, the temperature is maintained at a temperature above the melting point of the hydrated salt. Claim is also made for the application of the process to the manufacture of an article, by mixing a paste of lead arsenate and water with anhydrous sodium sulphate, at a temperature above the melting point of hydrated sodium sulphate a pulverulent mixture of lead arsenate and hydrated sodium sulphate being produced.—A. S.

XIX.—PAPER, PASTEBOARD, Etc.

Pulp in Paper Making; Use of — S. C. Phillips. *J. Soc. Arts*, 1905, 53, 700—717.

chief points of this lecture fall under the headings: (I.) Wood-pulp: Countries and sources of supply, species of wood, methods of collection. (II.) Mechanical pulp: Properties and properties, plain ground pulp, steamed pulp, pulp treated with alkaline or acid solutions, grinding; Voelter's machine for grinding wood, process of manufacture, sorting and preparing the pulp for the crushing or stamping process for disintegrating cost of manufacture. (III.) Chemical pulp: Early attempts and pioneers of the industry, Ekman, Mitscherlich, Kellner; processes of manufacture, sulphite process, soda process, sulphate process, properties of wood-products, digester linings, statistics of production. (IV.) Appendices: (1) Patents. (2) Statistics of wood pulp into Great Britain.—J. F. B.

Yarn and its Uses. C. Beadle. *Paper and Pulp*, 1905, 10, 297—301.

are two processes by which paper yarn is manufactured: (1) Paper is made in separate strips on the paper-machine, the strips being collected in a bundle and twisted from these into yarn on the spinning frame; (2) the "Silvalin" process, by which the paper is made on a Fourdrinier machine and divided in the wet into a number of narrow strips, which, however, are not completely separated, but half-dried on a single reel and reeled damp in the form of a coherent web, which is subsequently placed in front of a spinning frame

and the single strips are easily separated on the drawing and spun. The latter is the more economical and simpler process. The raw material may consist of any substance capable of being made into paper; most frequently a mixture of sulphite and soda wood-pulp is employed, to which a proportion (up to 75 per cent.) of mechanical pulp may be added for the rougher yarns. Silvalin is made in counts ranging from 1,000 yards per lb. for the coarsest to 15,000 yards per lb. for the finest. Used either alone or mixed with textile yarns, it is capable of application in almost all classes of fabrics and ropes; the rougher qualities woven alone make an excellent substitute for jute sacking. It resists washing very satisfactorily. A unit plant for preparing the Silvalin paper costs about £3000, and has a capacity of 3½ tons for rough yarns or one ton for finest yarns per 24 hours. The machinery necessary for spinning the product of the above unit plant in 12 hours would contain 1300 spindles for the rough, and 2300 spindles for the fine yarns. The cost of production of Silvalin yarn, when undertaken as an addition to an existing organisation, is estimated at 1½d. per lb. for rough, 1½d. per lb. for medium, and 2½d. per lb. for the finest yarns.—J. F. B.

UNITED STATES PATENTS.

Pulp, Wood; Process for Making — G. S. Cushing, St. John, Canada. U.S. Pat. 788,633, May 2, 1905.

Wood, reduced to the condition of small chips or blocks, is subjected to the action of steam under pressure, in order to heat and expand it. While hot, it is removed to a grinding machine and ground without pressure, some water being added to it during the operation. A highly fibrous, soft pulp is, it is stated, thus obtained.—E. B.

Cornstalks, Sugar-cane, Sorghum, &c.; Manufacture of Products and Paper from — V. Drewsen, New York. U.S. Pat. 789,416, May 9, 1905.

PITHY stalks of any kind, such as maize, sugar-cane or sorghum, are chopped into pieces and boiled with a lye containing 15-30 per cent. of caustic soda, calculated on the dry weight of the material, for four to 10 hours, according to the strength of liquor, under a steam pressure of 60—100 lb., until the pith cells have been converted into soft absorbent pulp, instead of hard parchment-like pulp. The boiled pulp is run directly, without beating, upon the paper machine and converted into opaque, soft paper free from filling material.—J. F. B.

Cornstalks, Sugar-cane, Sorghum, &c.; Manufacture of Products and Paper from — V. Drewsen, New York. U.S. Pat. 789,417, May 9, 1905.

THE pulp obtained according to U.S. Pat. 789,416 (see preceding abstract) is mixed with a filling material, and is converted, without beating, into opaque, soft, "imitation coated" paper.—J. F. B.

Cornstalks, Sugar-cane, Sorghum, &c.; Manufacture of Products and Paper from — V. Drewsen, New York. U.S. Pat. 789,418, May 9, 1905.

PULP prepared according to U.S. Pat. 789,416 (see above) is converted into translucent, non-brittle writing and imitation parchment paper, by beating the boiled pulp in a beating engine, until the pith-cells have been broken up and opened, and then running the pulp on the paper-machine.—J. F. B.

Paper Pulp Straining Apparatus. F. G. Busbridge, West Malling, England. U.S. Pat. 789,792, May 16, 1904.

SEE Eng. Pat. 25,075 of 1903; this J., 1904, 677.—T. F. B.

GERMAN PATENT.

Pulp, Paper; [Electrolytic] Process for the Removal of Chlorine from and Purification of — J. F. Colby. Ger. Pat. 157,763, Dec. 28, 1902.

THE bleached paper pulp after treatment with acid, is subjected to the action of an electric current, whereby organic and inorganic impurities and particles of metal are

stated to be removed or rendered soluble, whilst the chlorine is oxidised to chloric acid, which, by the subsequent treatment with alkali, is converted into soluble chlorates. —A. S.

XX.—FINE CHEMICALS. ALKALOIDS, ESSENCES, AND EXTRACTS.

Rare Metal: Anhydrous Chlorides of Pl. — C. Matignon. *Comptes rend.*, 1905, 140, 1181—1183.

THE solution in hydrochloric acid of the oxide of the metal is evaporated to dryness on a sand-bath at 130–140° C., and the solid residue is heated in a stream of chlorine and hydrochloric acid gases charged with the vapour of sulphur dichloride. The chlorides so formed are fused, and, on cooling in the current of gases, yield a mass of minute crystals. The pure anhydrous chlorides (lanthanum, neodymium and praseodymium, samarium, yttrium) are thus prepared with great ease, and either large or small quantities can be treated. —J. T. D.

Oxalic Acid: New Synthesis of — H. Moissan. *Comptes rend.*, 1905, 140, 1209—1211.

CONTINUING the study of the reaction between dry carbon dioxide and potassium hydride (this J., 1903, 494), the author has found that when the reaction is started at a temperature of 54° C., potassium formate is the only product. Similarly, in the presence of a trace of water, when the reaction is started at the ordinary temperature, no oxalate is produced. But when the dried substances are allowed to react at initial temperatures of 80–200° C., the product consists of a mixture of formate and oxalate. The latter is formed in accordance with the equation:

the volume of hydrogen evolved being strictly equivalent to the quantity of oxalate produced. —J. F. B.

Acids: Electrolytic Reduction of Aromatic Carboxylic — to the corresponding Alcohols. C. Mettler. *Ber.*, 1905, 38, 1745—1753.

THE author has previously (this J., 1904, 1006) described the electrolytic reduction of aromatic esters. He now finds that under suitable conditions, the free aromatic acids can also be reduced electrolytically to the corresponding alcohols. One of the advantages of the electrolytic method is that the products can be more easily obtained in a pure condition than by the usual methods of preparation. Descriptions are given of the preparation of benzyl alcohol from benzoic acid, *m*-bromobenzyl alcohol from *m*-bromobenzoic acid, *m*, *o*, and *p*-chlorobenzyl alcohol from *m*, *o*, and *p*-chlorobenzoic acid, *o*-amino-benzyl alcohol from anthranilic acid and from *o*-nitrobenzoic acid, *m*-aminobenzyl alcohol from *m*-nitrobenzoic acid, *m*-hydroxybenzyl alcohol from *m*-hydroxybenzoic acid, benzyl-phenyl ether from phenyl benzoate, and dibenzyl ether from benzyl benzoate. Yields of from 70 to 90 per cent. were obtained. The following is an example of the process adopted:—The electrolysis was carried out in a glass beaker containing a porous cell, a lead anode and a sheet lead cathode having a surface of 100 sq. cm. A mixture of 30 grms. of concentrated sulphuric acid, 70 grms. of alcohol and 20 grms. of benzoic acid was placed in the cathode compartment and 30 per cent. sulphuric acid in the anode chamber. The temperature was maintained at 20–30° C. by water-cooling, and a current-strength of 10 amperes was used. During the electrolysis a further quantity of 20 grms. of benzoic acid was added. When benzoic acid could no longer be detected in the electrolyte, which happened after about 80 ampère-hours, the current was cut off, the benzyl alcohol separated from the electrolyte by diluting with water, and also by extraction with ether, dried by means of ignited sodium sulphate, and distilled. —A. S.

Alcohols: Reaction of Metal-Ammoniums on — [Alcoholate]. E. Chablay. *Comptes rend.*, 1905, 140, 1343—1344.

THE alkali-metal and the alcohol are separately dissolved in liquid ammonia, and the two solutions are then mixed.

In the case of the primary alcohols the reaction is rapid, and the cessation of decolorisation of the ammonium, as it is added to the alcohol solution, affords indication of the completion of the reaction. In the case of secondary and tertiary alcohols, it is much slower, and an excess of the alcohol solution must be added to the ammonium. —J. T. D.

Cuminoïn and Cumindl: Note on the Preparation of — H. Biltz and C. Stelbaum. *Annalen*, 1905, 339, 204—206.

THE authors find that good yields of cuminoïn obtained from ordinary cuminaldehyde, if this is purified. The cuminaldehyde is precipitated with potassium bisulphite, and after 24 hours the crystalline mass is washed with bisulphite solution, alcohol and water. The product is decomposed with sodium carbonate, distilled, and the oil fractionated in a vacuum. An alcoholic solution of this aldehyde is boiled in an apparatus with potassium cyanide, and allowed to crystallise. After recrystallising from alcohol, a 30–35 per cent. yield of pure cuminoïn is obtained, melting at 17° C. On oxidation with chromic anhydride and glacial acetic acid, there is a yield of 80–85 per cent. of pure cinnamic acid. —J. T. D.

Corydalis Alkaloids. J. Gadamer and O. Haars. *Pharm.*, 1905, 243, 147—160; 161—197.

THESE portions of the plant *Corydalis cava* which above the ground were found to contain besides the corydalis alkaloids, also bulbocapnine, $C_{19}H_{25}NO_4$, a new base, $C_{21}H_{27}NO_8$ and $C_{21}H_{25}NO_7$. With regard to the constitution of corydaline, it was found that the drcorydaline, $C_{22}H_{25}NO_5$, formed by careful oxidation of corydaline, is a quaternary base, the pseudo-*o*-acid type, which behaves as a ketone base. By reduction of drcorydaline, two isomeric inactive corydalin formed, the one melting at 135° C. being of the *o*-acid type, and the other melting at 158° C. being an *o*-mesotartaric acid. The results of oxidation experiments exactly confirmed those of Dobbie and (this J., 1902, 137), and the constitution of corydalin as indicated by those chemists.

may be regarded as proved except with regard to the position of the methoxyl groups in the first carbon (I.). (See also this J., 1902, 423, 496). —A. S.

Papaverinium Bases. III. H. Decker and O. F. b. *Ber.*, 1905, 38, 1739—1741.

DIMETHOXY-*N*-METHYL-*iso*-QUINOLONE and *N*-methyl-dimethoxy-*iso*-quinolone prepared from dimethoxy-quinoline proved to be identical with the corresponding compounds from *iso*-papaverine bases. (See this J., 1904, 336, 1160). —A. S.

Birch Buds: Essential Oil of — H. von Soden and F. Elze. *Ber.*, 1905, 38, 1636—1638.

THE essential oil obtained to the amount of 4.3 per cent. by distilling birch buds is generally viscous, and of a yellowish colour. The specimen examined had a d_4^{20} (15° C.) of 0.975; optical rotation, $[\alpha]_D^{20}$ = 29.5° C. with partial decomposition and resinification, acid being evolved; acid value, 2.1; ester value, 72; acetyl value, 177.8. On dilution with alcohol and cooling the oil to about 10° C., a small quantity of colourless, tasteless crystals was obtained; the pure substance melted at 50° C., and is thought to be a p-quin compound. The oil contains a large proportion (4 per cent.) of a sesquiterpene alcohol *betulol*, and of its ester (31.4 per cent.). The alcohol is easily isolated from the oil by means of phthalic anhydride, and shows the following properties:— d_4^{20} (15° C.), 0.975; $[\alpha]_D^{20}$ = 25° C. b. pt. (4 mm.), 138°—140° C.; (743 mm.), 284°—285° C. (with partial decomposition); it is soluble in three parts of

cent. alcohol, and has an odour resembling that of sandal-wood oil, and a bitter taste; it appears very similar to "amyrol" from sandal-wood oil, but differs in odour. Its composition is represented by the formula $C_{14}H_{12}O$, and it is probably a primary sesquiterpene alcohol.—T. F. B.

condensing the dinitrile of malonic acid or its alkyl esters with thiourea in presence of alkaline condensing agents, 2-thio-4,6-di-iminopyrimidines are obtained. These are converted (1) into 2-thio-4,6-dioxypyrimidines by treatment with hydrolysing agents, and the latter into corresponding barbituric acids by oxidising the thionyl to a carbonyl group, or (2) into 2-oxypyrimidines by oxidation, barbituric acids obtained from the latter by hydrolysis.—T. F. B.

UNITED STATES PATENT.

c Acid and its Salts; [Electrolytic] Process for Producing —. C. Ellis, Boston, Mass. U.S. Pat. 786,69, May 9, 1905.

lactic acid and its salts are produced electrolytically by oxidation of saccharine solutions, in the presence of substances forming comparatively insoluble compounds with lactic acid, these compounds being removed after separation from the field of oxidation.—R. L.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photography [“Bleaching-out” Process]. R. Nauss. Phot. Rundsch. 1905, 19, 85. Chem.-Zeit. 1905, 29, Rep. 144.

author has continued his research on the preparation of photographic natural colours, and finds that the best results are obtained by using the following solution:—10 g. of gelatin, 100 c.c. of water, 4 c.c. of Methylene Blue (in 500 of water), 2 cc. of Auramine (1 in 500 of water), and about 1.5 c.c. of Erythrosin (1 in 200 of water). The coloured solutions are added to the gelatin solution, the Erythrosin being added last; and the mixture is allowed to stand at 35°–40° C. for three to four hours. The addition of the Erythrosin or too high a tempera-

ture causes the separation of a fine, opaque precipitate which impairs the solution. The author also states that in transferring the colour pictures to paper, the photographic plate is coated with rubber and then with the colour mixture. When dry the picture film can be removed, and after dissolving out the rubber in benzene, can be pressed on to gelatinized paper.—T. F. B.

Cobaltamine Compounds [and other Cobalt Salts]; Process of — for Reducing the Silver Image. H. E. Schuch. Phot. J., 1905, 55, 185–190.

COBALTAMINE salts are found to constitute, in acid solutions, satisfactory, if rather slow reducing agents for decreasing the gradation of photographic negatives and positives. The most satisfactory salt was found to be Erdmann's salt, $Co_2(NH_3)_4(NO_2)_6 \cdot 2KNO_3$. The solution is prepared by adding 50 c.c. of 15 per cent. sulphuric acid to 50 c.c. of a 0.5 per cent. solution of the salt. The sulphuric acid may be replaced by other mineral acids. When reduction has proceeded to the desired degree, the plate or paper is washed, immersed in a 10 per cent. ammonia solution, and again washed. The following other cobaltamines also act satisfactorily:—Erdmann's salt in which the potassium nitrite is replaced by other metallic nitrites, ceric-, xantho-, and flavo-cobaltic chlorides, $Co_2Cl_2(NO_2)_4(NH_3)_8$, $Co_2Cl_2(NO_2)_6(NH_3)_4$, $Co_2Cl_2(NO_2)_4(NH_3)_6$. Double salts of cobalt nitrite with the alkali nitrites also have a similar reducing action on the photographic image.—T. F. B.

Pigment [Photographic] Process. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 349,129, Dec. 2, 1904. Under Int. Conv., June 11, 1904.

This process is based on the fact that neutral chromates which are insoluble in water have the power of rendering pigmented gelatin, in acid solutions, insoluble in water. A suitable support, e.g., paper coated with gelatin, is impregnated with a solution of a ferric salt which can be reduced by light (e.g., ferric citrate), and with a metallic salt which gives a precipitate with neutral chromates, but none with bichromates (e.g., copper or nickel sulphate, or mercuric chloride). On exposure to light, the ferric salt is reduced, and the support is immersed in a solution of a bichromate; at the portions of the paper which contain ferrous salt, reduction of the bichromate to chromate at once takes place, with simultaneous precipitation of the metallic chromate on the paper. The support is then washed, and pressed against a pigmented gelatin paper, in a bath of very dilute acid, when the gelatin in contact with the metallic chromate is rendered insoluble; after allowing the papers to remain in contact for several (three to six) hours, the print is developed in hot water in the usual manner.—T. F. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

Nitric and Sulphuric Acids; Behaviour of Mixtures of —. A. Sapozhnikow. Z. physik. Chem., 1905, 51, 609–626. (See this J., 1904, 865, 935; 1905, 87).

Vapour Pressure of Mixtures of Nitric Acid of sp. gr. 1.48 and Concentrated Sulphuric Acid. The acids used were pure 100 per cent. sulphuric acid monohydrate (H_2SO_4) and nitric acid of sp. gr. 1.467 at

15° 15' C., and containing 0.402 per cent. of higher oxides of nitrogen, so that it had the composition: nitric acid, 82.8; water, 17.2 per cent. The results obtained are shown in the following table:—

Percentage by Weight		Composition, per cent. by Weight.			Vapour Pressure.	Per cent of Nitr in Vap	
No	Nitric Acid of sp. gr. 1.48	Sulphuric Acid	Nitric Acid.	Sulphuric Acid.	Water.		Mm. of Mercury.
	100.0	—	85.2	0.0	14.8	16.64	22.6
1	97.27	2.73	82.87	2.73	14.4	19.56	22.4
2	94.86	5.14	81.0	5.14	13.86	21.59	22.1
3	90.0	10.0	76.67	10.0	13.33	26.8	22.0
4	76.68	23.32	67.87	20.32	11.81	31.30	22.5
5	68.81	31.19	59.48	30.19	10.33	33.60	22.8
6	59.91	40.09	51.04	40.09	8.87	34.12	23.3
7	50.0	50.0	42.60	50.0	7.40	31.16	22.7
8	38.25	61.75	33.41	60.75	5.81	24.88	22.1
9	30.23	69.77	25.75	69.77	4.48	18.20	23.0
10	20.07	79.93	17.10	79.93	2.07	8.40	24.2
11	10.05	89.95	8.56	89.95	1.40	—	29.0
12	5.20	94.80	4.51	94.71	0.78	—	—

It will be seen that the vapour pressure of nitric acid of sp. gr. 1.48 (1694 m.m.), is nearly three times as small as that of pure nitric acid of sp. gr. 1.52 (46.2 m.m.); see this J., 1905, 876, probably owing to the nitric acid forming relatively stable hydrates with the water, 1 mol. of water combining with several molecules of acid, and thereby considerably diminishing the concentration by volume of the latter. This also affords an explanation of why nitric acid alone, even when of the highest strength (sp. gr. 1.5—1.52), is not suitable for the nitration of cellulose, giving low-nitrated products; the water formed in the first stage of the nitration combines with the nitric acid to form hydrates, and in this way reduces the number of available molecules of nitric acid. The maximum vapour pressure is attained with a mixture containing 65 per cent. of nitric acid (sp. gr. 1.48) and 35 per cent. of sulphuric acid, or almost exactly $5\text{HNO}_3 + 2\text{H}_2\text{SO}_4 + 3\text{H}_2\text{O}$.

Action of Water on Mixtures of Nitric and Sulphuric Acids. The addition of water to mixtures containing less than about 60 per cent. of sulphuric acid, causes a diminution in the vapour pressure, the effect being less as the percentage of sulphuric acid is increased. With mixtures containing more than 60 per cent. of sulphuric acid, however, addition of water causes an increase of vapour pressure. This is due to the fact that with high percentages of sulphuric acid, some of the nitric acid is dehydrated to nitric anhydride, which, on the addition of water, is again converted into nitric acid.

Use of Mixtures of Nitric and Sulphuric Acids in the Nitration of Cellulose. A satisfactory acid mixture for nitration purposes must fulfil two requirements. It must contain sufficient nitric acid to give the desired reaction-velocity and degree of nitration; and its properties must not be appreciably altered by the water separated during the nitration. Mixtures which best answer the first condition, have, however, the disadvantage, that the volume-concentration of the nitric acid is strongly diminished by addition of water. A mixture must therefore be chosen which has a vapour pressure less than the maximum, but which will bear an addition of water without notable alteration. In the case of mixtures containing a relatively high percentage of sulphuric acid, an addition of water must be made in order to prevent dehydration of the nitric acid, with formation of nitric anhydride. The composition of acid mixtures for nitrating purposes may be varied within wide limits, but the author considers that for the preparation of high-nitrated gun-cotton, the best results will, in general, be obtained with mixtures of nitric acid of sp. gr. 1.48 with from 65 to 75 per cent. of sulphuric acid. Probably the most suitable mixture is No. 9 in the table (see above) with the addition of 5 per cent. of water, giving a mixture containing: nitric acid, 24.29; sulphuric acid, 65.80; and water, 9.91 per cent.—A. S.

UNITED STATES PATENT.

Blasting Composition. M. Bielefeldt, Berlin. U.S. Pat. 789,252, May 9, 1905.

See Eng. Pat. 25,884 of 1901; this J., 1902, 1471.—T. F. B.

FRENCH PATENTS.

Nitroglycerin: Manufacture of —. A. Mikol. Fr. Pat. 349,078, Dec. 17, 1904. Under Int. Dec. 18, 1903.

The tendency of trinitroglycerin to congeal diminishes the rise in the amount of dinitroglycerin contained in the object of this patent is to obtain a product containing a large proportion of the latter. For this purpose, a product is separated as completely as possible by water, partially neutralising the acid solution (after nitrating some alkaline substance). The formation of dinitroglycerin is promoted by decreasing the proportion of sulphuric acid in the nitration mixture, and using more glycerin usually done.—C. A. M.

Caps: Charges for —. Westfälisch Anst. Sprengstoff Act.-Ges. Fr. Pat. 348,721, Dec. 9, 1904.

The following cap compositions are claimed, which are intended to form a protective coating on the gun barrel.

(1) 36 parts of fulminate of mercury, 40 parts of (or mercury) chromate, 20 parts of antimony sulphide, and four parts of powdered glass. (2) 40 parts of fulminate of mercury, 10 parts of potassium chlorate, 26 parts of lead chromate, and six parts of powdered glass. (3) 40 parts of fulminate of mercury, 16 parts of lead peroxide, 20 parts of lead chromate, and six parts of powdered glass.—L. F. G.

XXIII.—ANALYTICAL CHEMISTRY

INORGANIC QUALITATIVE.

Sodium; Detection of Salts of —. Modified from *Fremy's Reagent*. J. Bougault. J. Pharm. Chim., 1905, 21, 437–442.

The best results are stated to be obtained with a reagent prepared in the following manner. On gram. of antimony trichloride is added to a mixture of 10 c.c. of a 33.3 per cent. solution of potassium carbonate and 45 c.c. of 10-volume hydrogen peroxide and the whole gently warmed. The precipitate formed at first gradually redissolves, and there is an evolution of oxygen. After heating for 5 to 10 minutes, the solution is cooled and separated by filtration or decantation, from any small quantity of precipitate which has not redissolved. In using the reagent, the following precautions should be observed. The solution containing the sodium salt should be neutral or alkaline, free from salts of the heavy metals, and should occupy as small a volume as possible. After adding the reagent (not more than 0.1 cc.), the mixture should be heated to boil for a few moments, and then allowed to cool. It is then to detect 0.4 mgrm. of sodium chloride. In the case of potassium salts, the reagent is much less sensitive; it is recommended that in these cases, the salts be converted into acetates and then the potassium separated as far as possible, as tartrate. Lithium also can be sparingly soluble antimoniate, but this can be distinguished from the sodium salt under the microscope.—S.

ium; *New Reagent for* —. E. P. Alvarez. *Comptes rend.*, 1905, **140**, 1186—1187.

A 1 per cent. solution of *cikonojen*, or sodium amino-sulphonate, ($\text{NH}_2 : \text{OH} : \text{SO}_3\text{Na} = 1 : 2 : 6$), is a delicate reagent for potassium in neutral solutions, giving more sensitive results than is platinum chloride. The reaction requires time; the deposition of the potassium naphtholsulphonate is favoured by shaking, but in a 1 per cent. solution of potassium chloride is only visible after some hours. The precipitate is white and fine, and brilliant, the crystals appearing under the microscope as pearly orthorhombic laminae. It is almost insoluble in water, quite insoluble in alcohol. Salts of sodium or magnesium are not precipitated by the reagent, and do not interfere with the precipitation of potassium. Many of the heavy metals behave like potassium, but others are precipitated by the reagent. —J. T. D.

Monoxide and Silver Oxide; *Reaction between* — — *its application for the Detection of Carbon Monoxide in the Atmosphere*. H. Dejust. *Comptes rend.*, 1905, **140**, 1250—1252.

Carbon monoxide is passed over silver oxide in the test tube at the ordinary temperature, the latter is reduced to metallic silver with a very considerable rise of temperature: $\text{CO} + \text{Ag}_2\text{O} = \text{Ag}_2 + \text{CO}_2$. It is preferable to pass silver oxide to $40^\circ - 50^\circ \text{C}$., in order to start the reaction. In the presence of water there is also a reduction, but extremely slow. The reduction of an ammoniacal solution of silver oxide may be utilised for the detection of small quantities of carbon monoxide in air. For this purpose, the ammoniacal silver solution is allowed to drop through a funnel into a beaker at the rate of about 20 c.c. per hour, the same liquid being passed three times in succession. By comparing the colour of the reduced silver with standardised tints, an approximate measure of the proportion of carbon monoxide may be obtained, being taken that neither acetylene, sulphuretted hydrogen nor other reducing gases are present. —J. F. B.

Colloidal; *A Red Solution of* — — *obtained by means of Carbon Monoxide [Detection of Carbon Monoxide]*. J. Enau. *Monatsh. f. Chem.*, 1905, **26**, 525—530.

Gold obtained by precipitation with oxalic acid dissolved in hydrochloric acid and a few drops of hydrofluoric acid, the solution evaporated to dryness, and the residue dissolved in "conductivity water." On passing carbon monoxide through the solution, a faint red or violet coloration appeared after two to three seconds, changing after some time to purple. The solution is identical in properties with the colloidal gold prepared by Zsigmondy (this J., 1902, 192, 1250). The same may be used as a delicate test for carbon monoxide. A few drops of water saturated with carbon monoxide will give distinct coloration, and even 1 c.c. of such water has been diluted to five times its volume will give coloration with the gold chloride solution after some time. —A. S.

Presence of Ammonia in — — *as Evidence of Spoilage*. A. Trillat and Sauton. *Comptes rend.*, 1905, **140**, 1266—1268.

The authors apply the nitrogen iodide test (see this J., 1904, 548 and 549) for the detection of ammonia in milk, in the following manner: 10 c.c. of milk are treated with a 10 per cent. solution of iodine trichloride, the mixture is filtered and pure milk of lime (1 per cent.) is gradually added to the filtrate until a precipitate of nitrogen iodide, indicating the presence of ammonia, is obtained.

Milk of healthy cows obtained under proper conditions of cleanliness in a well-ventilated house, should contain no ammonia. Ammonia is produced by the action of micro-organisms in the milk, but the absence of ammonia is no proof that the milk is not contaminated. Certain species of bacteria do not form ammonia. The presence of ammonia, especially if the quantity is small, is a presumption, but not a certain proof, of pollution or watering. —J. F. B.

Rhodium; *Reaction of* —. P. Alvarez. *Comptes rend.*, 1905, **140**, 1341—1343.

To an aqueous solution of a rhodium salt, such as sodium chlororhodate, excess of sodium hydroxide is added, and through the solution is passed the gaseous mixture evolved by the reaction of hydrochloric acid on potassium chlorate. The colourless liquid becomes yellow and afterwards red; a green precipitate is then formed, which dissolves later to a deep-blue solution. The blue solution is decolorised by sulphurous acid, or by sodium peroxide or persulphate. This reaction is very sensitive, and quite distinctive of rhodium. —J. T. D.

Osmium; *New Compound [Iodo-osmious Acid] of and Reaction for* — — *[also for Detection of Iodides]*. P. Alvarez. *Comptes rend.*, 1905, **140**, 1254—1256.

The author has found that nascent hydriodic acid is a good qualitative and quantitative [colorimetric] reagent for osmium compounds and that the latter, particularly osmic acid, are conversely available as reagents for the presence of iodides even when mixed with chlorides and bromides.

The new compound, on the formation of which this test depends, is iodo-osmious acid $\text{I}_2\text{Os} \cdot 2\text{HI}$; its solutions possess a fine emerald green colour, but the free acid is somewhat unstable and very easily oxidised, the green colour changing to red on exposure to the air. The reaction is carried out by mixing 2 c.c. of a one per cent. solution of potassium iodide with 1 c.c. of syrupy phosphoric acid, and adding to the mixture a few drops of a dilute solution of the osmium compound. The green colour is developed after stirring for one or two minutes. The reaction may be expressed by the equation $\text{OsO}_4 + 10\text{HI} = \text{I}_2\text{Os} \cdot 2\text{HI} + 4\text{H}_2\text{O} + 3\text{I}_2$. Since the green compound is extracted from its aqueous solution by ether, the delicacy of the test may be very much increased by performing it in presence of ether. The salts of iodo-osmious acid are relatively stable, and permanent green solutions are produced by forming the compound in presence of a strong solution of calcium chloride. —J. F. B.

Niobium; *Qualitative Reactions of* —. P. Melikow and E. Jeltschaninow. *J. russ. phys.-chem. Ges.*, 1905, **37**, 99—103.

POTASSIUM fluoroniobate is coloured yellow by sulphuric acid in presence of small quantities of hydrogen peroxide. Also, concentrated solutions of potassium niobate are coloured yellow by concentrated sulphuric acid. The reactions are stated to be so delicate that the presence of 0.1 per cent. of niobium in tantalum preparations can be detected with certainty. —A. S.

INORGANIC QUANTITATIVE.

Potassium Permanganate Solution; *Standardisation of* — — *by means of Silver*. K. Hopfgartner. *Monatsh. f. Chem.*, 1905, **26**, 469—482.

THE method is based upon the reaction:

A weighed quantity of pure silver is dissolved in a solution of ferric-ammonium sulphate rendered acid with sulphuric acid, and the ferrous sulphate produced in quantity equivalent to the weight of silver dissolved, is titrated with the permanganate solution the strength of which is to be determined. —A. S.

Chlorates, Bromates, and Iodates; *Reduction of* —. for the Quantitative Determination of their Halogen Content. P. Jannasch and A. Jahn. *Ber.*, 1905, **38**, 1576—1589.

THE authors have investigated the action on these salts of various reducing agents: their results are as follows:—*Nitric Acid*.—The ordinary strong acid is without action on chlorates and iodates; it reduces bromates, but as free bromine is formed, the reaction is useless quantitatively. Fuming nitric acid reduces chlorates and bromates completely, but not iodates. *Hydrogen peroxide* in alkaline solution has no action; in nitric acid solution, with certain precautions, it reduces chlorates completely;

the same occurs with bromates, but is then perhaps accomplished by the nitric acid alone. There is no reaction with iodates. *Hydrazine sulphate* in alkaline solution reduces iodates and bromates completely, but not chlorates. *Formic acid* behaves towards all three like hydrazine sulphate, save that there is a tendency for free iodine to separate. *Aldehydes* (acetaldehyde and grape sugar were tried) give no reduction; though chlorates are reduced when heated under pressure with dextrose and acetic acid. *Hydroxylamine sulphate* gave the best results of any reagent tried. In acid solution the reaction is stronger than in ammoniacal solution; the former is better for chlorates and bromates, the latter for iodates. About 0.25 grm. of the salt is dissolved in 50 c.c. of water, 5 grms. of solid hydroxylamine sulphate are added, excess of nitric acid added, and the solution warmed and afterwards precipitated with silver nitrate. In the alkaline method, excess of ammonia is added before the hydroxylamine salt, instead of excess of acid after it.—J. F. D.

Ore-Sampling: Some Experiments on—A. T. French, Inst. of Min. and Met., Bulletin, No. 8, May 11, 1905, 9-11.

In the "canvas" method, a sheet of stout canvas about 6 ft. square is employed. If the ore has not been previously crushed, the canvas is laid upon the usual iron plate, and a block of iron is placed on the canvas, upon which the ore is broken with hammers. When sufficiently small the iron block is removed and the sample is mixed by rolling from end to end. Finally it is brought to the centre by taking up the four corners and shaking to detach any fine dust. The sample is then divided into four, and two opposite quarters taken as usual. The rolling and dividing are repeated as may be considered necessary. Comparative experiments with this, the "alternative shovel," and "coning and quartering" methods are also briefly described by the author. He concludes that the canvas method is more accurate than the alternate shovel method, and equal to the coning and quartering method, but much quicker.—J. H. C.

Copper: Determination of Oxygen in—S. Dickson, Analyst, 1905, 30, 145-149.

BLOUNT'S method for the determination of oxygen in copper consists in fusing the metal in a current of dry hydrogen and collecting and weighing the water produced. The author proposes a modification of this method by lowering the melting point of the copper by the admixture of about twice its weight of tin, previously fused in a current of hydrogen. By this means the determination can be carried out in an ordinary tube furnace without a blast. The apparatus consists of a hydrogen generator, a drying-tube, a tube containing platinised asbestos for elimination of oxygen, a second drying-tube, a porcelain heating tube 1½ in. external diameter, a porcelain boat for containing the copper and tin, a tube-furnace, an absorption tube and a guard tube filled with pumice and sulphuric acid. The results obtained are slightly higher than by Blount's method. The author shows that Archbutt's method of heating the copper without fusion only yields the whole of the oxygen when the metal is very finely divided.—J. F. B.

Nitric Acid in Water: Determination of—[by means of "Nitron"]—M. Busch, Z. Unters. Nahr. u. Genuss., 1905, 9, 464-468.

Detection of Nitric Acid in Water.—From 5 to 6 c.c. of the water under examination are acidulated with one drop of dilute sulphuric acid and six to eight drops of a 10 per cent. solution of "nitron" (see this J., 1905, 289, 291, 458) in 5 per cent. acetic acid are added. If a white precipitate of "nitron" nitrate forms immediately, or if the salt crystallises out in needles within one to two minutes, the water contains more than 100 mgrms. of nitric acid per litre. If, on the other hand, no separation occurs in an hour, less than 25 mgrms. of nitric acid per litre are present.

Determination of Nitric Acid in Water.—This is carried out in the manner previously described (this J., 1905, 291), but instead of the costly Neubauer crucible, a small filter-tube may be used for collecting the precipitate. The

filter-tube shown consists of a piece of glass tubing at its upper end in the form of a thistle funnel; the filtering-material consists of a layer of very fine placed on a small perforated filter-plate.—A. S.

ORGANIC QUALITATIVE.

Asphaltum: Detection of Adulterants in Natu.—E. Malenkovic, Oesterr. Chem.-Zeit., 1905, 8, 1 Chem. Centr., 1905, 1, 1283.

THE author's experiments were made with the extracted in the Soxhlet apparatus with carbon b and dried for half an hour at 105° C. One grm. of the from natural asphaltum when boiled for about 1½ with 100 c.c. of N 10 sodium hydroxide solution light brown liquid in which the coloured particles to be uniformly suspended, but not dissolve bitumen from petroleum pitches when subjected to treatment gives a colourless solution; that from pitches, a lemon-yellow solution; and that from tar pitch, a reddish-brown liquid having an erosote. On boiling 1 grm. for a quarter of an 100 c.c. of 40 per cent. formaldehyde, the bitu natural asphaltum does not colour the liquid adulterants do so. If 1 grm. of bitumen be dis far as possible in 10 c.c. of carbon bisulphide, th filtered, treated with 90 c.c. of petroleum ether, filtered, the filtrate is red in the case of natural as red to brown in the case of petroleum pitch, as in the case of coal-tar products. On adding volume of 85 per cent. (by vol.) alcohol, af shaking, the alcoholic layer remains colourless i of natural asphaltum, but is coloured yellow wit ants. It is stated that the presence of 2-5 pe petroleum pitch in natural asphaltum can be r by this test. For the detection of larger qua paraffin, ceresin, mineral wax, &c., the bitumen is with petroleum ether, the extract evaporated to one grm. of the residue dissolved in 10 c.c. of spirit, and 90 c.c. of acetone added. In the case asphaltum, the solution generally remains cl petroleum pitch it becomes turbid, whilst with pitch and paraffin, &c., a flocculent precipitate is

The author also makes use of the maximum bro in the examination of asphaltums. About 0.5 g bitumen dried for exactly half an hour at 105° C. in a Soxhlet apparatus with carbon tetrachloride a of anhydrous bromine for 25 hours or unt bromic acid is no longer evolved. The mixtur poured into a porcelain dish, the excess of br carbon tetrachloride expelled on the water-bath, t dissolved in carbon tetrachloride, the soluti in a weighing bottle, evaporated to dryne for a quarter of an hour at 105° C. and weigh percentage of bromine taken up is called the bromine value; it is 89-93 for natural asphaltu average 67 for petroleum pitches, and 173-191 fo products.—A. S.

Dyestuffs: Differentiation of Blue Sulphur—Lüttringhaus, Z. Farben- u. Textil-Ind., 05, 214-215.

As the sulphur dyestuffs of similar shades give ve reactions with the usual reagents, and also sl difference in dyeing properties, it is very di identify the different dyestuffs. The dyestuffs dimethylamino-*p*-oxydiphenylamine (Fr. Pat. 03,622) and from dimethylaminothiazone (Fr. Pat. 308 be distinguished as follows: 10 grms. of the dissolved in 75 c.c. of warm water with 10 grms. sulphide crystals, the solution is treated with 25 40 per cent. caustic soda solution, and heated for in an open vessel to 50-75° C. with constant a strong stream of air being passed through. 200 c water and 50 grms. of salt are then added, and th tate filtered off and dried in the air.

The first dyestuff (from *p*-dimethylami diphenylamine) gives a dark violet blue powd dyes unmordanted cotton a weak violet or p whereas, the original dyestuff gives a bright bl

dyestuff (from dimethylaminothiazone) gives a color which dyes unmordanted cotton in pure blue like the original dyestuff, but a little weaker; however, four to five times stronger than those given by the product from the diphenylamine dyestuffs. Some other dyestuffs showed similar differences.

—A. B. S.

Oil in Walnut Oil; Detection of — G. Halphen. Bull. Soc. Chim., 1905, 33, 571—572.

Method given by the author, which is capable of detecting in a few minutes, the presence of less than 5 per cent. of linseed oil in walnut oil, makes use of a solution prepared by adding sufficient bromine to carbon tetrachloride to increase the volume of the latter by one-fifth. 5 c.c. of the oil is dissolved in a test-tube in 10 c.c. of carbon tetrachloride (66°), and 1 c.c. of the freshly prepared bromine solution is run in from a burette. The test-tube is stoppered, and once to mix its contents, and placed in a water-bath at 25° C. If linseed oil be present, the liquid becomes turbid in less than two minutes. The reaction is not affected by the presence of poppyseed oil.—T. H. P.

Order: Quick and Simple Method of Detecting Lead in — F. Kopecky. Collegium, 1905, 36, 50.

Lead can be detected in hide powder used for tanning by moistening 0.2—0.3 gram of the powder with a solution made by adding six parts of potassium iodide to one part of zinc chloride solution (sp. gr. 1.8) and saturating the solution with iodine. After allowing the mixture to stand for 2—3 minutes, 25 c.c. of water are added, and the mixture is mass well stirred. The cellulose particles are colored a deep violet by the treatment, and can easily be separated from the particles of hide, which become colorless.

In comparison with a standard sample, it is possible to estimate the amount of cellulose present in any sample of hide powder.—M. C. L.

Use of — with Hydrochloric Acid as a Reagent. L. Rosenthaler. Z. anal. Chem., 1905, 44, 21.

Reaction of vanillin in hydrochloric acid gives characteristic color reactions with phenols, ketones and other substances. The reaction takes place on adding a few drops of a small crystal of the substance to be tested to a solution of vanillin in hydrochloric acid; the mixture is allowed to stand for 15 minutes, and the change noted; it is then heated to boiling, when a new change is usually observed. Acetone and its isomers give, as a rule, a light rose color at first, on heating, a green color is obtained. All aliphatic ketones give some color change. Benzaldehyde and its isomers give a red coloration on heating. Morphine and its isomers give a violet-red coloration. Aromatic oils, which contain certain phenols and ketones or reactions which may be classified as follows:—Green coloration on heating is given by oils containing cineol or limonene, by oil of turpentine and generally by oils which come from trees of the coniferae; the oils of the rosaceae give no reaction.

Violet coloration after heating is obtained from oils of linalool and geraniol, e.g., the oils of linaloe, bergamot, lavender, rose and palmarosa.

Blue coloration on heating is given by oils containing oils such as cedar oil.

Bluish-green coloration on heating is given by oils of turpentine, as it contains substances giving both the blue and the green colors.

Oils which do not themselves give any color reaction, such as clove, give a coloration if they have been treated with oils like oil of turpentine and copaiba. The author states that further research into the question of these colors is necessary before the method can be conducted with any degree of certainty.

—C. E. F.

Use in Dimethylaminoantipyrine [Pyramidone or Antipyrine]; Detection of — P. Bourcet. Bull. Soc. Chim., 1905, 33, 572—573.

Antipyrine is much cheaper than dimethylaminoanti-

pyrine, and has very similar general properties, so that the latter product sometimes contains one-third of its weight of antipyrine as an adulterant. The presence of as little as 2 per cent. of antipyrine can be detected as follows:—0.01 or 0.02 gram of the dimethylaminoantipyrine is dissolved in a test tube in 4 or 5 c.c. of cold water and to the solution are added two drops of 60 per cent. sulphuric acid, and either two drops of a saturated solution of sodium nitrite or a few fragments of the crystallized salt, and the mixture shaken. If the dimethylaminoantipyrine be pure, an intense, bluish-violet coloration is immediately obtained, which, especially in presence of excess of the nitrite, rapidly disappears, leaving a colorless solution. If antipyrine is present, the violet coloration disappears gradually on shaking, especially if fresh nitrite is added, its place being taken by a persistent bluish-green coloration, the intensity of which increases with the content of antipyrine. If the latter is small, the bluish-green coloration may be observed by holding the tube vertically over white paper and looking at the surface of the liquid at an angle.—T. H. P.

ORGANIC QUANTITATIVE.

Oxalic Acid; Determination of — by Permanganate in the presence of Hydrochloric Acid. C. P. Baxter and J. E. Zanetti. Amer. Chem. J., 1905, 33, 500—506.

The authors find that oxalic acid may be very accurately determined by titration with potassium permanganate solution, in the presence of hydrochloric acid if the temperature of the solution at the beginning of the titration be not lower than 70° C. The concentration of the hydrochloric acid must not be greater than 20 c.c. of dilute acid (sp. gr. 1.04) to 150 c.c. of oxalic acid solution, and the latter volume should not contain more than 0.3 gram of crystallized oxalic acid. It is also important to add the permanganate solution slowly, and constant stirring is advisable. Loss of chlorine and consequent use of too much permanganate when the titration is performed at low temperatures may be due to the formation of hypochlorous acid which is readily volatile. Further experiments are described, which show that oxalic acid does not appreciably volatilize or decompose, in dilute solution, at temperatures as high as 90° C.—W. P. S.

Hydrazones derived from p-, m-, and o-Nitrophenylhydrazine [Detection and Determination of Aldehydes, Ketones and Sugars]. W. A. Van Ekenstein and J. J. Blanksma. Rec. trav. chim. Pays-Bas, 1905, 24, 33—39; Chem. Centr., 1905, 1, 1277—1278.

p-Nitrophenylhydrazine can be used for the quantitative determination of aldehydes and ketones. For example, from 50 c.c. of a solution of 82 mgrms. of acetone in 10 per cent. alcohol, a solution of 400 mgrms. of *p*-nitrophenylhydrazine in 15 c.c. of 30 per cent. acetic acid, precipitated 81 mgrms. of acetone in the form of its hydrazone. In a similar manner, 44 mgrms. of diethylketone were obtained from 45 mgrms., 46 mgrms. of acetaldehyde from 46.4 mgrms., and 66.7 mgrms. of benzaldehyde from 66.7 mgrms. *p*-Nitrophenylhydrazine can also be used for the separation of sucrose from dextrose, levulose and mannose. The hexoses readily form hydrazones which are almost insoluble in water, whereas sucrose does not react in alcoholic solution.

m-Nitrophenylhydrazine when warmed for a few minutes with aldehydes and ketones in alcoholic solution forms characteristic hydrazones, in most cases red crystalline compounds. *o*-Nitrophenylhydrazine also readily forms hydrazones with aldehydes and ketones. The levulose derivative, m. pt. 162° C., $\alpha_D^{20} = +31$, separates from alcoholic solution more readily than the corresponding dextrose derivative, m. pt. 158° C., $\alpha_D^{20} = +27.8$; and thus a separation of the two sugars is possible.—A. S.

Betaine in Sugar Factory Products; Determination of — V. Stanek. Z. Zuckerind. in Böhmen, 1905, 29, 410—417.

In applying the author's method for the determination of betaine (see this J., 1904, 844) to the case of impure industrial products, certain modifications are necessary to ensure good results. In the case of undefecated juices the

albumins must first be precipitated either by ether-alcohol or by cupric hydroxide. The juice, syrup, massecuite or molasses at a suitable degree of concentration, is dissolved in 50 c.c. of sulphuric acid of 10 per cent. strength, saturated with salt. The solution of potassium tri-iodide is added drop by drop so long as a precipitate is formed, and then a few grains of iodine powder (precipitated) are introduced in order to facilitate the filtration. After standing for six hours the precipitate is collected in a Gooch crucible and washed five times with 5 c.c. of saturated brine. The washed precipitate is returned to the beaker with 25 c.c. of water, the liquid is heated and copper dust (precipitated by zinc) is stirred in until the colour and smell of the iodine are discharged. The liquid is boiled and sufficient cupric hydroxide (Stutzer's reagent) is added to convert the yellow precipitate into a green one. The liquid is cooled, filtered on the pump, and the precipitate is washed 10 times with 5 c.c. of cold water. The betaine passes into the filtrate and is determined by Kjeldahl's method. The following determinations indicate the average percentages of betaine found by the author in various saccharine products: sugar, 1st product, 0.69; massecuite, 1st product, 1.70; massecuite, 2nd product, 4.43; molasses, 6.70; strontia-molasses, 4.47; strontia waste lyes, 17.41; thick juice from unripe beets, 2.65.—J. F. B.

Malt: Determination of Extract in ——. C. Bleisch and P. Regensburger. *Z. ges. Brauw.*, 1905, 28, 313—316.

In the process of determining the yield of extract from malt in the laboratory, even when the prescribed "fine-rist" is mashed, a certain proportion of available extractive matter remains behind in the unsaccharified condition in the grains. The quantity of this residual extractive is greater in the case of dark malts than in that of pale malts. The authors have investigated three methods with a view to determining the quantity of extract thus lost:—(1) The residues from the laboratory mash were thoroughly washed, dried and mashed again with extract of green malt. (2) The laboratory mash after saccharification was boiled and re-saccharified with extract of green malt. (3) A portion of clear wort was withdrawn from the laboratory mash, the latter was boiled and re-saccharified with the clear portion of the wort. The first method gave rather higher results than the second, whilst the results from the third were very much lower than from the other two. But none of these methods gave the absolute quantity of extractive matter contained in the malt, since further small proportions of extract were obtainable on repeating the treatments.

The influence of the decoction in the brewery mashing would tend to make the practical yield of extract higher than the laboratory yield, were it not that a certain quantity of extract is lost in practice by incomplete sparging. Owing, however, to the possibility of losses by sparging being very much reduced, the authors consider that the decoction principle should be introduced in the laboratory determination of the extract. They recommend the second method above as being most convenient, viz., after the complete saccharification of the laboratory mash, as at present conducted, the whole mash is boiled over a flame for 20 mins.; it is then cooled to 65° C., 10 grms. of an extract of green malt are added, and the mash is maintained at 65°–70° C. for 10 mins. after the second saccharification is complete. The extract of the wort is then determined in the usual way and corrected for the extract of the green malt employed.

—J. F. B.

Cyanogen Iodide: Determination of — in presence of Iodine. J. Milbauer and R. Hac. *Z. anal. Chem.*, 1905, 44, 286–292.

THE qualitative and quantitative determination of cyanogen iodide in presence of iodine is very important in pharmacology on account of its poisonous character.

Meinke (*Z. anorg. Chem.*, 2, 157–174; also this J., 1893, 371) has suggested methods for the determination of the substance which the authors of this paper state are inexact.

The new method devised for the determination of cyanogen iodide depends on the principle that all its iodine is converted into ammonia by the Kjeldahl method. The purity of ordinary commercial iodine was tested by this method, and a trace of cyanogen obtained. Statements which have been made from time to time regarding the occurrence of cyanogen iodide in iodine cannot, therefore, be considered as valid.—C. E. F.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Thorium; Radioactivity of ——. O. Sackur. *Ber. Chem. Ges.*, 1905, 38, 1756–1761.

THE more soluble portions in a fractionation of radium bromide mixture from thorianite gave precipitates with ammonia a substance having the active properties of thorium, but, in a very small degree. The author has attempted by fractional distillation of the chlorides, by adsorption by barium chloride, and by electrolytic methods, to separate this substance from thorianite, and from thorium preparation known origin, and thus to answer the question whether thorium and the new substance independently give the same products of atomic disintegration, or whether the substance, associated in minute quantity with thorium, is the only source of the radio-active properties ascribed to the latter. His results do not decide the question, but, as far as they go, lend support to the latter view, according to which thorium itself is not radioactive.—J. F. B.

Triboluminescence of Arsenious Oxide [and Class of Triboluminescent Reactions.] M. G. Comptes rend., 1905, 140, 1170–1171.

THE luminescence of arsenious oxide is due to the rupture and transformation of crystals after their formation. (Gernez, this J., 1905, 564). The light produced is a continuous spectrum, in the visible part of which yellow and green predominate, though it also contains red. The radiation has a strong photographic action; at a distance its effect is comparable to that of the light of a Bunsen burner at 100 cm. It has no effect on an electro-scope, but seems to be in all respects similar to light emitted by an incandescent solid.

Light is also emitted during the reaction of alkali chlorides or hypobromites, or of solution of alkali powder, under certain conditions of concentration, with nitrogen compounds, such as urea, oxamide, ammonium, ammonium thiocyanate, or asparagin. The light has no special properties, but produces feeble photographic effects. The cause, according to the author, is the production, and immediate decomposition of an alkaline liquid, of nitrogen chloride. Sodium chloride when thrown into hypobromite solution also gives rise to luminescence.—J. T. D.

Hydrogen: Evolution of — by the Action of Concentrated Sodium on Mercury. L. Kahlenberg and H. J. *J. of Phys. Chem.*, 1905, 9, 257–259. *Chem. Zentr.*, 1905, 1, 1365.

METALLIC sodium and mercury react with one another with production of light and flame, and simultaneous evolution of hydrogen. From 1 gm. of sodium, on the addition of 3.24 c.c. of hydrogen are produced, probably owing to the presence of sodium hydride in the metal. L. 1879, found that "pure" distilled sodium gave only one-tenth its volume of hydrogen when heated in vacuo.

Aqueous Solutions; Coefficient of Magnetisation ——. G. Meslin. *Comptes rend.*, 1905, 140, 1320–1331.

THE coefficient of magnetisation of the solid salt separated from the difference between the coefficient of solution and of water, is not a constant, but decreases towards a limit as the solution becomes more dilute. The author's own figures, and also those of other observers, have shown this in the cases of copper sulphate, ferrocyanide, and ferrous sulphate. This is probably due to the ionisation of the dissolved salt. A similar, but somewhat more complex, phenomenon is exhibited by

tures of alcohol and water, the coefficient of which was a maximum value at 96 per cent. of alcohol, while value is the same for absolute alcohol and for a mixture containing 92 per cent. of alcohol. This maximum coefficient is similar to the minimum b. pt. noticed by using 96 per cent. alcohol.—J. T. D.

IX. G. Ciamician and Silber. Ber., 1905, 38, 1671--1675. (See also this, 1901, 844 and 943; 1902, 876 and 1177; 1903, 59 and 14; 1904, 138 and 341.)

the action of light for 5-7 months on a mixture of one and dilute hydrocyanic acid c. 3.3 per cent. length, a product was obtained containing a number of esters, of which the following were isolated:— ammonium cyanide, ammonium oxalate, acetonurea,

oxyisobutyramide $(CH_3)_2C(OH)CONH_2$, and isobutyric acid. The only compound isolated as the product of the action of light on a mixture of cyanide-ammonia and hydrocyanic acid was a compound of the formula, $C_6H_{12}N_3O_3$, probably of the constitution $CH_3CH(COOH)NH.CH(CH_3)CONH_2$. No action was observed on exposing a mixture of benzaldehyde and hydrocyanic acid to light, whilst, under the same conditions, acetaldehyde only yielded a small quantity of an inous compound.—T. F. B.

New Books.

NATURE OF EXPLOSIONS IN GASES. Being the Tenth Lecture, delivered before the Oxford University Junior Scientific Club on June 17, 1903. By ROLAND B. DIXON, M.A., F.R.S. Henry Frowde, Amen Corner, London, E.C.; 12, Frederick Street, Edinburgh; 104, West George Street, Glasgow; 116, High Street, Oxford; 91 and 93, Fifth Avenue, New York; 27, Richmond Street West, Toronto. 1905. Price 3d. nett.

LET, small 8vo. size, containing 33 pages of subject matter, and five plates of engravings.

S D'ANALYSE CHIMIQUE QUANTITATIVE. Par E. ERAL, Professor Agrégé à la Faculté de Médecine et de Pharm. de Lyon. J. B. Baillière et fils, 19, rue de la Harpe, Paris. Price 12 fr.

8vo volume, containing Preface, 843 pages of subject matter, and an alphabetical index of subjects. The text is illustrated with 310 engravings. This work is divided into four parts. In PART I, the special processes of quantitative analysis are described, and they are largely illustrated. PART II. is devoted to the subject of the methods specially employed in quantitative analysis. PART III.—In this, considerable space is devoted to the special Methods of Analysis. (A.) Gravimetric Methods, (B.) Volumetric Methods, and (C.) Physical Methods. PART IV. is devoted to Titrations and Separations of the various Groups, the group of Metalloids, and the determination of the Carbon Group or Organic Compounds.

Trade Report.

I.—GENERAL.

LOCOMOTIVES AND WAGGONS; USE OF — ON LINES OF RAILWAYS IN CONNECTION WITH PREMISES UNDER THE FACTORY AND WORKSHOP ACT, 1901.

Home Office Circular, May 12, 1905.

The Secretary of State proposes to make regulations, with the use of locomotives and waggons on lines

or sidings in or in connection with premises under the Factory and Workshop Act, draft copies of which may be obtained on application to the Factory Department, Home Office, London, or at the local offices of the Inspectors of Factories; any objection with respect to the draft Regulations by or on behalf of any person affected thereby must be sent to the Secretary of State within 40 days from May 12th, 1905. Every such objection must be in writing, and must state (a) the draft Regulations or portions of draft Regulations objected to; (b) the specific grounds of objection; and (c) the omission, addition, or modifications asked for.

III.—TAR PRODUCTS, PETROLEUM, &c.

PETROLEUM PRODUCTION OF BATUM IN 1904.

For. Off. Ann. Series, No. 3366.

The production of crude petroleum at Baku during 1904 was in excess of the production for 1903. In view of the disturbed condition of affairs, however, prevalent during the year in the localities where the wells are situated, and the frequent fires that occurred during the same period, by which large quantities of oil were destroyed, and the subsequent somewhat prolonged strikes, during which the output of oil, except from flowing wells, entirely ceased, the production was brought down to only a little over 2,000,000 barrels in excess of the production of 1903, viz., 73,705,852 barrels, against 71,626,611 barrels. In the early part of 1904, i.e., from January to about the beginning of May, prices of kerosene were fairly high. Later in the year, however, the demand decreased, and a considerable fall in prices followed, with but small shipments from Batoum. Meanwhile Baku continued forwarding kerosene to Batoum, so that towards the autumn the tank storage accommodation at this port was becoming scarce, and at the end of the year the stocks of oil became so enormous that all available reservoirs were full up. Tank storage accommodation at Batoum is estimated at 15,500,000 poods, and the stocks reached nearly 15,000,000 poods.

The total quantity of petroleum products shipped at Batoum in 1904 was:—

To.	1904.	1903.
	Barrels.	Barrels.
Foreign countries	9,261,718	9,415,256
Russia	127,690	502,750

Showing a decrease of 153,538 barrels on exports abroad and of 75,069 barrels on shipments to Russia.

The total number of wells in the Baku oil fields on December 31, last, according to the official statistical information furnished by the Committee of Petroleum Producers, was:—

	1904.	1903.
Producing wells	1,555	1,420
Trial pumping	31	27
Drilling	279	358
Deepening	66	96
Cleaning out and under repair	227	257
Standing idle	1,443	1,276
Total	3,701	3,434

VII.—ACIDS, ALKALIS AND SALTS.

ALKALI, &c., WORKS BILL [No. 227].

Ordered by the House of Commons to be Printed, May 22, 1905.

A Bill to consolidate and amend the Alkali, &c., Works Regulation Acts, 1881 and 1902. Presented by Mr. Gerald Balfour, supported by Mr. Grant Lawson.

The Bill is identical with that presented in May, 1904, and reprinted in this Journal, June 15, 1904, pp. 630-635.

X.—METALLURGY.

MINERALS (OTHER THAN GOLD): OUTPUT OF —, IN WESTERN AUSTRALIA.

Ed. of Trade J., May 25, 1905.

A supplement to the "Government Gazette" of Western Australia contains statistics of the output of minerals (other than gold) in that State during the year 1904 and previous years, from which the following table has been compiled:—

Minerals	1903.		1904	
	Quantity.	Value.	Quantity.	Value.
	Tons.	£	Tons.	£
Black tin	817	55,830	855	58,817
Copper ore	20,526	56,541	3,969	25,180
Ironstone	220	88	1,442	577
Coal	133,427	60,128	138,550	67,174
Limestone	1,280	178	13,397	1,699

IRON CONSUMPTION: GERMANY —.

Eng. and Mining J., May 4, 1905.

The consumption of iron in Germany is estimated by the German Iron and Steel Union on a pig-iron basis. That is, in finding the totals, iron and steel finished products are reduced to the equivalent in pig iron, or to the pig iron consumed in making such products. The statement is as follows, for two years past:—

	1903.	1904.
	Tons.	Tons.
Pig iron production	10,085,634	10,103,941
Pig iron imports	265,422	288,726
Pig iron equivalent of other imports	208,891	252,903
Total supplies	10,559,947	10,645,570
Pig iron exports	527,814	316,255
Pig iron equivalents of other exports	4,269,404	3,628,056
Total exports	4,797,278	3,944,311
Consumption	5,762,669	6,701,259

The average production per head was 171.4 kilos. of pig iron in 1903, and 169.2 kilos. in 1904, a decrease of 2.2 kilos. The average consumption was 97.9 kilos. per head in 1903, and 112.2 kilos. in 1904, an increase of 14.3 kilos. In ten years the average production has increased from 105.1 to 169.2 kilos., and the consumption from 71.9 to 112.2 kilos. of pig iron per inhabitant.

XX.—FINE CHEMICALS, ETC.

CINNAMON CHIPS.

Schimmel's Report, May, 1905, 22.

The total quantity of cinnamon chips exported during the year amounted to 2,135,220 lb., an amount which exceeds any previous return. Of this total, Germany took 692,989 lb.; Great Britain 400,264 lb.; Holland, 268,754 lb.; Belgium, 226,366 lb.; Russia, 130,910 lb.; America, 82,507 lb.; Austria, 79,496 lb.; Australia, 73,608 lb.; France, 18,960 lb., with small amounts to Africa and India.—J. O. B.

CITRONELLA OIL. MARKET POSITION.

Schimmel's Report, May, 1905, 22.

Since last October there has been a great scarcity of citronella oil in the London market, and prices in consequence have risen to 1s. 6d. per lb. In Ceylon, the principal exporters were prevented by heavy contracts in the United States from supplying urgent European demands, and it is only during the past few weeks that large consignments have been advised. The total shipments from Ceylon during 1904 amounted to 1,132,068 lb., as compared

with 1,062,594 lb. in 1903. Of this quantity, the Kingdom received 514,007 lb.; America, 459,211 lb.; Germany, 72,376 lb.; Austria, 47,377 lb.; and France, 9,944 lb. Under the prevailing conditions, there is immediate prospect of prices attaining the low figures of the last few years, since the growing manufacture of citronella and other products absorbs considerable quantities of oil.—J. O. B.

GERANIUM; ESSENTIAL OIL OF —. MARKET POSITION.

Schimmel's Report, May, 1905, 39—41.

In Algeria, an attempt has been made to advance the rate in consequence of the backward state of the market. In Réunion, the prospect has again improved, and shipments point to a heavy production. A widespread tendency to adulterate the oil with palma rosa (East Indian geranium) oil is prevalent, so that exceptionally low quotations should be regarded with suspicion. During 1904, 2034 cases of geranium oil, equivalent to 25,425 kilos., were shipped to Marseilles.

The production of East Indian geranium oil, or palma rosa oil has enormously increased, the large supply available tending to still further depreciate the present market rate. At present prices, palma rosa oil is available as a perfume for many technical purposes.—J. O. B.

LEMON OIL. MARKET POSITION.

Schimmel's Report, May, 1905, 32—34.

The present stock of lemon oil is very low at Marseilles, in consequence of the heavy exports during the past season. The condition of the coming crop indicates a deficit of 10 to 15 per cent. below a normal fruit harvest. Prices for oil during the coming season are, therefore, likely to be higher. The lowest quotation during the present season has been 4.40 marks; from which it has advanced to 5.75 marks, and will probably advance still further. The market is now influenced not only by the supply of material, but by the fact that a successful syndicate, originally formed to control the concentrated lemon juice and calcium citrate industry, is now in the hands of producers of lemon oil in its membership.—J. O. B.

LEMON GRASS OIL. MARKET POSITION.

Schimmel's Report, May, 1905, 54.

The high prices which are prevalent are likely to be diminished production being met with an increasing demand. The stock in Cochin is stated to have fallen to 25 cases; the distilling season being September and October, it is doubtful if the stock now in Europe will last until then. The total shipments from Cochin from July 1st to December 31st, 1904, amounted to 1304 against 1636 in the same period in 1903, and 1414 in 1902. A large proportion of the lemon grass used is absorbed in the production of citral and ionone.—J. O. B.

XXII.—EXPLOSIVES, MATCHES, ETC.

EXPLOSIVES IN COAL MINES. STATUTORY REGULATIONS, 1905, No. 73.

Home Office, Feb. 11, 1905.

The Secretary of State has issued an order dated February 11, 1905, permitting the use of the explosives "abbette," "minite," "monobel powder," and "lite," in addition to those already in use under the provisions of the order of December 20, 1902; April 24, 1903; September 5, 1903; December 10, 1903; and September 6, 1904. The following are the provisions of the schedule:—

Abbette.

Ingredients.	Parts by Weight.	
	Not more than—	Not less than—
Nitrate of ammonium	82.0	78.0
Nitroglycerin	11.0	9.0
Woodmeal (dried at 100° C.)	10.0	8.0
Moisture	2.5	1.0

provisions for its use are as follows:
The explosives shall be used only when contained in a case of stout brown paper thoroughly waterproofed with paraffin wax.

The explosives shall be used only with a detonator electric detonator of not less strength than that known as No. 6, i.e., that the detonator or electric detonator used shall possess an effective detonative strength as great as or greater than that of one containing 15 grs. composition consisting in every 100 parts by weight parts of fulminate of mercury and 20 parts of chlorate of potassium.

The explosive shall have been made at the works of the Compagnie des Salpêtres, near Stanford-le-Dale, Essex, or at the works of the Compagnie des Salpêtres, near Ferrybank, Arklow, Wicklow.

The explosive shall be in all respects similar to the sample submitted to test on December 30, 1904.

The outer package shall bear the words, "As defined in the list of permitted explosives," and the inner package shall be marked with the words, "Permitted explosives used only with not less than No. 6 detonator," and the name of the explosive, the name of the manufacturer, the date and place of manufacture, and the nature and proportion of the ingredients.

Minute.

Ingredients.	Parts by Weight.	
	Not more than—	Not less than—
of ammonium	92.0	87.0
of alcohol	11.0	9.0
of ammonium	2.0	0.5
re	0.5	—

visions 2, 3, and 5 for its use are precisely the same as those of the sample submitted to test on September 23, 1904.

Monobel Powder.

Ingredients.	Parts by Weight.	
	Not more than—	Not less than—
of ammonium	82.0	78.0
lycerin	11.0	9.0
real (dried at 100° C.)	10.0	8.0
te	2.5	0.5

The explosive shall be used only when contained in a case of paper thoroughly waterproofed with ceresin wax.

The explosive, if compressed into a pellet, shall not have a density exceeding 1.3, and each cartridge shall be provided with an axial perforation or cavity of sufficient dimensions to admit of the ready insertion of the detonator. The ends or end of the paper case of each cartridge shall be clearly marked to indicate the position of the said perforation or cavity.

The explosive shall be used only with a detonator electric detonator of not less strength than that known as No. 6 (See 2, abbeite).

The explosive shall have been made at the works of the Compagnie des Salpêtres, near Ferrybank, Arklow, Wicklow, or at the works of the Compagnie des Salpêtres, near Stanford-le-Dale, Essex.

The explosive shall be in all respects similar to the sample submitted to test on October 6, 1903, and other

The outer package shall bear the words "As defined in the list of permitted explosives," and the inner package shall be marked with the words "Permitted explosive used only with not less than No. 6 detonator," and the name of the explosive, the name of the

manufacturer, the date and place of manufacture, and the nature and proportion of the ingredients.

Russische.

Ingredients.	Parts by Weight.	
	Not more than —	Not less than —
Nitroglycerin	42.0	10.0
Nitrocotton	2.75	1.75
Nitrate of potassium	26.0	24.0
Woodmeal (dried at 100° C.)	5.0	3.0
Moisture	1.0	0.0
Carbonate of calcium	0.5	0.0
Oxalate of ammonium	21.0	22.0
Trinitrotoluol	0.5	4.5

1. The explosive shall be used only when contained in a nonwaterproofed wrapper of parchment paper.

2. The explosive shall be used only with a detonator or electric detonator of not less strength than that known as No. 6. (See 2, Abbeite.)

3. The explosive shall have been made at the works of the Compagnie de la Forcite, Baelen Wezel, Belgium.

4. The explosive shall be in all respects similar to the sample submitted to test on September 16, 1904.

5. The outer package shall bear the words "As defined in the list of permitted explosives," and the inner package shall be marked with the words, "Permitted explosive to be used only with not less than No. 6 detonator," and also the name of the explosive, the name of the manufacturer, the date and place of manufacture, and the nature and proportion of the ingredients.

6. The explosive, if in a frozen condition, shall be thoroughly thawed in a safe and suitable manner before use.

EXPLOSIVES; REGULATIONS RESPECTING THE IMPORTATION OF — INTO EGYPT.

Bl. of Trade J., May 18, 1905.

The Egyptian "Journal Officiel" for April 29 contains the text of a Khedivial Decree respecting the importation of, and trade in explosives. The Decree authorises the importation of ammunition for sporting arms, and certain arms for trading purposes, as specified in a list appended to the Decree. The importation of all other explosives (including powder of all kinds, saltpetre, potassium chlorate, dynamite, gun-cotton, nitro-glycerin, fulminates &c.) is prohibited. The prohibition against the importation of explosives does not apply to articles which, in virtue of their composition, are explosive under certain conditions, or which may possibly be used in the manufacture of explosives, as, for example, sulphur, ether, sodium nitrate; it covers only those materials which are intended to be exclusively, or, at least, principally used as quarrying powder or for similar purposes.

The full text of the Decree may be seen at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall Street, London, E.C.

Patent List.

N.B.—In these lists, [A.] means "Application for Patent," and [C.S.] "Complete Specification Accepted."

Where a Complete Specification accompanies an Application, an asterisk is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which acceptances of the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of said date.

18,720 (1904). Wilhehn. *See under XII.*

1156 (1905). Kunz. Dyeing machines. May 31.

COLOURING WOOD, PAPER, LEATHER, Etc.

11,049. Lamb and Rennie. Printing on leather. May 26.

VII.—ACIDS, ALKALIS, AND SALTS.

10,471. Morel and Héritte. Manufacture of borax. May 18.

10,560. Hargreaves. *See under I.*

10,722. Bale. Treatment of the pan scale of salt pans and of its products and apparatus used. May 23.

11,006. Petersson. Production of zinc oxide and metallic tin from scrap or other materials containing these metals. May 26.

12,639 (1904). Robson. Apparatus for vaporising ammonia and reabsorbing ammoniacal and other gases soluble in water. May 24.

13,955 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture and application of reducing agents. May 31.

15,792 (1904). Wrinkle and Wrinkle. Furnaces for use in the manufacture of soda, for the smelting of metals and for like purposes. May 31.

VIII.—GLASS, POTTERY, AND ENAMELS.

10,833. Heller, Baumgarst, and Porzellaufabrik Ph. Rosenthal und Co., Akt.-Ges. Filiale Kronach. Ceramic ware. May 24.

8477 (1905). Handel. Method of ornamenting glass, porcelain, and like articles. May 31.

—BUILDING MATERIALS. CLAYS, MORTARS AND CEMENTS.

10,547. Hoffmann. Manufacture of magnesia cement. May 19.

10,902. Smith and Atherton. Asphalt. May 25.

11,830 (1904). Von Kaufmann and Medberg. Manufacture of artificial stone. May 24.

12,940 (1904). Vokes. Artificial granite and process for the manufacture of the same. May 24.

24,199 (1904). Frugier. Process and apparatus for disintegrating kaolinic stone and the like, and for separating the constituents thereof. May 31.

28,368 (1904). Trapnell and Wood. Manufacture of bricks, tiles, and the like. May 24.

X.—METALLURGY.

[A.] 10,312. Baillot. Cupolas. [Fr. Appd., Dec. 5, 1904.]* May 16.

" 10,469. Ridley. Treatment of slag and apparatus therefor. May 18.

" 10,475. Morgan Crucible Co., Ltd., and McCourt. Treatment of ores or the like for the separation of their constituents. May 18.

" 13,481. Heald. Manufacture of steel or ingot iron. May 18.

" 10,594. Claremont and Stratton. Manufacture of sheet lead. May 20.

" 10,869. MacIvor and Fradd. Process for treating nickel ores or oxidised nickel mattes. May 24.

" 10,881. Vautin and Burt. Production of fused metals from oxides and other compounds. May 24.

" 10,943. MacIvor and Fradd. Process for extracting tin from ore. May 24.

" 10,999. Auchinachie. Extracting gold from sea water. May 26.

" 11,006. Petersson. *See under VII.*

" 11,073. Casman. Process of extracting and refining the copper and alloys of copper contained in ashes, sand, and waste from foundries and other works where copper is dealt with. May 26.

[C.S.] 11,437 (1904). Clark (Goldschmid). Process of and apparatus for refining ores. May 24.

" 14,980 (1904). Lébédoff. Process for smelting sulphuretted copper ores and the simultaneous concentration of the matte. May 24.

" 15,220 (1904). Hadfield. Manufacture or treatment of armour plates or other articles of steel. May 31.

" 15,792 (1904). Wrinkle and Wrinkle. *See under VII.*

" 16,754 (1904). Tyars. Apparatus for treating and amalgamating metals. May 31.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

[A.] 10,888. White and Cowley. Primary batteries. May 24.

" 11,040. Fuller. Electric batteries. May 26.

" 11,056. Fairbrother. Electric accumulator plates. May 26.

[C.S.] 17,011 (1904). Delafon. Voltaic cell. May 24.

" 7101 (1905). De Hemptinne. Apparatus for absorbing gases by a liquid under the action of the silent electric discharge. May 24.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

[A.] 10,326. Buchanan. Apparatus for heating linseed oil. May 16.

" 10,384. Imbert. Soap. May 17.

" 10,387. Fresenius. Purification of fats, fat resins, &c.* May 17.

" 10,437. Brewer and Hardy. *See under XIV.*

[C.S.] 18,720 (1904). Wilhelm. Method of cleaning oil waste and the like. May 31.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

[A.] 10,876. Griffiths. Pigments. May 24.

(B.)—RESINS, VARNISHES.

[A.] 10,387. Fresenius. *See under XII.*

" 11,063. Menge. Driers for oils, paints, lacquer and the like.* May 26.

(C).—INDIA-RUBBER.

- [A.] 10,713. Parkin and Williams. Manufacture of substitutes for india-rubber. May 23.

XIV.—TANNING, LEATHER, GLUE, SIZE, Etc.

- [A.] 10,227. Calico Printers' Association, Ltd., and Warr. Treatment of serum for blood albumen for commercial purposes. May 16.
 „ 10,437. Brewer and Thomas. Process and apparatus for extracting the grease and oil from skins, hides, wool, cotton waste, and other material. May 18.

XVI.—SUGAR, STARCH, GUM, Etc.

- [A.] 10,273. Roy. Treatment of massecuite and apparatus therefor. [Fr. Appl., May 16, 1904].* May 16.
 „ 10,822. Castle. Manufacture of gum tragacanth from locust bean kernels. May 24.
 [C.S.] 15,934 (1904). Stiepel. Manufacture of betaine and its salts from molasses and waste products of beet-root sugar manufacture. May 24.

XVII.—BREWING, WINES, SPIRITS, Etc.

- [A.] 10,198. Worssam. Apparatus for heating or boiling brewers' wort or the like.* May 15.
 „ 10,435. Mislin and Lewin. Manufacture of fusel oils. May 18.
 „ 10,783. Hyde. Process of brewing and appliances employed therewith. May 23.
 [C.S.] 4271 (1904). Oppenheimer and Kent. Spirituous fluid or compound and process for obtaining the same. May 31.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A).—FOODS.

- [A.] 10,303. McDonnell. Process for preserving milk. May 16.
 „ 10,847. Bower and Phillips. Apparatus for desiccating milk and similar liquids. May 24.
 „ 11,131. Bonnicart (Evangelidi). Process of preserving eatables.* May 27.
 [C.S.] 6278 (1904). Poumay. Alimentary product and process for the manufacture thereof. May 31.

(B).—SANITATION; WATER PURIFICATION.

- [A.] 10,382. Commin. Installation for the septic tank treatment of sewage.* May 17.
 „ 10,679. Ridley. Preparation of slag suitable for use in bacteria beds. May 22.
 [C.S.] 15,829 (1904). Middleton. Filter and contact beds for the bacterial treatment of sewage. May 24.
 „ 5274 (1905). Smith. Compounds for removing incrustation from boilers and the like. May 24.

(C).—DISINFECTANTS.

- [A.] 10,824. Gyr. Sheep dipping compounds. May 16.
 „ 10,825. Gyr. Insecticide and fungicide. May 16.

XIX.—PAPER, PASTEBOARD, Etc.

- [A.] 10,319. Garbin, Gérard and Gérard. Process and apparatus for utilising the waste of cellulose and similar substances.* May 16.
 „ 10,880. Boulton (Moritz and Moritz). Paper making apparatus.* May 24.
 [C.S.] 15,435 (1904). Gardner (Chem. Fabr. v. Weiler-ter-Meer). Process for producing substances resembling celluloid. May 24.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 10,201. Chem. Fabr. von Heyden Act.-Ges. Manufacture of guanidyl dialkylbarbituric acids. [Fr. Appl., July 14, 1904].* May 15.
 „ 10,436. Mislin and Lewin. Method for manufacturing lactic acid for technical purposes. May 18.
 „ 10,758. Behal. Manufacture of camphor, borneols and camphors.* May 23.
 „ 10,927. Angier. Process for the production of bisulphide of carbon. [Ger. Appl., May 1, 1904].* May 25.
 „ 10,976. Merck, Merck and Merck. Manufacture of guanines from cyanamido-4,5-diamidoxypyrimidine and its homologues. [Ger. Appl., July 19, 1904].* May 25.
 „ 11,058. Sommer. Production of anhydrides of organic acids. May 26.
 [C.S.] 14,014 (1904). Boehm (Merck). Manufacture of barbituric acids and intermediate products. May 31.
 „ 15,934 (1904). Stiepel. See under XVI.
 „ 22,129 (1904). Merck, Merck and Merck. Separation of pyrimidines. May 24.
 „ 2787 (1905). Mayer. Method of preparing diet malonylurea. May 24.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 10,372. Smith. Manufacture of films for photographic and other purposes. [Ger. Appl., May 18, 1904].* May 17.
 „ 10,900. Grün and Smith. Producing photographic prints in natural colours from negatives obtained by the ordinary trichromatic system of photography. May 25.
 „ 11,077. Pfanz. Preparation of photographic printing papers or surfaces.* May 26.
 [C.S.] 6276 (1905). Smith. Reducing agents or compositions for use in photography. May 24.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 10,901. Le Sueur. Explosive. May 25.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

- [A.] 11,067. Martin. Estimation of the quantity of oil contained in feed water.* May 26.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 12.—Vol. XXIV.

JUNE 30, 1905.

No. 12.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21 -;
Election by the Council.

Price to Non-Members 36 - per annum;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each; 1902 *et seq.*, 1 0 each.

he Society of Chemical Industry.

Past Presidents :

Sir Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Sir Frederick A. Abel, Bart., K.C.B., G.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
V. H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
T. K. Muspratt	1885—1886.
David Howard	1886—1887.
Sir James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.
Emerson Reynolds, M.D., F.R.S.	1891—1892.
Sir John Evans, K.C.B., D.C.L., LL.D., Sc.D., F.R.S.	1892—1893.
E. C. C. Stanford	1893—1894.
E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyer,	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Bellby	1898—1899.
F. Chandler, D.Sc., M.D., Ph.D., LL.D. Sir Jos. W. Swan, D.Sc., M.A., F.R.S.	1899—1900.
Ivan Levinstein	1900—1901.
Wm. Ramsay, K.C.B., D.Sc., LL.D., F.R.S.	1901—1903.
† Deceased.	1903—1904.

COUNCIL FOR YEAR ENDING JULY 1905.

President : Wm. H. Nichols, M.S., LL.D., D.Sc.

Vice-Presidents :

Phyllips Bedson.	Ivan Levinstein.
Reginald Coblenz.	Max Muspratt.
Edw. Divers, F.R.S.	T. J. Parker.
V. R. E. Hodgkinson.	Dr. F. B. Pinner.
Edw. Hooper.	Sir Wm. Ramsay, K.C.B., F.R.S.
David Howard.	Thos. Tyer.

Ordinary Members of Council :

Grossmann.	B. E. R. Newlands.
Bottmann.	Prof. W. J. Pope, F.R.S.
Longway.	Dr. Boverton Redwood.
V. R. Lang.	Walter F. Reid.
Leuckowitsch.	Frank Scudder.
Martin.	Dr. W. S. Storer.

Sectional Chairmen and Secretaries :

BIRMINGHAM.	
Frederick F. Frankland, F.R.S.	F. R. O'Shaughnessy.

Birmingham Section.

Chairman: Percy F. Frankland.

Vice-Chairmen:

W. Waters Butler, Frank E. Lott, Alex. E. Tucker.

Committee:

Robt. B. Batty.	Edward Jackson.	T. Slater Price.
Wm. B. Davidson.	Thos. Lawton.	Walter Rosenhain.
Alex. Findlay.	Alex. McKenzie.	Harry Silvester.
Henry L. Heathcote.	Frank Platten.	Thos. Turner.

Hon. Local Secretary and Treasurer:

F. R. O'Shaughnessy, Tyburn, nr. Birmingham.

Canadian Section.

Chairman: F. J. Smale.

Vice-Chairmen: W. H. Ellis, Thos. Macfarlane.

Committee:

J. Watson Bain.	W. L. Goodwin.	W. Lash Miller.
Jeffrey H. Burland.	W. R. Lang.	Jas. P. Murray.
Thos. Davies.	A. McGill.	Harold Vander Linde.
G. P. Girdwood.		

Hon. Treasurer: M. J. Taylor, 77, Front Street East, Toronto

Hon. Local Secretary:

Alfred Burton, 42, Front Street West, Toronto.

Liverpool Section.

Chairman: Eustace Carey.

Vice-Chairman: Frank Tate.

Committee:

T. Lewis Bailey.	G. Watson Gray.	Alf. Sneath.
G. C. Clayton.	C. Longuet Higgins.	H. B. Stocks.
J. T. Conroy.	Max Muspratt.	J. W. Towers.
A. Foden.	E. L. Peck.	

Hon. Treasurer: W. P. Thompson.

Hon. Local Secretary:

W. R. Hardwick, 13, Batavia Buildings, Hackins Hey, Liverpool.

The following take office in July next:—*Committee:* Arthur Carey, J. Campbell Brown, Herbert E. Davies, and W. Collingwood Williams

London Section.

Chairman: A. Gordon Salamon.

Vice-Chairman: R. J. Friswell.

Committee:

H. G. Colman.	D. L. Howard.	Walter F. Reid.
J. N. Connah.	J. Leukotsch.	L. T. Thorne.
Bernard Dyer.	A. R. Ling.	Thos. Tyler.
Oscar Guttman.	Wm. Pearce.	Chas. Wightman.
J. T. Hewitt.	Boverton Redwood.	

Hon. Local Secretary: Julian L. Baker, 7, Addison Road, Bedford Park, W.

The following take office in July next:—*Committee:* E. J. Bevan, M. O. Forster, G. C. Jones, B. E. R. Newlands, and F. Napier Sutton.

Manchester Section.

Chairman: J. Carter Bell.

Vice-Chairman: F. Scudder.

Committee:

J. Allan.	G. J. Fowler.	K. Markel.
J. Bürger.	J. Grossmann.	W. J. Pope.
R. Clayton.	B. Hart.	H. Porter.
W. H. Coleman.	W. B. Hart.	W. Thomson.

Hon. Local Secretary:

Julius Hübner, Ash Villa, Cheadle Hulme, Cheshire.

The following take office in July next:—*Chairman:* G. H. Bailey. *Committee:* J. Barnes, R. S. Hutton, W. E. Kay, J. H. Lester, and F. Stenhouse.

Newcastle Section.

Chairman: J. T. Dunn

Vice-Chairman: W. L. Rennoldson.

Committee:

P. P. Begson.	N. H. Martin.	Harry Smith.
H. S. Collins.	John Pattinson.	A. Spiller.
Ellwood Holmes.	W. W. Proctor.	J. E. Stead.
H. Louis.	Geo. Sisoo.	C. E. Stuart.

Hon. Local Secretary and Treasurer:

F. C. Garrett, Armstrong College, Newcastle-on-Tyne.

The following take office in July next:—*Chairman:* H. Louis. *Vice-Chairman:* J. T. Dunn. *Committee:* W. L. Rennoldson.

New England Section.

Chairman: Henry Howard.

Vice-Chairman: F. E. Atteaux.

Committee:

C. R. Borland.	J. W. Loveland.	F. C. Robins
A. A. Clafin.	L. A. Olney.	Charles R. Sa
W. A. Gallup.	Edw. D. Pearce.	F. H. Thorp
A. F. Hobbs.	A. Reuter Dahl.	W. J. Webb
Lawrence S. James.		

Hon. Local Treasurer: Godfrey L. Cabot.

Hon. Local Secretary:

Wm. H. Walker, 93, Broad Street, Boston, Mass., U.S.A.

New York Section.

Chairman: Russell W. Moore.

Vice-Chairman: Geo. C. Stone.

Committee:

L. Baekeland.	A. H. Elliott.	Wm. H. Nieho
Chas. Baskerville.	E. G. Love.	T. J. Parker.
Chas. F. Chandler.	Wm. McMurtrie.	F. Schnerwind.
V. Coblentz.	H. A. Metz.	C. B. Zabriski
G. Drobegg.		

Hon. Treasurer: R. C. Woodcock.

Hon. Local Secretary:

H. Schweitzer, 40, Stone Street, New York, U.S.A.

The following take office in July next:—*Committee:* Laguel Haigh, A. C. Humphreys, Edmund H. Miller, G. Prochazka, and Walter E. Rowley.

Nottingham Section.

Chairman: J. T. Wood.

Vice-Chairman: S. F. Burford.

Committee:

L. Archbutt.	F. Stanley Kipping.	A. L. Stern.
F. J. R. Carulla.	H. B. Mayfield.	G. J. Ward.
R. M. Caven.	J. O'Sullivan.	J. White.
J. Golding.	J. M. C. Paton.	

Hon. Treasurer: S. J. Pentecost.

Hon. Local Secretary:

S. R. Trotman, King's Walk Chambers, Parliament St Nottingham.

The following take office in July next:—*Chairman:* J. Paton. *Vice-Chairman:* J. T. Wood. *Committee:* Burford, H. S. Garry, and O. Quibell.

Scottish Section.

Chairman: R. T. Thomson.

Vice-Chairman: J. S. Macarthur.

Committee:

W. S. Curphey.	G. H. Gemmell.	W. G. Johnst
L. Dobbin.	R. Hamilton.	J. Falconer E.
D. B. Dott.	Jas. Heedrick.	M. A. Parker.
Thos. Ewan.	Jas. Hope.	T. L. Patters
J. Arnold Fleming.	H. Ingle.	D. J. Playfair
W. Frew.		

Hon. Secretary and Treasurer:

Thomas Gray, c/o Gourlay and Deas, 180, Hope Street, Glasgow.

The following take office in July next:—*Chairman:* Perry. *Committee:* Robt. M. Clark, Chas. E. Fawcitt, J. S. Ford, G. G. Henderson and Jas. McLeod.

Sydney, N.S.W., Section.

Chairman: A. Liversidge.

Committee:

W. A. Dixon.	J. Morison.	R. Greig Smil
J. F. Elliott.	A. A. Ramsay.	H. G. Smith.
L. Meggitt.	J. A. Schofield.	T. Steel.

Hon. Local Secretary:

T. U. Walton, Colonial Sugar Co., O'Connell Street, Sydney, N.S.W.

The following take office in July next:—*Committee:* V. G. C. Joplin and J. M. Petrie.

Yorkshire Section.

Chairman: H. R. Procter.

Vice-Chairman: G. W. Slatter.

Committee:

C. S. Bedford.	John W. Cobb.	A. Smithells.
J. E. Bedford.	W. M. Gardner.	Geo. Ward.
F. Branson.	F. W. Richardson.	Thorp Whitak
B. A. Burrell.		

Hon. Local Secretary and Treasurer:

T. Fairley, 17, East Parade, Leeds.

The following take office in July next:—*Vice-Chairman:* Whitaker. *Committee:* Saml. H. Davies, H. B. Hirst, W. Mackey and G. E. Scott-Smith.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of property of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be retracted for the Journal, in which case no reprints can be furnished to the author.

ANNUAL GENERAL MEETING, 1905.

The Annual General Meeting will be held in London on July next, and the proceedings will commence on Monday, July 10th.

In accordance with the provisions of Rule 18 of the Bye-laws, notice is hereby given that those members whose names are printed in *italics* in the list of Council retire from their respective offices at the forthcoming Annual Meeting.

Mr. Edward Divers, F.R.S., has been nominated to the office of President under Rule 8; Dr. L. Baekeland, J. Carter Bell, Dr. J. Lewkowitzsch, and Mr. N. H. Martin have been nominated Vice-Presidents under Rule 8; and Mr. Wm. H. Nichols has been nominated a Vice-President under Rule 11.

The Hon. Treasurer and Hon. Foreign Secretary have been nominated for re-election to their respective offices. Mr. J. Bingham Alliot, Dr. J. T. Dunn, Mr. A. R. Ling, J. S. McArthur, Dr. K. E. Markel, and Mr. Charles Taylor have been nominated under Rule 18 to fill vacancies among the Ordinary Members of Council. Ballot List, Member's Ticket, Supplementary Programme, and Request were issued with the June 15th number.

The Hon. Treasurer's Annual Statement and audited Balance-sheet are contained in this number.

BIRMINGHAM SECTION.

The Birmingham Section of the Society, after an interval of some years, has resumed active work. Meetings will be held at the University, and Prof. F. Frankland, F.R.S., has accepted the chairmanship with Mr. F. R. O'Shaughnessy as Hon. Local Secretary and Treasurer.

NEW ENGLAND SECTION.

The New England Section held its inaugural meeting in Boston, Mass., on May 12th. Between 80 and 90 members were present, including the President of the Society, with Dr. H. Schweitzer, Mr. T. J. Parker, and other representatives of the New York Section.

CONGRESS OF CHEMISTRY AT LIÈGE.

In connection with the Liège Exhibition, a Congress of Chemistry and Pharmacy will be held from the 27th to the 30th July next. By a subscription of 10 francs, members may take part in the Congress, and will receive copies of the transactions. Application for Adhesion and programmes should be made at once to M. J. Mond, Pharmacien, Liège, or M. J. Wanters, Chimiste, at de la Ville de Bruxelles.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. Communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

List of Members Elected.

June 23rd, 1905.

- Amory, L. H., c/o Messrs. J. Heathcoat and Co., Tiverton, Devon, Lace Manufacturer.
- Andrae, Dr. E. P., Crestalba, Champion Hill, London, W. S.E., Chemist.
- Baker, Henry, 18, Booth Street, Manchester, Secretary.
- Barker, Perry, c/o F. W. Matthiessen, jun., La Salle, Ill., U.S.A., Chemist.
- Broemmel, Geo. M., 2501, California Street, San Francisco, Cal., U.S.A., Chemist.
- Brown, Nicol, 4, The Grove, Highgate, N., Mining Director.
- Clayton, W. E., Royal Victoria Yard, Deptford, S.E., Superintendent.
- Davidson, Frank A., 182, Mount Vernon Street, West Roxbury, Mass., U.S.A., Pharmaceutical Chemist.
- Derby, Wallace G., Laurel Hill, Queensboro, New York City, U.S.A., Assayer.

We have compared the above statement with the vouchers, counterfoils of the receipts issued and other records, and are of opinion it correctly exhibits the cash transactions of the Society for the year 1904. The amounts of the Metropolitan 3 per cent consolidated, 3 per cent. New Zealand and 3 per cent. New South Wales Stocks have been confirmed by the Chief Accountant to the Bank of England. Certificates for the remaining investments have been inspected and the Bank Balances have been certified by the Bankers.

23, St. Swithin's Lane, London, E.C.

MR. A. GORDON SALAMON IN THE CHAIR.

AZO-COLOURING MATTERS DERIVED FROM AR-TETRAHYDRO-*a*-NAPHTHYLAMINE.*

BY GILBERT T. MORGAN, D.S.C., AND F. E. RICHARDS.

Although naphthalene was long ago shown to consist of two conjugated benzene rings, yet it was almost as soon recognised that the behaviour of this hydrocarbon was usually by no means strictly comparable with that of benzene and its homologues (toluene, xylene, &c.), the bicyclic hydrocarbon being generally found to be chemically more reactive than its unicyclic prototype.

Bamberger's classical researches on the hydrogenation of the naphthylamines and the naphthols showed that

the characteristic properties of the naphthalene eos are due to the mutual influence of the two unsaturated rings and that the hydrogenation of one of these systems brings about a reversion to the benzenoid (Ber. 1888, 21, 847, 1112, 1786, 1892; 1889, 22, 1295; Ber. 1890, 23, 197, 876).

Recently this interesting case of chemical atavism formed the subject of a series of investigations emanating from the chemical laboratory of the Royal College of Science, and, in the course of this work, Dr. C. S. showed (Journ. Chem. Soc. 1902, 81, 900, and 1904, 728, 732) that contrary to the experimental evidence adduced by Bamberger and Bordt (Ber. 1890, 23, 3) *ar*-tetrahydro-3-naphthylamine does not yield derivatives by the direct action of diazonium salts, resembles aniline, *p*-toluidine and their homologues forming intermediate diazoamines and also behaves in other respects just like a benzenoid amine. In this, therefore, the disappearance of naphthalenoid properties is complete.

On the other hand one of the authors in conjunction with Miss Micklethwait and Mr. Winfield (Journ. Chem. Soc. 1904, 85, 736) substantiated Bamberger and Althausse's statement (Ber. 1888, 21, 1786) that tetrahydro-*a*-naphthylamine at once yields azo-compounds and does not, under the conditions usually employed, these condensations, give rise to intermediate diazoamines. Hence, in this respect, the base retains its naphthalenoid character, although towards other reagents it exhibits the behaviour of aniline and its homologues (Bamberger *loc. cit.*). The tinctorial properties of *ar*-tetrahydro-naphthylamineazobenzenesulphonic acid and other azo-compounds have been found to differ considerably from those of the corresponding derivatives of *a*-naphthylamine and the above mentioned authors proved that dissimilarity must be ascribed to the hydrogenation of the unsubstituted ring and not to a difference in the orientation of the azo-groups (Journ. Chem. Soc., 1904, 85, 754). The foregoing sulphonated azo-derivative of *ar*-tetrahydro-*a*-naphthylamine was shown (Morgan, Micklethwait and Winfield *loc. cit.* p. 754) to be a para-compound just like its analogue obtained from *a*-naphthylamine.

This fact brings *ar*-tetrahydro-*a*-naphthylamine into the category of aromatic bases which yield directly *p*-azo-compounds capable of being diazotised and combined with various phenols and amines to form dyestuff-colouring matters.

Although at present the cost of the materials (ethyl alcohol and sodium) required in preparing *ar*-tetrahydro-*a*-naphthylamine from *a*-naphthylamine precludes the possibility of employing the base in the manufacture of azo-dyes, yet it seems desirable to place on record the fact that such colouring matters may readily be obtained, and accordingly some representative examples of these substances have been prepared and compared with their analogues in the benzene and naphthalene series.

In connection with this question of the cost of production, the remarkable results obtained by Sabatier and Senderens in hydrogenating aromatic substances with hydrogen in the presence of nickel should be noted, for these authors have announced the production of tetrahydronaphthalene from naphthalene by this process (Comptes rend., 1901, 132, 1254). Should it be found possible to extend this reaction to the preparation of azoamines and phenols of the tetrahydronaphthalene series, then the employment of these substances in the manufacture of artificial colouring matters might become practicable.

I.—Azo- and Disazo-derivatives of *ar*-Tetrahydro-*a*-naphthylamine.

1.—*ar*-Tetrahydro-*a*-Naphthylamineazobenzenesulphonic acid ($\text{NH}_2\cdot\text{C}_{10}\text{H}_{10}\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{H}$) (Ber. 1889, 22, 1295; Journ. Chem. Soc. 1905, 85, 743), is a well-defined compound, the sodium salt of which crystallises in brown orange scales. It dyes wool in an orange shade from an acid bath, thus differing considerably from the corresponding *a*-naphthylamine derivative $\text{NH}_2\cdot\text{C}_{10}\text{H}_8\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{Na}$ which gives a chocolate brown colour.

* Taken as read.

Disazo-colouring matter with Chromotrope acid.—The foregoing azo-sulphonic acid when suspended in hydrochloric acid and treated with sodium nitrite yields a disazo-derivative the aqueous suspension of which, when poured into a sodium carbonate solution of 2,6-dihydroxynaphthalene-3:6-disulphonic acid gives to the disazo-compound $\text{SO}_3\text{Na} \cdot \text{C}_{10}\text{H}_4 \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_{10} \cdot \text{C}_{10}\text{H}_3(\text{OH})_2(\text{SO}_3\text{Na})_2$ which being only moderately soluble in cold water is readily salted out.

When dyed on wool from an acid bath this disazo-derivative gave reddish-violet to violet blue shades thus differing from the corresponding naphthalene derivative $\text{SO}_3\text{Na} \cdot \text{C}_6\text{H}_4 \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_6 \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_3(\text{OH})_2(\text{SO}_3\text{Na})_2$ which gave a much more intense black shade.

Disazo-colouring matters with "R salt" and with Naphthol-4-sulphonic acid.—The disazo-compound

$\text{SO}_3\text{Na} \cdot \text{C}_6\text{H}_4 \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_{10} \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_4(\text{OH})(\text{NaSO}_3)_2$ obtained by a process similar to that employed in production of the preceding compound; it dyes wool dark reddish brown shades.

The disazo-compound similarly produced from α -naphthol-4-sulphonic acid, gives a dark red shade on wool dyed in an acid bath. In each case the colour produced by the tetrahydronaphthalene derivative was found to be redder and brighter than that obtained with the corresponding naphthalene derivative.

The foregoing three disazo-colouring matters resemble their tinctorial properties, the analogous disazo-compounds of aminoazobenzene and its toluene and xylene homologues, and thus furnish additional evidence of the azo character of *ar*-tetrahydro- α -naphthylamine.

*Naphthaleneazo- α -*ar*-tetrahydro- α -naphthylamine.*— $\text{C}_{17}\text{H}_{16}\text{N}_2\text{O} \cdot \text{C}_{10}\text{H}_{10} \cdot \text{NH}_2$ isomeric with tetrahydronaphthaleneazo- α -naphthylamine (Bambeyer and Bordt, Ber., 1904, 22, 625) was prepared by diazotising α -naphthylamine and combining the diazo-salt with the tetrahydro- α -naphthylamine; it separated from methyl alcohol in reddish black crystals. 0.1986 gave 23.7 c.c. nitrogen at 22° and 765 mm.; N=13.93 per cent.

$\text{C}_{20}\text{H}_{19}\text{N}_3$ requires N=13.95 per cent.

This compound dissolves in concentrated sulphuric acid yielding a violet coloration, whereas its isomeric α -naphthylamine yields a dull violet solution.

p-Nitrobenzeneazo- α -*ar*-tetrahydro- α -naphthylamine, $\text{C}_6\text{H}_4 \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_{10} \cdot \text{NH}_2$ is a well defined azo-base, formed by adding an acetic acid solution of *p*-nitrobenzenediazonium chloride to an alcoholic or acetic acid solution of *ar*-tetrahydro- α -naphthylamine; the hydrochloride at once separates as a dark red microcrystalline precipitate, from which the base is liberated by ammonia. It is an azoamine when crystallised from ethyl acetate in dark brown flakes. 0.1439 gave 23 c.c. nitrogen at 21.5° and 771 mm.; N=18.84.

$\text{C}_{16}\text{H}_{16}\text{O}_2\text{N}_4$ requires N=19.03 per cent.

*Tetrahydro- α -naphthaleneazo- α -*ar*-tetrahydro- α -naphthylamine*

Prepared by diazotising the tetrahydro-base and combining the diazo-compound with another molecular portion of the base in acetic acid solution, separates on the addition of aqueous sodium acetate and crystallises from ethyl acetate in brownish orange needles melting at 35°–140°. 0.2602 gave 30.6 c.c. nitrogen at 19° and 771 mm.; N=13.63.

$\text{C}_{20}\text{H}_{23}\text{N}_3$ requires N=13.77 per cent.

*Substantive Polyazo-colouring matters derived from α -*ar*-tetrahydro- α -naphthylamine.*

These substances result from the combination of the azotised para-diamines (benzidine, tolidine, dianisidine) with one or two molecules of *ar*-tetrahydro- α -naphthyl-

amine; the intermediate aminoazo-compounds being subsequently diazotised and then condensed with the sulphonic acids of various amines and phenols.

1. *Di- α -*ar*-tetrahydro- α -naphthylamine.*—When a hydrochloric acid solution of *ar*-tetrahydro- α -naphthylamine (2 mols.) and the diazonium chloride from tolidine is treated with aqueous sodium acetate, the aminoazo-derivative

is obtained as a dark brown insoluble product; it dissolves in alcohol to an orange-brown solution; its hydrochloride is a black powder sparingly soluble in water and dissolving in alcohol to a purple solution. The polyazo-colouring matter,

obtained by diazotising the preceding hydrochloride and combining it with chromotrope acid, and the allied azo-compound from α -naphthol-4-sulphonic acid are black powders with a metallic lustre, sparingly soluble in cold water to a reddish-violet solution and developing intense blue colorations with concentrated sulphuric acid. The former gives greyish-blue shades on un mordanted cotton, whilst heliotrope tints are obtained with the latter.

2. The intermediate diazo-compound obtained by combining tetrazotised tolidine with one molecular proportion of *ar*-tetrahydro- α -naphthylamine, when again diazotised and coupled with chromotrope acid, yields a more soluble polyazo-compound, which dyes un mordanted cotton in a dark blue shade.

If the preceding diazo-derivative is coupled with α -naphthol-4-sulphonic acid, it yields a polyazo-compound which dyes un mordanted cotton in a reddish heliotrope shade.

III.—*Azo-derivatives of α -*ar*-tetrahydro- α -naphthylamine-4-sulphonic acid.*

1. As recently shown (Journ. Chem. Soc., 1904, 85, 755), *ar*-tetrahydro- α -naphthylamine on sulphonation yields tetrahydro- α -naphthylamine-4-sulphonic acid $\text{NH}_2 \cdot \text{C}_{10}\text{H}_{10} \cdot \text{SO}_3\text{H} \cdot \text{H}_2\text{O}$, a substance closely resembling sulphanilic acid and which, when diazotised and combined with β -naphthol yields sodium β -naphtholazotetrahydronaphthalenesulphonate, $\text{HO} \cdot \text{C}_{10}\text{H}_6 \cdot \text{N}_2 \cdot \text{C}_{10} \cdot \text{SO}_3\text{Na}$, this azo-derivative readily separating as a bright red precipitate on adding to its solution a small amount of salt.

Comparative dye tests with Naphthol Orange, $\text{HO} \cdot \text{C}_{10}\text{H}_6 \cdot \text{N}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{Na}$ and Fast Red, $\text{HO} \cdot \text{C}_{10}\text{H}_6 \cdot \text{N}_2 \cdot \text{C}_{10}\text{H}_6 \cdot \text{SO}_3\text{Na}$ showed that the tetrahydronaphthalene derivative resembles the former dye in tinctorial properties. It dyes wool from an acid bath in bright orange shades which are distinctly redder than those from Naphthol Orange, but differ entirely from the shades of colour obtained with Fast Red.

3. Sodium dimethylanilineazo-tetrahydronaphthalene-4-sulphonic acid is prepared by the interaction of diazo-tetrahydronaphthalene-4-sulphonic acid with dimethylaniline, and is a brown-orange powder having tinctorial properties resembling those of its benzene analogue, Methyl Orange.

3. Sodium 2:7-Dihydroxynaphthaleneazo-tetrahydronaphthalene-4-sulphonate.—

is prepared by the interaction of diazotetrahydro- α -naphthalene-4-sulphonic acid with 2:7-dihydroxynaphthalene, and separates from solution on the addition of a small quantity of sodium chloride; it dyes wool in a reddish-brown shade from acid bath, the colour produced differing considerably from that of Roxamine, its naphthalenoid analogue.

4. Sodium 3:6 disulpho-1:8-dihydroxynaphthaleneazotetrahydronaphthalene-4-sulphonate, prepared by the interaction of diazotetrahydro- α -naphthalenesulphonic acid with chromotropic acid, separates out on the addition of potassium chloride. In this case the fractional precipitation of the dye with potassium chloride leads to the separation of two substances, one dyeing wool in brownish-red, and the other producing a dark reddish-purple shade.

5. 4-sulpho-1:1-dihydroxynaphthaleneazotetrahydronaphthalene-4-sulphonic acid.

is prepared by the interaction of diazotetrahydronaphthalene-4-sulphonic acid and Nevil and Winter's acid, and separates best in the form of its calcium salt; it dyes wool from an acid bath in brown shades, thus differing from the colour obtained with Fast Red C, its naphthalenoid analogue.

IV. Azo-Derivatives of Dimethyl- α -tetrahydro- α -naphthylamine.

The dimethyl- α -tetrahydro- α -naphthylamine required in these experiments was prepared by heating α -tetrahydro- α -naphthylamine hydrochloride with methyl alcohol under pressure at $170-180^\circ$. This tertiary base, unlike dimethylaniline, does not show any tendency to condense with formaldehyde or benzaldehyde, but nevertheless retains the property of coupling with diazonium salts.

1. *p*-Nitrobenzenediazodimethyl- α -tetrahydro- α -naphthylamine $\text{NO}_2\cdot\text{C}_6\text{H}_4\cdot\text{N}_2\cdot\text{C}_{10}\text{H}_{10}\cdot\text{N}(\text{CH}_3)_2$ produced by coupling the base with *p*-nitrobenzenediazonium chloride in the presence of excess of aqueous sodium acetate crystallises from alcohol or ethyl acetate in well-defined, deep red acicular prisms melting at $150-152^\circ$. 0.1497 grm. gave 21.4 c.c. nitrogen at 21° and 766 mm. $\text{N}=16.78$. $\text{C}_{15}\text{H}_{18}\text{O}_2\text{N}_4$ required $\text{N}=17.28$ per cent.

2. Sodium Dimethyl- α -tetrahydro- α -naphthylamineazobenzenesulphonate $\text{N}(\text{CH}_3)_2\cdot\text{C}_{10}\text{H}_{10}\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{Na}$ prepared by coupling the tertiary base with diazobenzenesulphonic acid, separates from its aqueous solution on the addition of alcohol in yellow-brown flakes.

For purposes of comparison the naphthalenoid analogue of the foregoing compound was prepared from dimethyl- α -naphthylamine and diazobenzenesulphonic acid.

Sodium dimethyl- α -naphthylamineazobenzenesulphonic acid separates from its concentrated aqueous solution in brown flakes on the addition of sodium chloride.

The tinctorial properties of these two azo-compounds were compared. The colours obtained on wool showed that the isomeric tetrahydronaphthalene compounds $\text{N}(\text{CH}_3)_2\cdot\text{C}_{10}\text{H}_{10}\cdot\text{H}_2\cdot\text{C}_{10}\text{H}_7\cdot\text{SO}_3\text{Na}$ (see page 653) and $\text{N}(\text{CH}_3)_2\cdot\text{C}_{10}\text{H}_{10}\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{Na}$ give reddish-orange shades on wool from an acid bath, whereas the naphthalene derivative $\text{N}(\text{CH}_3)_2\cdot\text{C}_{10}\text{H}_6\cdot\text{N}_2\cdot\text{C}_6\text{H}_4\cdot\text{SO}_3\text{Na}$ furnishes a brown colour.*

CONCLUSIONS.

1. α -Tetrahydro- α -naphthylamine retains its naphthalenoid character and resembles α -naphthylamine in yielding directly aminoazo-compounds which can be readily diazotised and coupled with suitable sulphonated amines or phenols to form polyazo-colouring matters.

2. The azo- and disazo-colouring matters derived from α -tetrahydro- α -naphthylamine and its sulphonic acid and dimethyl derivative have tinctorial properties very similar to those of their analogues of the benzene series, and differ markedly in this respect from the corresponding compounds in which the naphthalene residue is substituted for the tetrahydronaphthalene complex.

ANALYSIS OF SILICON (GRAPHITIC) AND SILOXICON.*

(From the Acheson Carborundum Works, Niagara, U.S.A.)

BY PERCY E. SPIELMANN, A.R.C.Sc., A.I.C.

Analysis of a Sample of Silicon.

The sample contained silicon, silica, iron, aluminium, and alumina. An occasional crystal of carborundum was found, and not included in the analysis.

The substance was heated in a porcelain boat in a stream of chlorine, whereby the silicon, iron, and aluminium were volatilised as chlorides. They were absorbed by being passed over the surface of water in a flask, and through a U-tube loosely packed with wet cotton the silicon tetra-chloride being decomposed to the hydroxide. In this way there was no loss of gases, as was seen when pure water was employed in the place of wet cotton wool. After the ferric chloride was volatilised the combustion tube was blow-piped as strongly as it was safe to do; the reaction was known to be at an end by the contents of the boat ceasing to glow. Only silicon chloride and a negligible amount of ferric chloride absorbed by the cotton wool, which was burned off in the oxides.

The separation of the silicon, iron, and aluminium was carried out as usual. The residue of silica and alumina left in the boat was fused with acid potassium sulphate, and their amounts estimated.

This analysis gave:—

Si	93.91	per cent.
Fe	2.57	"
Al	0.41	"
SiO ₂	2.65	"
Al ₂ O ₃ (by diff.)	0.46	"
					100.00	"

Other attempts at analysis brought out the following facts:—Hydrofluoric acid with sulphuric acid has no effect; nor has boiling bromine, nor fused potassium nitrate. Fusion mixture acts well on the substance, but a suitable crucible is not obtainable, because the fusion mixture attacks porcelain and the silicon attacks metals, including platinum.

The specific gravity of the substance was found to be 1.90.

Analysis of a sample of Siloxicon.

Siloxicon is a greenish-grey substance, easily reduced to a coarse powder in the fingers, and contains shining particles distributed throughout its mass. It can be separated, though not quantitatively, and is able to scratch glass; they consist of carborundum and with graphite.

The specific gravity is 2.52.

In 1881 Colson and Schntzenberger described before the Paris Academie des Sciences, a green coloured powder having the formula SiCO , which they prepared by passing a stream of carbon dioxide over silicon which was slightly heated in a porcelain tube. This was the first silicon-carbon-oxygen compound of its kind.

Acheson, in 1903, patented a process for the manufacture of a highly refractory substance of a composition varying between $\text{Si}_2\text{C}_2\text{O}$ and $\text{Si}_2\text{C}_3\text{O}$. It has been described more than once; and Mr. Bertram Blot reported in the "Analyst" for February of this year that he had estimated directly the total carbon in siloxicon by heating it with lead chromate, the silica directly, and oxygen by difference. No figures were given and I have found anywhere an account of a detailed analysis of the substance. I have attempted such an analysis in the following manner.

The percentage of total silicon was determined by fusion with sodium peroxide in a nickel crucible. Vigorous action occurred, and the resulting silicate was decomposed with hydrochloric acid, and the silica estimated in the usual way, after separation of the iron and of some of the derived from the crucible.

* Taken as read.

* The authors' thanks are due to Miss F. M. G. Micklethwait for assistance in preparing the tetrahydronaphthalene derivatives employed in this investigation.

the total carbon was estimated as follows:—A sample fused in an iron boat in a combustion tube with an excess of sodium peroxide. Potash absorption was fitted to one end to retain any carbon dioxide which might escape the peroxide; as a matter of fact, it did escape. To the opposite end was attached an open bottle to remedy any back pressure caused by a local action within the tube, and to wash out the gases at the end of the reaction. The ordinary carbon dioxide was performed on the fused mass, and the gas was dissolved into a mixture of calcium chloride and ammonia, was boiled, and the calcium carbonate precipitated, filtered, and weighed as lime. It was found that dilute uric acid acts well in liberating the carbon dioxide, chlorine is evolved if hydrochloric acid is employed, owing to its action on the sodium peroxide.

In the above-mentioned estimation of carbon, none of the gas escaped combination with the sodium peroxide, an analysis, sufficiently accurate for all purposes, can be effected by tipping small quantities of a mixture of siloxicon with an excess of sodium into some peroxide fused in a nickel crucible; sodium carbonate and sodium are formed, and each can be estimated in the way already indicated.

A portion of the siloxicon was heated in chlorine, some silicon was volatilised as tetrachloride together with ferric chloride and a very small amount of aluminium chloride. The vapours were collected, as already explained, passing them over the surface of water and then through cotton wool. The separation and estimation of the iron, and aluminium were carried out in the usual way. The weight of silicon, iron, and aluminium collected was less than the loss of weight of the siloxicon, but this was due up by the presence of a substance having the formula SiC_2O_3 , which will be accounted for later.

The residue was then heated in oxygen and the carbon dioxide formed was estimated as before. The residue was $\text{Si}_2\text{C}_2\text{O}$.

Another portion was heated to determine the moisture. A third portion was boiled for some time with hydrofluoric acid; the filtrate was found to contain ammonium monosilico fluoride; this proves the presence of silicon nitride; the amount was, however, too small to be estimated.

The results of these estimations are as follows:—

fusion with sodium peroxide:		
Total Si	50.31	per cent.
fusion with sodium peroxide:		
Total C	31.39	"
heating in chlorine:		
Si	7.54	"
Fe	1.07	"
Al	trace.	
heating in oxygen:		
C	11.79	"
heat:		
Moisture	0.19	"
treatment with hydrofluoric:		
N	trace.	
residue in the boat:		
$\text{Si}_2\text{C}_2\text{O}$	71.39	"
these give:		
Total Si	50.31	"
Total C	31.39	"
Fe	1.07	"
Moisture	0.19	"
Al_2O_3 and N	traces.	
O (by diff.)	17.04	"
	100.00	"

At the residue left in the boat was $\text{Si}_2\text{C}_2\text{O}$ was substituted by a further quantity being prepared and analysed, as well as by the close agreement with the Si calculated for $\text{Si}_2\text{C}_2\text{O}$, and the difference between the amount of total silicon and that volatilised in chlorine.

The carbon burned off in oxygen occurred in the siloxicon as carborundum (which was decomposed by HCl) and partly as graphite. This quantity with the amount calculated to be in the $\text{Si}_2\text{C}_2\text{O}$ subtracted from

the total carbon found by the peroxide fusion left 1.47 per cent.

The amount of oxygen in $\text{Si}_2\text{C}_2\text{O}$ subtracted from the total oxygen left 5.24 per cent. Thus, with the 1.47 per cent. of carbon just mentioned, is almost exactly that required for 10.81 per cent. of SiC_2O_3 , which contains 3.48 per cent. of silicon. This amount of silicon subtracted from the amount volatilised in chlorine gives the amount of silicon present as carborundum, *i.e.*, 4.08 per cent. The amount of carbon thus combined equals 1.73 per cent., which, if subtracted from the weight of carbon burned off in oxygen, leaves the amount of carbon present as graphite.

Thus, commercial siloxicon is resolved into:—

$\text{Si}_2\text{C}_2\text{O}$	71.39	per cent.
SiC_2O_3	10.81	"
SiC	5.81	"
Graphite	10.06	"
Fe	1.07	"
Volatile matter	0.19	"
Al_2O_3 , Si_3N_4 (by diff.)	0.67	"
	100.00	"

Considering that siloxicon is obtained as a by-product from the carborundum furnace, it is to be expected that some free silicon will be present. This accounts for the silicon nitride being found in the substance as it would be formed by the action of atmospheric nitrogen in the furnace; the atmospheric oxygen together with free carbon may well be responsible for the SiC_2O_3 . The actual existence of this substance in siloxicon is open to question, since, although it fits in well by calculation, it should not, according to Dammer's *Anorganischen Chemie*, be decomposed by chlorine.

In the course of the search for a method of analysis the following properties and reactions were observed:—

Fusion mixture and fused potassium nitrate acted vigorously but not completely.

Hydrofluoric acid and sulphuric acid caused slight decomposition. Fused ammonium fluoride was without action.

Heated lead peroxide acted vigorously, but attacked also the containing crucible.

Concentrated potassium permanganate solution was allowed to act on some siloxicon for a week on a water-bath. Colourless soluble and insoluble compounds, as well as some tarry matter, were formed; and instead of getting rid of the free carbon quantitatively, there was an increase of weight amounting to about 14 per cent.

Manchester Section.

Meeting held at Manchester, on Friday,
May 5th, 1905.

MR. J. CARTER BELL IN THE CHAIR.

THE RECOVERY OF PRODUCTS OF COMMERCIAL VALUE FROM SEWAGE SLUDGE.

BY J. GROSSMANN, PH.D., F.I.C.

In the year 1898 (this J., 17, 421—424) I read a paper before this section dealing with the problem of obtaining products of value from sewage sludge by distillation at such a temperature as to produce gas suitable for technical purposes, and to drive off ammonia, whilst leaving a residue which should be available for use as a manure. I was fully aware at the time that there were serious objections to such a scheme. One, which is always a great and in many cases a fatal one was that it had been tried before and found impracticable. It could also be urged that the gas produced could only in very rare cases be utilised on the sewage works, and would, therefore, have no value, and in the discussion which followed my paper it

was maintained that the residue from the distillation would be worthless. The principles which I wished to establish were that the mechanical difficulties which had in the past been in the way of solving the problem could, in the present advanced state of engineering, be overcome and that it might pay to use precipitants more or less in excess, and produce more sludge so long as the products obtained more than covered the expenses of working.

Since that time I have had ample opportunity of proving the correctness of my ideas on the construction of furnaces, on distillation, and on other matters relating to chemical engineering on a large scale in connection with other processes, and the Corporation of Bradford consulted me, towards the end of 1903, on the feasibility of subjecting their sewage sludge to distillation, and subsequently requested me to prepare the necessary plans and specifications for an installation dealing with 16 tons of sludge per day, *viz.*, one-third to one-fourth of their total production.

It is well known that Bradford is the centre of the woollen industry in Yorkshire, and that from industrial processes incidental to that source its sewage is exceptionally rich in fatty matter. It was found that by adding a small quantity of sulphuric acid to the sewage, insoluble matter settled out well, and that the sludge thus obtained held the greater part of the fatty matter originally contained in the sewage. It was also found that if this sludge, which is charged with about 80 per cent. of water, was heated with a suitable quantity of sulphuric acid, and whilst hot passed through a filter press, a considerable quantity of grease could be removed from the liquor running from the presses. But it was found impossible to thus recover all fatty matter and I was informed that the sludge cake coming from the filter presses contained 24 per cent. of grease, equal to about 40 per cent. of matter, which could be extracted by ether, after the cake had been dried at 100° C. I have subsequently found that, according to the state of the woollen trade, which fluctuates with the seasons and to numerous other contingencies, the amount of fat in the sewage cake varies considerably, and may be as low as 7 per cent. and even less.

Apart from the question of expense, the sludge thus obtained became a serious nuisance, and various processes of recovering the fat in it by extraction with volatile solvents, and at the same time obtaining a residue which should be innocuous, and of some value as manure, were tried on a large scale, but without success. Experiments carried on by the Bradford Corporation at the Frizinghall Sewage Works, in which the sludge cake was heated in a large pot-shaped still, particularly in the presence of superheated steam, and under a vacuum, gave more encouraging results, and although it was found impracticable in the experimental plant to determine the best conditions under which the distillation could be carried out, and although a large amount of the fat was decomposed and lost in the form of hydrocarbons, yet the fact was established that it was possible to distil over a certain amount of fat and to obtain a dry residue containing only a small quantity of fat and sufficient nitrogenous matter to be of manurial value.

With these data, and a sample of sludge cake to go upon, it occurred to me that the principal conditions under which a plant should be constructed, were as follows:—

1. That the sludge should be heated in comparatively thin layers. A simple mathematical calculation shows that in the case of bad conductors the heat as transmitted from the outside to the centre of the cake will decrease in a geometrical progression, whilst the thickness of the cake is made to increase in an arithmetical progression, so that a comparatively slight alteration in the thickness of the sludge cake will make a considerable difference in the results.

2. That the furnaces should be capable of maintaining an even heat at temperatures varying from 200° to 500° C., or even more.

3. That manual labour should be dispensed with as far as possible by the substitution of mechanical appliances by which the process could be made continuous, and almost automatic.

4. That under these circumstances it would be practicable to maintain a high vacuum, but that minus pressure in conjunction with superheated steam would be most likely to give satisfactory results.

Generally speaking, it could be assumed that the efficiency of the apparatus would be a function of three variables, *viz.*, the temperature, the thickness of the cake, the time of the operation, *i.e.*, in a continuous apparatus the speed with which the mass was moved from one retort to the next. As these were unknown quantities, parts of the apparatus had to be constructed with a view to subsequent adjustment and alteration. Particular attention had to be made, moreover, to prevent access of air to the system during charging and discharging, and to guard against explosions if hydrocarbons should be evolved in sufficiently large quantities.

It is on these lines that the plant which I have now constructed, and it consists briefly of the following arrangements.

The distillation takes place in eight D-shaped retorts which are placed side by side at convenient distances in a furnace bed in such a manner that the space between the fourth and fifth retort is greater than that between the others to allow for the exit flue to pass between them. This arrangement really represents two sets of four retorts built back to back. The fire gases run in flues at angles to the length of the retorts under and above them in such a manner that the whole system is similar to a regenerating furnace or baker's oven, where the heat is mostly given off by reflection from the heated bricks or tiles, and are finally taken through the chimney referred to before into the main flue and chimney. In that way it is possible to maintain an even temperature and yet vary the heat from 200° to 900° C. The retorts are heated separately and independently from each other, so that more heat may be used on certain portions of the retorts than on others. This is an important feature in the construction as the process of distillation consists of two separate parts, firstly the expulsion of the water from the cake and, secondly, the distillation of the fat. More or less, both processes take place simultaneously at the beginning of the operation, still the chief quantity of heat will be required for the evaporation of part of the water which takes place first, and, therefore, a greater amount of fuel will be necessary in that part of the furnaces nearest to the charging apparatus. The retorts are closed at both ends, and a scraper arrangement travels very slowly on the flat base of the D-shaped retorts, the bottom of the retorts, in such a manner that the sludge, which is fed in at the top, is slowly moved along at a proper rate, and is practically free from fatty matter when it is discharged at the other end. Perforated pipes are fitted inside the retorts for the supply of superheated steam. The feeding is arranged in such a manner that two closed hoppers, one above the other, are connected with an opening at one end of the retorts; the top hopper is being charged, the bottom one is discharging into it by means of a funnel plug, so that no air enters the retorts during the feeding from that part. The discharging part is arranged in a similar manner in emptying the discharging box it is disconnected from the retorts. This is effected by feeding the dry residue from the retorts alternately into two different boxes, each of which is disconnected from the rest of the retorts whilst it is being opened and emptied, thus preventing access of air to the retorts. An arrangement for the waste material is interposed between the retorts and the discharging tanks, and acts at the same time as a safeguard against explosions. The gases leave the retorts at the top nearest to the end from which the waste material is discharged; they are taken through suitable coils and scrubbers in which the fatty acids are condensed, and other organic compounds and ammonia are separated, and finally pass through an exhauster into the chimney. There is no nauseating smell arising during the course of distillation.

The cost of the installation is about £4,000; the fuel burnt per 24 hours amounts to two tons of coke, and the labour at 6d. per hour to 36s.; so that depreciation and interest into account, the total cost comes to £4 per day for the distillation of 16 tons of sewage sludge.

containing from 40 to 50 per cent. of water. As installations could be erected at less expense, and as economies could be effected in labour and fuel, it may be taken as the maximum cost of production. The products obtained per 24 hours are 7 tons of residue, containing besides free carbon about 2 per cent. of nitrogen, and 8 per cent. of ammonia sulphate and 1 per cent. of phosphoric acid, equal to a little over 2 per cent. of calcium phosphate, and a quantity of grease which is on the original quantity contained in the sludge. It is, however, from these two products, I have found, as anticipated in my paper of 1898, that other valuable compounds are produced in the process of distillation. So far, I have been able to determine and to separate butyric and similar acids, and there is evidence in the manurial bases and other compounds in the distillate. The total of organic acids obtained when working at a higher temperature than necessary to obtain the best results as far as the yield of grease is concerned, is about 24 hours to 50 lb., of which 25 lb. was butyric. These acids can be easily recovered, and should be a considerable source of revenue. In the case of a sludge containing small quantities only of fat, it might be advantageous to regulate the distillation with a view to maximum production.

The total amount of nitrogen recovered, including that contained in the manurial residue, and calculated as ammonia is a little over 1 per cent.; that of phosphoric acid is about $\frac{1}{2}$ per cent. reckoned on wet sludge. Possibly the yield of these products might be obtained by using the residue, or in conjunction with acid, a suitable product in the preliminary treatment of the sewage. Economy might also be effected in the final boiling of the sludge by the use of sulphuric acid to which the sludge is subjected; the process part of the phosphates which have settled in the sludge will become decomposed; the liberated phosphoric acid will run to waste with the effluent from the presses, and probably carry with it some colloidal matter and other nitrogenous compounds. By pressing the effluent from the presses it should be therewith possible to recover a further amount of valuable products. The use of phosphoric acid or acid phosphates in either of these operations may some day be advantageous.

As I have stated before that, under normal conditions, the sludge as it comes from the filter presses should contain about 24 per cent. of grease, and with such sludge, even for all possible losses, the amount of grease recovered should pay all working expenses and show a profit. But as there are only few towns which could produce sludge rich in fatty matter, the results obtained in Bradford would, under ordinary circumstances, be of general interest. It was a fortunate accident, however, that the sludge placed at my disposal was from a storm-water tank, and contained only 7 per cent. of fat, a percentage which is abnormal for Bradford. The sludge resembles normal sludge as obtained from ordinary domestic sewage. It was found that even with such a low percentage of fat the manurial residue and the grease recovered products recovered will pay the working expenses. I am thus enabled to consider the question of the results which I have obtained in Bradford as influencing the general treatment of sewage in other towns.

Up to the present, the sludge produced at sewage works has, in most cases, been a source of nuisance and expense. Loaded with a large amount of water it has been to be removed, and the aim has therefore been to reduce the quantity produced to a minimum. For this reason even where chemicals were used for precipitation, they were brought down to the smallest quantity, just enough to produce an effluent which could afterwards be purified by filtration, with the result that the valuable elements contained in the colloidal matter were wasted. It is, therefore, that for every tenth of a per cent. of ammonia recovered in the sludge a further gain of 10d. per ton can be realised, it is possible that where chemicals are used to present an increase in their quantity might be more than compensated for by the additional yield of ammonia and phosphoric acid. In whichever way produced the sludge will require treatment with sulphuric

hydrochloric or phosphoric acid, and filter press, and any valuable ingredients in the press effluents could be recovered as previously indicated. The temperature at which the sludge cake should be distilled will vary in different localities; it will be ascertained by conducting the operation at gradually rising temperatures, and noting the quantity, nature, and value of the products obtained, and accepting that temperature as most suitable at which the total value of the products is highest.

There are certain ingredients in sewage which are removed from it partly by dredging, partly by means of screens, and which up to the present have been dealt with separately. It may be found that in some cases it will be advisable to mix these matters after suitable mechanical treatment, that is, disintegration or otherwise, with the sludge; and possibly part of the refuse obtained from ashbins, and dealt with at present in the destructors, might be utilised in the same way. The question which will in each case have to be determined, will depend upon the fact under what conditions the manure and the products of distillations obtained will produce the best commercial results. In many cases it may be possible to enrich the sludge by conducting the settling on a system of differentiation, with the object of obtaining a sludge in the first tanks which contains more fatty and nitrogenous matter than the average sludge which would be obtained by settling without differentiation.

It may be possible by judicious manipulation to greatly enhance the value of the products obtained; that of the residue by mixing it with materials which would improve its manurial value; that of the grease by refining; and that of the organic acids by converting them into fruit essences, or other more complex compounds. But this is a matter which, as it affects the principle of municipal trading, will have to be settled by the respective authorities who control the disposal of sewage. In my calculations, I have only dealt with the products as they leave the apparatus.

DISCUSSION.

The CHAIRMAN said, considering that Dr. Grossmann had worked upon a sludge containing 5 or 6 per cent. of fat, it was marvellous how it could be made to pay expenses. If the Salford Corporation could make something out of the 200,000 tons of sludge which contained about 40 per cent. of total solid matter, it would be a very great advantage.

Dr. C. DREYFUS thought the first question was—Why should they wish to extract the grease from the sewage? The reason why grease was so objectionable in the treatment of sewage by biological methods was the fact that if it were allowed to get on to the bacteria beds it clogged up the pores of the beds, and prevented to a certain extent the sewage from penetrating and becoming purified. This was one of the great difficulties, and it was, therefore, quite a problem for chemists to get rid of the grease. It had been done on a large scale in several places. In Germany they treated the sludge which they obtained by sedimentation in suitable tanks, by adding a sufficient quantity of sulphuric acid to decompose the lime and other fatty soaps which were formed in the process, by which means and subsequent pressing they were able to concentrate the sludge itself, which previously contained about 10 per cent. of solids, to one of 30—40 per cent. of solids. This was afterwards dried in a suitable apparatus until it contained about 10 per cent. of moisture, when it was treated by petroleum spirit or benzole. By this method they obtained very good grease, but he hardly thought it had been a commercial success. He thought the extraction of grease from sewage could not be made to pay, and it would be quite sufficient if the process could be carried on without entailing serious expenditure. In Bradford they had, at one time, an excellent plant for the purpose; they started with the idea of treating the wet sludge with a solvent, and by an ingenious method they succeeded in extracting almost all the fats contained in the sludge, but the loss of solvents must have been very considerable. He hoped the process described by Dr. Grossmann might be successful. What quantity of sulphuric acid did he use for every million

gallons of sewage? What was the yield obtained out of the sludge which contained 7 per cent. of total fats? How much of that fat was left in the residue after treatment? The treatment of large quantities of sludge would necessitate the fitting up of most expensive and elaborate plant. Dr. Grossmann had said that for treating only 16 tons of sludge he had to spend something like about £4000. Sixteen tons of filtered press sludge was a very small quantity indeed for a large population like Manchester. Even if it could be shown that there was no loss in the working, Manchester was better situated as an inland town, owing to the Ship Canal, and by reason of their being able to send the sludge out to sea by steamer. The cost, although a very heavy one, did not reach a very large figure. The cost of disposal of sludge in inland towns was becoming daily a more difficult problem. The most valuable method would be one whereby the fatty matters could be extracted before they passed into the sludge, and so obtain an effluent free from those elements so injurious to the bacteria beds. It was on these lines both inventors and chemists ought to work.

Dr. G. J. FOWLER said that he was not quite clear as to the percentage of fat in the sludge with which Dr. Grossmann had worked. If the material represented normal Bradford sludge it would be of such a nature as would hardly be met with in any other town except Bradford, which had an industry producing large quantities of fat. The average percentage of fat on the dry material in most towns would range from 15 to 20 rather than 40 per cent.; therefore, they would have at once a very considerable difference on which to calculate the cost. At the same time he would like to emphasise his opinion that a town was not necessarily concerned in making the extraction of grease a financial success in itself as apart from reducing the cost of sludge disposal, and it was on those lines that the economies of the subject should be looked at. He agreed with Dr. Dreyfus entirely that the ultimate solution of the problem would probably be arrived at by a combination of experience of various kinds.

Dr. G. H. BAILEY said he understood Dr. Grossmann in his paper was dealing with 5 per cent. of grease from storm-water tanks, and not, as Dr. Fowler had evidently inferred, with 25 per cent. This was one of the most essential points of the paper since the remarks became applicable to all forms of sewage. Assuming that there was something like 200,000 tons of soap used per annum, the recovery of a small percentage of the fat would be some advantage. Could this process be applied generally to sewage and would it be possible to construct an experimental plant on a small scale that could be used for the investigation of the sludge from a small population? Dr. Fowler and Dr. Dreyfus had both emphasised the importance of removing the fat and colloidal matters from the sewage before passing it on to the bacteria beds. If this were done the separation would yield an addition to the sludge, as it was inconceivable that any method dealing directly with such large volumes of liquid should effectually destroy the grease. At the previous meeting Dr. Fowler had spoken hopefully of the precipitation of the colloidal matters, and if this were done, even partially, the sludge would become enriched with bodies rich in nitrogen and the value of the process before them would be enhanced.

Dr. K. E. MARKEL supplemented Dr. Bailey's remarks by intimating that the total production of soap in Great Britain was over and not under 400,000 tons per annum. He asked for information with regard to the composition of the recovered sewage fat, especially relating to the proportion of "glycerides" and wool fat or "cholesterine"? He considered this important, because the composition in this respect determined its market value, and, further, because it would indicate whether the sewage yielding this fat was of an exceptional nature. Bradford sewage presented the same difficulty of treatment as other districts where the woollen industry was rife. Such sewage always contained cholesterol in appreciable quantity—a substance, which, owing to its inert character, combined with extraordinary emulsifying power, was probably the most objectionable constituent in sewage. His own

experience with regard to precipitation of ap- chemically inert organic substances led him to believe they were far from understanding even the elementary principles underlying sewage precipitation in all its details. Why did calcium carbonate for example precipitate all the organic substances precipitated by lime? In practice 1.25 tons of calcium carbonate precipitated the same weight as did 1 ton of unslaked "Absorption," a term lately introduced to indicate chemical precipitation of neutral bodies by neutralisation, may be convenient, but was by no means satisfactory. In certain sewage works calcium oxide had been treated with success by calcium carbonate containing 10 per cent. calcium hydrate. This raw material only cheaper, but its application required less and less plant, produced a denser precipitate, a was more important, produced a non-alkaline, and less putrescent effluent.

Mr. F. SCRUPPER asked Dr. GROSSMANN to state the capital cost of a plant to deal with a definite volume of sewage sludge expressed as money required per ton of sludge treated, and also to state the weight and the bye-products recovered. The whole question simply one of expense, and without this information value or otherwise of the process could not be determined. Before Bradford obtained their Act of Parliament to compel the woolcombers to treat their trade effluent prior to entering the sewers, something like 45 tons of grease passed per day into the town's sewage, subsequently reduced to about 28 tons. Bradford produced about 220 tons of sludge with 50 per cent. grease per day. There was a desire on the part of the town to adopt a recovery process for this grease. Dr. Dreyfus had remarked, the Dellatre process tried amongst others, and in spite of the fact that the Chief Engineer of the Department du Nord had issued a statement showing that a profit of 81s. a day made out of the Roubaix and Tourcoing sewage, with the Dellatre process at Frizinghall had not been so successful as was anticipated. With regard to Dr. Grossmann's scheme there was further the question of wear and tear of the retort settings and renewals considered, and, having regard to the fact that the retorts had no commercial value, it was in fact to know the yields of ammonia, acetic acid, and other products which he proposed to recover. It was not a question of quantity of the nitrogen and phosphoric acid, but of the "available" nitrogen and the "available" phosphoric acid.

Dr. GROSSMANN, in reply, said that, although with him he was called in to work on the Bradford sewage through an accident, he was supplied with a sample tank which was not strictly typical of Bradford sludge, which was of the nature of sludge obtained from domestic sewage. He did not say that his process could be applied to every town, but no doubt there were localities where it might, with advantage, be applied. He also did not say that the preliminary treatment of the sewage would make the effluent what it should be. In some cases, by the preliminary treatment, the sludge might be produced which would pay even at a percentage for working up. So far as he could see at the lowest limit of fat at which it will pay for wool, it would be from 5 to 7 per cent. on the wet cake. Farmers were paying 2s. 6d. per ton for the residue from the tanks, and as much as 3s. 6d. for the cake offered. It had been valued by an authority at about 5s. A weak sludge would yield 100 lb. of grease per day, and this, together with the residue, would produce more than £4 per day. This brought to a figure at which there would be a reasonable profit, even with a small amount of fat. As already shown—and in which Dr. Fowler could not differ—the differentiation in the settling tanks could be used for this purpose, and the fact that it was not that an apparatus could be made for using it might induce others to give their attention to the sewage treatment which hitherto have had no attention. Dr. Dreyfus was quite right in saying that farmers would not use any manure that

a large amount of fat, but if it could be reduced to from 2 to 3 per cent. in the residue, and from 1 to 1½ per cent. calculated on the fat in the original cake, it would do no harm. Dr. Dreyfus had also stated that it would be of great expense for Manchester to deal with the sludge in the manner suggested in the paper. He (Schmied) did not think it necessary that Manchester should utilise the whole of the sludge. He wished to see the fact, which did not appear clear to Dr. Fowler, that the sludge at his disposal was not typical sludge, but only contained from 5 to 7 per cent. of the wet, and that, with a system of differentiation, he could produce sludge much richer in fat than he happened to deal with in Bradford. With reference to Dr. Dreyfus' remarks relating to the prevention of fat or soapy matter passing into the effluent, it was his opinion that after all there were only three ways in which this could be done, viz.:—(1) by dissolving the fat by means of a solvent, which would not be a practically practicable process; (2) by bacterial methods, which would mean that the valuable constituents would be destroyed and lost; (3) by precipitation, which would yield the fat in such a form that it would have to be treated by such a process, as suggested in the paper. Dr. Fowler asked where the butyric acid came from, this was a difficult question to answer, but from his remarks he was inclined to think that it was not a product of decomposition of fat, but that it came from the stearic acid in the sludge. In reply to Dr. Bailey, he said that it would be possible to construct an apparatus suitable for small localities. An eighth of the cost of the plant could be applied for experimental purposes or for large works at a comparatively low cost, and the plant could be reconstructed and again form part of the regular installation. It would be quite possible to have an installation consisting of one retort, and to have a small condensing plant. Replying to Dr. Bailey's remarks as to the quantity of cholesterol and glycerides, the speaker said that the work which had been made so far, had been confined to the chemical valuation of the grease recovered in connection with the further purification by distillation, and therefore its saponification value had been determined. He said that his statement with regard to the quantity of sludge in Bradford must have been based on a misunderstanding. The quantity obtained there was 20 tons per day, but from 50 to 60 tons.

the coast of Asia may be seen distinctly across Behring Strait, while to the right lies the Arctic Ocean, and to the left the Behring Sea. The climate is severe, but not so bad as it is supposed to be by those who have not been in the Arctic regions. The summers are moderate, and though the winters are stormy and cold, it is only for two or three months that very bad weather lasts, and then one is prepared for it. The country is completely cut off from supplies from the outside world from November to June, both inclusive, so that all necessities must be brought in during the open months. During these open months the ocean is clear of ice, and steamers run between Nome and Seattle, and Nome and San Francisco.

Wm. C. J. Bartels, of the Bartels Tin Mining Co., was the first to find tin, in 1901, on Cape Mountain and in the vicinity. Since that time numerous strikes have been made at other places from 10 to 30 miles distant. Indeed, it would seem that the whole neighbourhood abounds in tin ore, cassiterite, mixed with granite of various kinds, the cassiterite being sometimes in large crystals and at other times intimately mixed with the granite.

Assay of Tin Ore.

The cyanide assay is the best both for speed and accuracy. This assay depends on three properties of the cassiterite—one physical, the other two chemical: its high specific gravity, seven; its insolubility in aqua regia; and its quick and complete reduction by fusing with potassium cyanide, the equation for the reaction being $\text{SnO}_2 + 2\text{KCN} = 2\text{KCN} + \text{Sn}$.

The sample is ground through a 60 or 80 mesh sieve and thoroughly mixed. From 25 to 100 grms. are then concentrated by panning down with water to remove the lighter substances. The concentrates will now consist of cassiterite, mixed with any heavy minerals which may have been contained in the ore, and which in our ores are usually small quantities of iron oxides, with occasionally some wolframite. The concentrates are now boiled with aqua regia for half an hour. This dissolves the iron, changes any tungsten compounds to insoluble yellow tungstic acid, and leaves the cassiterite unattacked. The concentrates are now washed by decantation, and any tungstic acid removed by solution in ammonia. They are then washed again, dried and weighed. If only an approximate assay is needed, which is often the case, the tin may be estimated by calculation, the concentrates from our ore always containing very close to 70 per cent. tin. If more accurate work is desired, the dried concentrates are mixed with about five times their weight of powdered potassium cyanide, and melted in a clay crucible at a good red heat. The tin is reduced and collects in a button at the bottom of the crucible.

Analyses of buttons obtained in this manner have shown them to be practically pure tin, the impurities in a one grm. sample being too small to be collected and identified.

Meeting held at the Chemists' Club, on
Friday, May 19th, 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

TIN IN ALASKA.

BY MARTIN SCHWITTER.

The discovery of tin on the Seward Peninsula, Alaska, has interested to a region already important since the discovery of rich placer goldfields at Nome, in 1899. The Seward Peninsula is the most westerly portion of the American Continent, and it is within 30 miles of the most westerly point, Cape Prince of Wales, that the most important discoveries have been made. The country, which is practically unknown, is composed of timber and consists of mountains of from 2,000 to 3,000 ft. high, which rise abruptly from the ocean. Cape Mountain is about 3,000 ft. high, and its apex is probably not half a mile from the shore line. From this mountain on a clear day,

THE EFFECT OF ALKALINE SCOURING AGENTS ON THE STRENGTH OF WOOLLEN YARNS.

BY J. MERRITT MATTHEWS, PH.D.

The experimental work on which this paper is based was undertaken with the view of ascertaining as far as possible the effect of soap and alkaline solutions on the tensile strength, elasticity, lustre, degree of cleansing, &c., of woollen yarns. The yarn I employed was of a medium grade, all woollen yarn, carded and spun with an emulsion containing lard oil and borax; it had been spun about six months. In its unscoured condition it was of a greyish colour, like all yarn of this class, and contained a small amount of iron (about 0.1 per cent.). The amount of grease and miscellaneous dirt was 6 per cent. This figure was determined by extraction of a sample with petroleum ether and then scouring in soap. Nearly all yarn of this character will contain varying

amounts of iron mixed in with the oil and dirt in the fibre. This is derived from the wearing of the metallic parts of the cards and spinning frames through which the wool passes in the course of its manufacture, and I doubt if it is possible to spin this class of yarn without it showing at least a trace of iron. In my tests I employed small skeins weighing about 5 grms., and containing 23 strands. The various scouring tests were made in porcelain beakers with 250 c.c. of the respective solutions, and the small skeins were systematically worked in these solutions as in the usual method of scouring by hand. After scouring the samples in this manner for 20 minutes, they were washed well in fresh warm water, squeezed, and dried. The amount of loss in weight of each skein was determined, and tests were made to determine the tensile strength and elasticity in each case.

First, the effect of hot water alone was determined. The tensile strength of the unscoured yarn was 28.5 lb. to the skein of 23 strands (this determination was a mean of three sets of tests on five different skeins—minimum 28 lb., maximum 30 lb.). The elasticity was 19 per cent., and was determined in the same manner. On treatment with plain water at a temperature of 140° F., the yarn lost 2.2 per cent. in weight, and decreased in strength 37 per cent. to 17.8 lb. (a mean of three tests, as are all the figures to be given). The elasticity appeared to be unaltered. When treated with boiling water, the yarn lost 3.4 per cent. in weight, and suffered about the same diminution in strength. Both samples showed that a considerable amount of the grease and dirt had been removed by emulsification, although they were by no means in a scoured condition, and they still exhibited the presence of iron, though to a much less degree than in the original.

The results of this set of tests are tabulated as follows:—

TABLE I.—Effect of Hot Water.

No. Exp.	Temp. F.	Strength.		Elasticity.		Loss in Weight per cent.	Remarks.
		Lb.	Loss in %.	Per cent.	Loss in %.		
1	original	28.5	—	19.0	—	—	contains iron
2	140	17.8	37.0	19.0	0	2.2	do.
3	212	18.2	36.0	19.0	0	3.4	do.

The effect of soap solutions was next taken up. The soap employed was a neutral olive oil soda soap free from resin. Using a solution containing 5 grms. of soap per litre, skeins of the woollen yarn were scoured at different temperatures. Scouring at 65° F., the loss in strength was about 5 per cent. more than with boiling water alone, although the elasticity was not affected. It will be noticed from the table (II.) that increasing the temperature of the soap scouring bath from 65° to 212° F. causes a gradual decrease in the tensile strength of the yarn, though the elasticity is not altered until we reach 140° F., and even up to the boil the elasticity is not very greatly affected. Complete scouring, however, is not obtained until the temperature of 140° F. is reached, and from that point to the boil the amount of matter removed from the yarn is practically the same, so it may be said that the cleansing of the yarn is as complete at 140° F. as at the higher temperatures. Both the tensile strength and elasticity, however, run down considerably beyond 140° F. An important point to be noted, in connection with these tests on soap scouring, is that the wool scoured by this means appeared to have all of the iron removed from the fibre; only in the skein scoured at 65° F. was there a trace of iron still found, whereas all the other tests showed the complete absence of iron. Herein the scouring with soap differs from the scouring with all other alkalis, for it will be shown in the succeeding tests that the iron was not removed from the fibre, but was fixed therein as an insoluble oxide, a condition which we would naturally expect in the use of alkali carbonates and hydroxides.

TABLE II.—Effect of Soap Solutions.

(5 grms. per litre).

No. Exp.	Temp. F.	Strength.		Elasticity.		Loss in Weight per cent.	Remarks.
		Lb.	Loss in %.	Per cent.	Loss in %.		
4	65	16.8	41.0	19.0	0.0	4.2	trace of iron
5	100	15.3	46.0	19.0	0.0	4.5	no iron
6	140	12.6	55.0	18.0	5.0	5.7	do.
7	180	11.4	60.0	17.0	10.0	5.6	do.
8	212	10.8	62.0	16.0	15.0	5.9	do.

The action of solutions of soda ash was next studied. In these tests two series were made; in the first (III.), the temperature of the scouring solution maintained constant at 140° F., while in the second the strength of the alkali was maintained constant at 5 grms. per litre, and the temperature was varied. In all cases of the use of soda ash the yarns were perfectly scoured, and there was iron to a greater extent always left in the fibre, giving it a brown colour. The lustre of the fibre was considerably altered, especially in the stronger solutions of soda ash, at the higher temperatures. At points where sufficient alkali was employed and at a high enough temperature to remove all of the oil from the yarn, the fibre was in a lifeless condition without the resilience to be found in yarn scoured with soap alone. On reference to the tabulated results, a peculiarity will be observed, the effect of soda ash solutions of different strengths is, the tensile strength apparently increases with increase in the strength of the alkali. This, however, is accounted for by the fact that the stronger alkaline solutions cause the fibres of the yarn to shrink together considerably, and a good deal of felting also results, which produces a greater coherence among individual elements of the yarn. In order to remove all the grease from the yarn at a temperature of 140° F., it requires a scouring solution containing at least 15 grms. of soda ash per litre.

TABLE III.—Effect of Soda Ash Solutions.

(at 140° F.).

No. Exp.	Grms. per litre.	Strength.		Elasticity.		Loss in Weight per cent.	Remarks.
		Lb.	Loss in %.	Per cent.	Loss in %.		
9	1	12.5	56.0	19.0	0.0	4.0	contains iron
10	2	13.6	53.0	19.0	0.0	4.3	do.
11	3	15.8	45.0	19.0	0.0	4.4	do.
12	5	14.1	50.0	19.0	0.0	4.8	do.
13	10	17.4	39.0	18.0	5.0	5.3	do.
14	15	18.0	37.0	17.0	10.0	5.6	do.

Scouring with solutions of soda ash at temperatures higher than 140° F. is attended with great deterioration in the quality of the yarn even with a strength of only 5 grms. of soda ash per litre. At a boiling temperature the yarn is practically destroyed as far as any utility is concerned.

TABLE IV.—Effect of Soda Ash Solutions.

(5 grms. per litre).

17	212	11.6	59.0	11.0	44.0	6.0	do.

destructive action of caustic soda on wool is a
own fact, and yet most of the common soaps
pl for the scouring of wool and woollen materials
more or less free caustic alkali. In the set of
ents with respect to the effect of caustic soda
V.), it will be found that the destructive action
alkali starts at a strength of 0.1 gram. per litre at
rature of 140° F. This strength of alkali, however,
t effect a scouring of the yarn to any better extent
ain water at the same temperature, whereas the
nce and feel of the fibre is very evidently de-
ed. In none of the experiments with caustic
s the scouring complete, even so far as the removal
grease alone was concerned; and in every test
present in the unscoured yarn was fixed in the
At a strength of 0.5 gram. of caustic soda per litre,
temperature of 140° F., the skein of yarn suffered
h that it would be useless for manufacturing
s; it still, however, possesses considerable strength
o the great felting together of the fibre; it will
ed, however, that the elasticity of the fibre has
a low figure. The loss in weight also shows me
of the fibre has been dissolved, and the
nce of the yarn showed that structural disintegra-
the fibre had proceeded to a considerable degree.

ing with solutions of ammonia does not appear
ld the results in practice which are usually
for this scouring agent in text-books. In Table
shown the results obtained by scouring with
a solutions of different concentrations at the usual
temperature of 140° F. It will be seen that a
e removal of grease and oil is not effected until a
of 10 grms. of ammonia per litre is reached. The
ation of the grease and dirt does not appear to be
s perfect with ammonia as with plain soap solu-
ad the ammonia also fixes the iron compounds in
and leaves the wool of a brownish tint instead of
ost pure white which results from scouring with
Ammonia, however, does not appear to affect the
of the yarn to any appreciable extent unless
temperatures are employed, as may be seen in
III.

TABLE VII.—Effect of Ammonia Solutions (at 140° F.).

Experiments with the use of borax proved this alkali to
be a very unsatisfactory scouring compound in this con-
nection. Its power of emulsification does not appear to
be very marked, for, even with a strength of 10 grms. per
litre, the scouring of the wool was very incomplete; and,
even using a strength of 5 grms. per litre at temperatures
up to the boiling point, the grease in the fibre was not
thoroughly removed. These results are summarised in
Tables IX. and X.

TABLE IX.—Effect of Borax Solutions (at 140° F.).

As far as the effect on the strength and elasticity of
woollen yarn by borax solutions, it will be seen that there
is no weakening action due to the mild alkaline nature of
the borax.

TABLE X.—Effect of Borax Solutions (5 grms. per litre).

38	212	15.0	47.0	13.0	31.0	4.8	do.

The results of these tests have led me to the statement
that the scouring of the usual grade of woollen yarn is best
conducted by the use of soap solutions. I know it is the
customary practice to employ alkali carbonates in con-
junction with the soap, and on some grades of yarn, to use
even a large excess of alkali. This appears to me to be
bad practice for I have found that soap solutions unaided
by the addition of any alkali give superior results to those
obtained by the use of the latter. Soap solutions appear
to cause the complete emulsification and consequent
removal of the grease, dirt, and iron present in the woollen
yarn, at concentrations and temperatures much below
those required with solutions of soda ash and ammonia
compounds. Soap appears to be the only scouring
agent among those in common use which eliminates
all trace of iron from the wool, and this is a most
important point in proper scouring, though unfor-
tunately one which is too often passed over.

There is a common statement to the effect that the oil

or the emulsion employed for the oiling of woollen stock for spinning should be one that is easily saponified; for that in scouring, the alkali employed causes a saponification of the oil on the fibre, and hence renders it soluble and easily removable. If this idea were a correct one, solutions of soda ash should prove more efficient scouring agents than solutions of soap, as the former possess the necessary alkali to bring about the saponification of the grease; but we find the contrary to be the case, and soap solutions prove the best scouring agents. A careful study of this subject has led me to the opinion that the saponification theory of wool scouring is entirely erroneous. If we bear in mind the fact that the alkaline liquors employed in scouring are comparatively dilute and are used at rather low temperatures, we can readily understand that there would be a very small amount of actual saponification of the oil, especially when we furthermore consider that not caustic but carbonated alkalies are employed; and in the use of soap solutions it cannot be considered that there is any actual saponification of the oil at all.

It is often said that wool-oils should be as free as possible from unsaponifiable matter, such as mineral oils, &c. But I claim this to be erroneous. Wool fat, which is the natural grease in the wool fibre, consists for the most part of unsaponifiable matter, and yet this grease is easily removable by soap solutions. In the ordinary scouring of raw wool there is practically no saponification of the grease, hence the scouring properties of an oil or grease is evidently not conditioned by its saponifiable nature. The scouring quality of a wool-oil is dependent on the readiness with which it forms an emulsion with water and soap or alkaline solutions and not upon its property of being saponified.

This leads me to the expression of another factor which I shall term the "emulsification equivalent" of the oil. Where it is desirable to obtain the emulsification equivalent of a wool-oil or emulsion in practical use on the fibre, I proceed as follows:—A skein of the woollen yarn, spun with the emulsion under examination, is weighed and then scoured for 20 minutes at a temperature of 140° F. in a solution containing 5 grms. of soap per litre; on washing, drying, and reweighing, the total loss on scouring is obtained. A similar weighed skein of yarn is then scoured for 20

minutes in plain water at a temperature of 140° F. which it is dried and reweighed, and the loss determined. The ratio between the first and second values obtained in this manner will give a crude practical idea of the emulsifying property of the oil on the fibre. In the experiments described in the first part of this paper, for example, have the following data:—

Loss with soap solution	5.7 per cent.
Loss with warm water	2.2 "
Emulsification equivalent = $2.2 \div 5.7 = 38$..	"

Therefore, the emulsification equivalent may be taken to represent the ratio between the total amount removable by complete scouring with soap at 140° that removed by emulsification in plain water at the same temperature. If the water completely removed the emulsification equivalent would be 100 per cent.

To give a numerical value to the emulsification equivalent of the oil itself, without special reference to the method which is satisfactory. The best means that I suggest at present is to take a weighed portion of a cloth or skein of woollen yarn free from grease and materials, treat it with the oil or emulsion in question, and reweigh it in order to obtain the amount of oil in the material. This prepared sample is then treated in the same manner as I have already outlined, and the emulsification equivalent of the oil deduced by the method of calculation. In order to render this method accurate and satisfactory, however, there are many conditions to be determined. I am at present engaged on this question, and expect to be able to furnish a complete description of the method and the results obtainable from it at a later date.

In conclusion, let me say that an oil which is easily emulsified with soap solutions at temperatures not higher than 140° F., other conditions being proper, may be considered as a good wool-oil, irrespective of the fact whether it contains unsaponifiable matter or not. Mineral oils and wool-fat, both of which are unsaponifiable, if properly employed, are easily emulsifiable, and may be used advantageously in the preparation of wool-oils.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London W.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs-Bourgeois, Paris (2°).

PLANT, APPARATUS, AND MACHINERY.

ENGLISH PATENTS.

for Cooling Fluids; An Improved Method of —. I. W. Proctor and W. Morgan, Coventry. Eng. Pat. 12,606, June 3, 1904.

with hollow blades is made to rotate in a vessel, and to be heated or cooled, may be caused to circulate in the vessel, and the heating or cooling agent through the hollow blades of the fan, or *vice versa*.—W. H. C.

Towers for Reducing the Temperature of Cooling Water or other Liquids; Impts. in —. J. A. Bell, Beckenham. Eng. Pat. 15,010, July 5, 1904.

This is for the method of feeding the liquid to be cooled to the "mats" of the cooling tower down which it flows. A number of troughs or channels are arranged in the "mats" and are made in two parts, bolted together, with the upper edge of the "mat" held between the two pieces are placed between the edges of the trough "mat," so as to leave spaces through which the liquid passes on to the "mat." The liquid is conveyed transverse main trough and delivered into the pipes by means of pipes.—W. H. C.

g Apparatus; Impts. in —. O. Schmeisser, Stuttgart, Germany. Eng. Pat. 5988, March 21, 1905.

This is for the introduction of additional annular spaces between the distilling and condensing chambers in the apparatus in which the heating and cooling is surrounded one another concentrically. Each such additional chamber is separated by a vertical plate which does not extend quite to the top of the apparatus, leaving an annular opening between the two plates. The vapour given off in the inner of the two passes through this opening, and is condensed in the outer one.—W. H. C.

or Agitating Liquids; Impts. in Dashers or Stirrers for —. M. W. Beemer, New York. Eng. Pat. 15, Jan. 17, 1905.

FIG 1.

has a concave under-surface, and is mounted on a shaft 13; it has a central vertical air-duct 3.

and lateral air-ducts 12, extending through the wings 2. The wings are of a special shape, having their faces formed as shown at 5, 6, 8 and 7 and provided with a sharp edge

FIG 2.

at 9, the object being to throw the liquid away from the wings as the beater rotates and to induce a current of air through the air-ducts.—W. H. C.

Scale from Boilers; Composition for Removing —. A. O. Hamilton, Dundee. Eng. Pat. 2219, Feb. 4, 1905.

The composition consists of from 50 to 200 lb. of sodium hydroxide, 4 to 56 lb. of cutch, and 1 to 20 galls. of glycerin mixed with 40 galls. of water. The mixture is fed into the boiler and the sediment removed in the usual way.—W. P. S.

Jacketed Vessels; Impts. in —. W. A. S. Benson, London. Eng. Pat. 6363, March 25, 1905.

The inner and outer lids of jacketed vessels are arranged so as to be entirely independent of one another, the insulating air layer thus enclosed between them preventing conduction of heat from the one to the other. The lids are attached by means of "lugs" and "pins" instead of hinges. By depressing a push-piece, connected to the inner lid and passing through an opening in the outer one, the two lids can be opened simultaneously.—W. H. C.

Gases by a Liquid under the Action of the Silent Electric Discharge; Apparatus for Absorbing —. A. de Hemptinne, Ghent, Belgium. Eng. Pat. 7101, April 4, 1905.

A SERIES of parallel revolving metal plates, with discs of insulating material between adjacent ones, is arranged within a fixed casing or within a vessel that revolves with the plates on a horizontal axis. Alternate metal plates are connected to one pole, and the remainder to the other pole of a source of electric current, in order to establish a silent electric discharge between the plates. The latter are partially immersed in the absorbing liquid, which is carried round by small troughs attached to the casing and delivered on to the upper portions of the plates, so that a thin layer of liquid is maintained on the plates, and the gas to be treated is thus brought into intimate contact with the liquid. An electro-magnetic device, working automatically, maintains a constant pressure of gas in the apparatus during the absorption.—B. N.

UNITED STATES PATENTS.

Vacuum-Pan. H. W. Buschmeyer, Louisville, Ky. U.S. Pat. 789,793, May 16, 1905.

THE claim is for a metallic hanging basket A with a corrugated bottom, which is fitted steam-tight into

the outer walls of the pan and has a space below for the introduction of the heating agent.—W. H. C.

Dryer. W. R. Macklind, Mineralpoint, Mo. U.S. Pat. 789,984, May 16, 1905.

THE sludge to be dried is fed from the hopper A by the reciprocating agitator B on to the vibrating table C, from which it is fed on to the heated rotating cylinder D. The dried material is removed by the scraper E and the brush F, and the condensed water is led off from the interior of the cylinder D by a siphon G, one limb of which passes through a stuffing-box in the end of the cylinder.—W. H. C.

Dryer and Separator. J. Waterhouse, New York. U.S. Pat. 790,605, May 23, 1905.

THE separator consists of a pear-shaped casing provided with a charging opening and cover near the top, with two discharge openings of different diameters at the bottom, and with one or more glass-covered sight holes. The separating agent, which may be a current of compressed air, is delivered in a downward direction into the casing by two pipes, one of which is of smaller diameter than the other and enters the casing at a point lower down. The waste air leaves at the top by a pipe which takes a sharp bend downwards and is provided with a sight tube.

—W. H. C.

Separating Apparatus; Centrifugal — E. Seger, Stockholm. U.S. Pat. 790,981, May 16, 1905.

SEE Eng. Pat. 458 of 1904; this J., 1904, 363.—T. F. B.

GERMAN PATENTS.

Centrifugal Machine for the Separation and Washing of Substances Crystallising out from Solutions. F. Scheibler. Ger. Pat. 158,788, Feb. 28, 1903.

THE drum of the centrifugal machine is double-walled, but only the inner wall is perforated. Around the drum are arranged a number of "protecting rings" or annular division plates, which are movable vertically, and project below into the annular discharge-channels at the bottom

of the drum casing, each of these division-plates, when in its lowest position, closing the discharge-channel in which it projects. The liquid expelled by the centrifugal force through the perforations in the inner wall of the drum, collects in the annular space between the two walls, and is then forced upwards, being finally collected in any one of the discharge-channels by raising the corresponding division-plate.—A. S.

Centrifugal Machine; Process of and Device for Collecting in Separate Outlet Channels the Liquids Separated in — W. Gautenberg. Ger. Pat. 157,926, June 1904.

BETWEEN the inner perforated drum of the centrifugal machine and the outer casing is interposed a second perforated drum. The bottom of this intermediate drum is provided with outlet openings near its outer edge, whilst the centre of it has a flange forming a hollow cone, which means of a lever can be brought at will into contact with a corresponding cone on the driving shaft. By this arrangement the two perforated drums can be made to rotate together, in which case the liquid passes through the perforations in the second drum; or the inner drum only is made to rotate, when the liquid flows down the inner wall of the second drum into a separate outlet channel.—A.

Packing Blocks for Absorption Towers and Distillation Columns. R. Sauerbrey and A. Wünsche. Ger. Pat. 158,715, Nov. 13, 1903.

THE blocks have the form shown in the figure, each being composed of a head piece (a) with a dish-like depression on its upper surface, a base-piece (b) hollowed out on its lower side, and connecting walls (d), with channels (c) leading from the upper face of the head-piece to the walls (d). Each block can be divided into two or more pieces by cuts through its longitudinal axis, and the blocks are disposed in the tower or column, that enclosed spaces are left between several head-pieces.—A. S.

II.—FUEL, GAS, AND LIGHT.

Iron Sulphides, and the Purification of Coal Gas by means of Ferric Hydroxide. L. Gedel. J. Gasbel., 1905, 412—417, 428—432.

I.—IRON SULPHIDES FORMED BY WET METHODS.

Alkalinity maintained.—Ferric sulphide was formed by gradually adding ferric chloride solution to freshly prepared ammonium sulphide solution, so as finally to leave an alkaline liquid. The black precipitate was washed as to avoid oxidation, and a portion was dried at about 100° C., and then treated with carbon bisulphide. It was found, however, that no sulphur was extracted, since ferric sulphide is stable at that temperature. If ferric sulphide had not been formed, the only other result possible would have been the formation of a milky precipitate of ferrous sulphide and free sulphur; $(2\text{FeS} + \text{S})$. This possibility is, however, excluded, since ferric sulphide in presence of free sulphur, on but slight rise of temperature, yields some iron disulphide, insoluble in hydrochloric acid, and none was present; moreover, ferrous sulphide itself dissolves with evolution of hydrogen sulphide and no separation of sulphur, whereas the ferric sulphide actually formed, decomposes with liberation of sulphur, as follows:— $\text{Fe}_2\text{S}_3 + 4\text{HCl} = 2\text{FeCl}_2 + 2\text{H}_2\text{S}$. A more convenient method of preparing ferric sulphide was found in the treatment with ammonium sulphide of an alkaline (ammoniacal) ferric solution, formed by

ion of ammonium tartrate and ammonia to ferric sulphide solution.

was further found that on submitting ferric sulphide oxidation with moist air, the reaction proceeds in as follows:— $\text{Fe}_2\text{S}_3 + 3\text{O}(\text{air}) = \text{Fe}_2\text{O}_3 + 3\text{S}$. At the time a minute quantity of ferrous sulphate is formed (Wagner, J. Gasbel, 1869, 180). Ferrous sulphide in presence of free sulphur, collaterally formed, on slight increase of temperature through chemical action, would have combined with a portion of that sulphur to form some iron sulphide which remains unoxidised by the air. On heating the mixture $2\text{FeS} + \text{S}$ at about 100°C ., the complete reaction ($2\text{FeS} + \text{S} = \text{FeS}_2 + \text{FeS}$) takes place, the whole of the free sulphur being absorbed.

Slight Acidity maintained.—Ferric chloride was used with ammonium sulphide, so that slight acidity was maintained. Sulphur separated and a precipitate of FeS was formed (see a).

Slight Acidity and increased Temperature.—The reaction referred to under (b) recurs, but at the raised temperature, a further reaction takes place $2\text{FeS} + \text{S}$ converted into $\text{FeS}_2 + \text{FeS}$. No sulphur could then be attracted by carbon bisulphide, and on treating with hydrochloric acid, an insoluble residue of iron disulphide remained (see a). It was found that if ferrous sulphide, instead of ferric, was used, and treated with ammonium sulphide, it became converted into ferric sulphide.

FERRIC HYDROXIDE AND HYDROGEN SULPHIDE.
In presence of acid.—Hydrogen sulphide first rendered acid by passing it through dilute hydrochloric acid was passed over pure ferric hydroxide for several hours. No ferric sulphide was formed, but only the free $2\text{FeS} + \text{S}$, and, from this, in consequence of the chemical reaction, also some iron disulphide (FeS_2) was formed. After drying at 100°C ., the product consisted entirely of iron disulphide.

In absence of acid but moisture present.—Practically the same reaction in (A) repeated.

Absence of acid but moisture and some air present.—In presence of air proved practically without influence, the reaction being substantially that in (A) and (B).

Method of Determination.—(1) Estimation of total iron sulphur by direct oxidation with bromine. (2) Determination (i.) of the hydrogen sulphide liberated by the action of hydrochloric acid, and (ii.) of the iron disulphide remaining undissolved; the first representing FeS , and the second, FeS_2 present. (3) The free sulphur, by reaction with carbon bisulphide.

In presence of ammonia.—The hydrogen sulphide first passed through ammonium sulphide and thus rendered alkaline, and then through the ferric hydroxide. The product now consisted solely of ferric sulphide, Fe_2S_3 , exposing some of each of the two products (i.) under acid treatment, and (ii.) under alkaline treatment, to oxidation in the air for several days, it was found that in case (i.) the iron disulphide had remained unchanged, and was also insoluble in dilute hydrochloric acid whilst in (ii.) the product was completely oxidised to ferric oxide with liberation of sulphur. On treating a portion of it (the ferric sulphide) with dilute hydrochloric acid, hydrogen sulphide was evolved, sulphur separated, and the iron went into solution.

"GAS OXIDE" was now examined fresh from the purifier. The results show that no insoluble iron was present, representing iron disulphide in the product, but in consequence of the presence of ammonia in the gas passed into the purifiers, hydrogen sulphide is removed by the formation of ferric sulphide, this by oxidation with moist air afterwards yielding smoothly, sulphur and ferric hydroxide.

Coal, Slack, Ores, Minerals or Substances of Different Specific Gravity: Separating —. T. A. Johnson, Northwich, Cheshire. Eng. Pat. 13,765, June 17, 1904.

THE material is made to fall down a vertical or nearly vertical shoot containing water or other liquid, and a current of air or gas is forced into the liquid at the bottom of the shoot. The upward flow thus produced, carries the lighter portions of the material over a spout at the top of the shoot on to a drainer, and then into a suitable receptacle. The heavier portion falls to the bottom of the vessel and is carried away by a conveyor, or it falls into a "shot flask device," from which it is finally discharged.—W. H. C.

Coke; Manufacture of — and Furnaces, Ovens and Apparatus therefor. J. Armstrong, London. Eng. Pat. 14,157, June 22, 1904.

COAL, soft coke or anthracite, with or without the addition of pitch or bituminous material, is reduced to a fine powder and charged into upright furnaces, tapering towards the top, and provided with external flues heated by gas. The coking operations are divided into three distinct stages. In the first stage, the gases are distilled off from the coal dust in the upper part of the furnaces at a very low temperature, which also favours the complete extraction of ammonia. As the coal descends, it enters the second zone, around which the heating flues are constructed. The coal in this zone becomes gradually coked, and, owing to the high temperature and the pressure of the column of fuel above, the coke is rendered very hard and dense. The coke then passes down to the third zone, where it is cooled by a water-jacket or gas and air-flues, thus raising steam for preheating the mixture of water-gas and air. The coke may also be cooled by blowing steam through it, hydrogen being formed. The coke is removed from time to time below the furnaces.—R. L.

Carburetted Air or Gas; Apparatus for —. M. Steel and R. Thornton, Gosforth, Northumberland. Eng. Pat. 10,677, May 9, 1904.

THE carburettor, which is adapted for use in connection with internal combustion engines, comprises a closed vessel supplied through a valve in its bottom with "hydrocarbon." The air inlet is connected by means of a mercury lute with a floating chamber provided with a series of outlets consisting of small telescopic tubes extending downwards into the hydrocarbon, or of rows of graduated perforations in a flange projecting downward from the float. As the float rises or falls, air can thus be introduced at a certain predetermined depth into the hydrocarbon. The hydrocarbon-supply valve is normally kept closed by a spring, but is opened by an adjustable rod fixed on the float, when the latter falls below a certain level. Instead of this valve a separate supply vessel with floating arrangement may be employed to control the supply of hydrocarbon.—R. L.

Peat; Obtaining Producer Gas and Electrical Energy from —. F. T. Warburton, London. Eng. Pat. 11,917, May 25, 1904.

GAS is generated by combustion in a producer, of dried or compressed peat, in a layer from 3 ft. deep upwards, air being introduced from below. The gas thus obtained is used in gas engines for generating and transmitting electrical energy.—R. L.

Gas Producing Plant; Impts. in —. J. Dunlop, Handsworth and Kynock, Ltd., Witton, Staffs. Eng. Pat. 13,517, June 15, 1904.

THE object of this invention is such improved arrangement and construction, that the action of generating the gas, and utilising it in a gas-motor, will be more perfect than hitherto in gas-plants. The producer consists of a cylindrical shell of metal lined with firebricks, having at its lower end a movable hearth lined with firebrick, and provided with an ash-pit door. The gas-outlet pipe is arranged in the higher part of the generator, and is surrounded by a jacket-pipe, which serves for raising steam and heating air. The inlet branch to the jacket-pipe is fitted with an adjustable plate for regulating the quantity of air, and also with an intermittent siphon with regulating arrangement, so that the quantity of water admitted along with the air may be such as to exactly suit the rate of gas production and the quality of fuel used. The outlet pipe of the jacket communicates with the closed ash-pit, and the mixture of air and steam passes from the ash-pit through the incandescent zone of the fuel. The gas issuing from the producer, after passing through a cooler-scrubber, is led through a gas and air regulator, which is divided into two chambers for gas and air, communicating by a piston or diaphragm regulated by a weight or spring. The action is such that when the motor draws in the mixture of air and gas, the proportions will be automatically adjusted whatever be the condition of the fire in the generator.

—R. L.

Gas Producers; Impts. in —. G. Hatton, Brierley Hill, Staffs. Eng. Pat. 13,877, June 20, 1904.

THE producer consists of an upper combustion chamber containing the fuel, a lower chamber in which a blast of air under pressure is maintained, and a water-sealed ash-pit. A grate having the form "of a section of an inverted cone" supports the fuel. The lower ends of the fire-bars rest on a central ring, through which a blast pipe, provided with covered top and suitable openings, extends vertically upwards. A rotary motion is imparted to the blast pipe by suitable gearing, whereby a twofold object is attained, viz., the blast is distributed equally to all parts of the producer in turn, and the clinker from the grate is crushed by means of projecting teeth on the rotary part of the blast-pipe, which rotate in close proximity to stationary teeth on the ring supporting the grate. The upper portion of the producer is lined with firebrick; the lower chamber, which is movable vertically, is sealed on its top by a circular water lute, whilst it dips, when in working position, into the water contained in the ash-pit. The blast-pipe is also provided with tuyères in its lower part. By this means the blast is supplied below and through the fire-bars, as well as up the central pipe. By turning off the blast and raising the lower chamber, the grate and blast-pipe are rendered easily accessible.

—R. L.

Gas; Apparatus for Producer or Water. —. W. F. Mason, Manchester. Eng. Pat. 15,821, July 16, 1904.

SIDE chambers are provided in a gas producer, which are partially cut off from the main portion of the interior of the apparatus by means of firebrick walls. The gases after passing through the incandescent fuel, leave the producer through openings in the tops of the side chambers. These openings are of comparatively large area, and situated above the upper level of the fuel. The hydrocarbons, which are given off by the burning fuel, are thus prevented from making their final exit until the desired decomposition has taken place.—R. L.

Gas Producers; Impts. in —. A. G. Bloxam, London. From W. H. Bradley, Bellevue, Pa., U.S.A. Eng. Pat. 16,895, Aug. 2, 1904.

A GAS producer is placed so that the lower end of its inclined partition is arranged in the middle of the trough to give direction to the ashes. The pipes for the supply of air and steam to the producer are arranged above across the partition. The trough can thus be cleaned, the ashes discharged from the producer and drawn out in a direction parallel with the pipes.—R.

Gas; Steam Generator for Water. — Producers. Vogelsang and J. Born, of the Dresdner Gasmotoren-Fabrik vorm. Moritz Hille, Dresden. Eng. Pat. 13,517, Jan. 3, 1905.

THE steam generator which permits of rapid evaporation of water, consists of an upright vessel tapering towards the top, in which "tongues" are arranged projecting the side walls and extending between each other. The vessel is suspended in the ash-trap through which the gases from the generator furnace pass. Water is made to drip into the steam generator and down over the tongues, these being inclined and offering a large surface to evaporating water. The steam raised ascends through passages along the side walls and is conducted to the generator furnace. For the purpose of removing the scale with which the tongues become encrusted after some time, the steam generator is constructed in halves which can be bolted together, and can be unbolted for cleaning.—R.

Gas Washer Scrubbers; Impts. in —. J. H. Drake, London. Eng. Pat. 13,236, June 11, 1904.

A FLANGED projecting pipe is fixed to the stationary division plate of a rotary washer scrubber. Another flanged pipe which overlaps the former is fixed to the revolving frame plate, and bolted to it is a ring of interchangeable brushes which are in contact with the stationary flange pipe around which they revolve. Should the revolving shaft be moved from its central position, no gas can enter the washing, the flexible brushes being always in contact with the stationary portion.—R. L.

Gas; Purification of Coal —. X. Roux, Paris, France. Gonin and W. Thomson, London. Eng. Pat. 13,777, June 13, 1904.

GRANULAR or lumpy peat is reduced to powder, treated with a 2 to 12 per cent. solution of alkali, which it readily absorbs. The mass is then dried. It is next charged into wire baskets, and a number of these baskets are arranged in a casing through which the crude gas passes. The sulphuretted hydrogen and ammonia are taken up by the peat, which is said to be converted into a valuable fertilising material.—R. L.

Gas Washing, Cleaning and Cooling Towers. —. W. D. A. Glasgow. Eng. Pat. 15,688, July 6, 1904.

CLAIM is made for the combination of scrubber and "bubble-washers" in a tower. The tower is packed with coke and has bubble-washers in convenient positions, as described. The gas enters the bottom washer through holes in the bottom plate, and ascends to a washer arranged in the middle of the tower, through a column of coke or other packing material moistened by a spray of the washing liquid. It then ascends another column of coke and a washer on the top of the tower, thus coming thoroughly into contact with the washing liquid.—R. L.

Candles and the like; Wicks for —. V. Pferschke, Mülhausen, Alsace. Eng. Pat. 29,546, Dec. 31, 1903. Under Int. Conv., April 21, 1904.

SEE Fr. Pat. 343,086 of 1904; this J., 1904, 978.—T. J. B.

Candles; Manufacture of —. A. Haase, Hamburg. Eng. Pat. 3438, Feb. 18, 1905.

TO facilitate the lighting of candles or tapers, the free end of the wick is treated with a solution of celluloid in an equal quantity of acetone. The acetone evaporates and the wick remains coated with celluloid, and is now easily inflammable.—R. L.

UNITED STATES PATENTS.

Art of Controlling Furnace — J. W. Dougherty, Leetont, Pa. U.S. Pat. 789,844, May 16, 1905.

formation of explosive gas mixtures in blast-furnaces avoided by replacing the air in the furnace and its connections by inert gases or steam, either by blowing, for instance, into the furnace from the bottom, or by filling the top and the connecting pipes with steam before turning on the blast, thus driving forwards a quantity of steam in sufficient quantity to prevent explosion, out of the furnace gases.—R. L.

Producing and Consuming Apparatus. C. Ellis, Assignor to Eldred Process Co., New York. U.S. Pat. 790,453, May 16, 1905.

apparatus consists of a gas-furnace fitted with regenerators, and a gas producer to supply the heating. The regenerators through which the gases of combustion pass, may be so located that one of them heats the gases richer in carbon dioxide. Means are provided for returning the waste gases from the regenerators to the combustion zone of the producer, and for admitting separately, products of combustion and a mixture of air as to the regenerators by means of a reversing valve mechanism.—R. L.

Apparatus for Making — O. N. Guldlin, Fort Wayne, Ind. U.S. Pat. 790,296, May 23, 1905.

Eng. Pat. 26,769 of 1902; this J., 1903, 1341.—T. F. B.

Condensing Apparatus. O. N. Guldlin, Fort Wayne, Ind. U.S. Pat. 790,297, May 23, 1905.

surrounding the gas-exit pipe, enters another annular helical chamber surrounding the generator and passes thence underneath the grate of the chamber. W. H. C.

Gas-Producer Apparatus — C. Ellis, Assignor to Eldred Process Co., New York. U.S. Pat. 790,487, May 23, 1905.

The apparatus consists of a producer constructed to maintain a deep bed of fuel and provided with a water-jacket for the withdrawal of the ash in an undisturbed and finely-divided condition. The blast is produced by a fan, which draws the products of combustion from a furnace by means of a pipe, and, after admixture with suitable proportions of air and steam, delivers it to the tuyeres.

W. H. C.

Gas; Process of Generating Combustible — C. Ellis, Assignor to Eldred Process Co., New York. U.S. Pat. 790,488, May 23, 1905.

The operation of gas producers is regulated by supplying as a blast, a mixture of air with the products of combustion. The proportion of the products of combustion, and consequently of carbon dioxide is increased temporarily, when fresh fuel is charged, so that the temperature of the producer is lowered and a more uniform distillation of the hydrocarbons of the fuel effected.

—W. H. C.

Gas; Process of Manufacturing Combustible — C. Ellis, Assignor to Eldred Process Co., New York. U.S. Pat. 790,489, May 23, 1905.

THE process consists in passing through a deep bed of

gas enters the first multitubular condenser 1 by the top, and is made to flow in the direction shown by the arrows, by the baffle plates 9, passing afterwards through condensers 2 and 3. A regulated current of air enters condensers 1 and 2 at the bottom by the openings 5, runs up the tubes and away by the outlets 6, controlled by dampers 7. The upper ends 8 of the tubes project through the upper tube-plate into the upper chamber containing water, which overflows down the tubes as a jacket. In the third condenser 3 the cooling is effected by water which flows up through the tubes and then serves to cool condensers 1 and 2.—W. H. C.

Generator. G. Apfel, Chicago, Ill. U.S. Pat. 790,418, May 23, 1905.

generator consists of a chamber of refractory material containing a fuel-charging tank above and a water seal, in the centre of which is a cone projecting upwards to the generator. The gas is taken away from the upper part of the chamber by a pipe provided with a number of horizontal plates or "shelves." The mixture of air and fuel, after passing through an annular helical conduit

fuel, in a producer, a mixture of air and of alternately intensely heated and cooled products of combustion, the object being to so regulate the temperature of the producer that slagging or clinkering of the fuel or ash does not occur.—W. H. C.

FRENCH PATENTS.

Fuel [Briquettes]; Combustible Mineral — Cie des Charbons et Briquettes de Blanzey et de l'Ouest. Fr. Pat. 349,222, Dec. 20, 1904.

Hydrocarbons; Process for the Oxidation (and Distillation) of — [Production of Fatty Acids]. Soc. Anon. des Combustibles Industriels. Fr. Pat. 349,214, Dec. 19, 1904.

THE process consists in introducing into the hydrocarbons, during the distillation, a current of air which has been dried, freed from carbon dioxide, heated, and in some cases enriched by the addition of oxygen or ozone. It is claimed that the hydrocarbons are oxidised, and that the heat generated causes the distillation to continue and to take place at a lower temperature, especially if a vacuum is maintained in the apparatus. The products of distillation are of a higher density and of more value, especially as lubricants, than those produced by distillation in the ordinary way. The pitch is improved, and is particularly suitable for the manufacture of briquettes, and further, by the employment of suitable pressure, bodies approximating in composition to fatty acids are said to be obtained.—W. H. C.

IV.—COLOURING MATTERS AND DYE STUFFS.

Naphthalene; Oxidation of —, to *Phthalic Acid* by means of Concentrated Sulphuric Acid in Presence of Oxides or Salts of Rare Earths. H. Ditz. Chem.-Zeit., 1905, 29, 581—582.

In place of mercury and its salts used in the production of phthalic acid by the action of sulphuric acid on naphthalene, the author has tried the catalytic action of compounds of rare earths obtained as by-products in the manufacture of thorium nitrate, such as the oxalates, carbonates and hydroxides of cerium, lanthanum, neodymium, praseodymium and yttrium. For this purpose naphthalene (25 grms.) was heated in a retort with excess of concentrated sulphuric acid (375 grms.) and the oxides or salts of rare earths (15 grms.). Evolution of gas commenced at a temperature slightly above 100° C., proceeding more rapidly at 220° C. At 230° C. the mixture began to boil, and on gradually raising the temperature to 300° C. or above until the mass became viscous, the melt turned dark and evolved sulphurous, sulphuric and carbonic acids. The distillate consisted of sulphuric and phthalic acids, the latter mainly as anhydride, but containing some sulphonic acid. The velocity of the reaction is not, however, as great, nor the yield as favourable as with the use of mercury as catalytic agent.—D. B.

Diamines; Action of Formaldehyde and Sodium Bisulphite on —. M. Prud'homme. Bull. Soc. Ind. Mulhouse, 1905, 75, 43—45.

THE base produced by the action of sodium bisulphite and formaldehyde upon benzidine (this J., 1905, 433), of the formula $\text{H}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{SO}_3\text{Na}$ or $[\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{N} : (\text{CH}_2 \cdot \text{SO}_3\text{Na})]_2 \cdot \text{CH}_2$, is slowly acted upon by a mixture of nitrous and hydrochloric acids.

The greenish-yellow diazo chloride formed gives salt-R a dyestuff which dyes cotton from alkaline bath in shades of violet-blue which are rather than those dyed by the corresponding benzidine pound. From an acid bath, the new dyestuff dyes in crimson shades, dyeing much more easily than corresponding benzidine derivative. The azo dy. derived from the new base and naphthionic acid orange, that produced from benzidine and the same being a red (Congo Red).

Noelting finds that, whereas the base produced by the action of formaldehyde upon benzidine is acted upon with partial elimination of the formaldehyde, by an acid, and converted to some extent into the ortho-tetrazodiphenyl base, the new base withstands such treatment and gives a diazo derivative which on combination with a series of new sulphonated dyestuff compounds, possess the property of dyeing both cotton and wool.

ENGLISH PATENTS.

Indigo or Homologues or Derivatives thereof; Manufacture of —. L. Lilienfeld, Vienna, Eng.

SEE Fr. Pat. 343,078 of 1904; this J., 1904, 980.—T.

Dyestuffs [Orazine and Azine Dyestuffs] of the Anth-
Series; Manufacture of New —. O. Imray, Lo
 From Farbw. vorm. Meister, Lucius u. Brüning, Ho
 on-Maine, Germany. Eng. Pat. 14,970, July 4.

New dyestuffs are prepared by condensing *o*-aminophenol or its homologues or derivatives, or an aromatic *o*-diamine or its mono-alkyl or mono-aryl substitution product with a derivative of alizarin containing a hydroxyl or amino-group in the 4-position. The hydrogen atom at the latter group may or may not be replaced by an alkyl or aryl groups. The products are probably of the following types :—

For example, 18 kilos. of purpurin are heated for 8 hours under pressure at 140° C. with 8 kilos. of *o*-cresol, 13 kilos. of boric acid and 60 litres of water. The product is transformed by sulphonation into purpuric acid, which dyes unmordanted wool in blue-violet shades. The purpurin may be replaced by amino-alizarin, dimethylaminoalizarin or 1,2,4-triaminoalizarin. Purpurin-3-sulphonic acid and *o*-aminoalizarin yield a dyestuff which gives blue shades on unmordanted or chrome-mordanted wool. Similar results are obtained with purpurins sulphonated in the non-hydroxylic nucleus. With purpurin and *o*-aminodiphenylamine a dyestuff is obtained which, after sulphonation with 50 per cent. fuming sulphuric acid at 20°–40° C., dyes chrome-mordanted wool in very fast blue shades. A similar result is obtained with *o*-phenylenediamine. —E. F.

Colouring Matters [Azo Dyestuffs]; Manufacture of oxy-azo ——. T. R. Shillito, London. From Aniline Colour and Extract Works formerly Geigy, Basle, Switzerland. Eng. Pat. 15,025, J 1904.

SULPHONIC acids of 1-amino-2-naphthol are diazotized by the process described in Eng. Pat. 10,235 of 1904 (cf. 1905, 433), and then combined with naphthols and monosulphonic and carboxylic acids, aminonaphthols, their sulphonic acids, dihydroxynaphthalenes and sulphonic acids, *m*-hydroxyphenols, *m*-aminophenols and *m*-diamines. The products dye wool from an acid bath in brick-red to dark violet-black shades, which on treatment with sodium sulphate turn to reddish to bluish or greenish black on subsequent treatment with potassium bichromate, and to reddish violet to blue on treatment with copper sulphate. The shades show, after treatment with bichromate, great fastness to milling and to potting; all are very fast to light, after treatment with bichromate or copper sulphate. For example, 11 kilos. of resorcinol

os. of sodium carbonate are dissolved in 150 litres of water and 25 kilos. of dry, powdered 1-diazo-2-naphthol-sulphonic acid are added with stirring. The formation of the dyestuff commences immediately and is complete in several hours. The product dyes wool from an acid bath in dark brown shades, which become black on treatment with bichromate and dark brown with copper sulphate. The product is obtained from *m*-toluylenediamine and 1-diazo-2-naphthol-sulphonic acid and 1-diazo-2-naphthol-4-sulphonic acid dyes wool in reddish-brown shades, which become black after treatment with bichromate, and dark brown with copper sulphate. From 1-amino-8-naphthol-sulphonic acid and 1-diazo-2-naphthol-4-sulphonic acid dyestuff is obtained yielding reddish-blue shades on wool, turned to olive by potassium bichromate, and to black by copper sulphate.—E. F.

1-diazo-2-oxynaphthalene-sulphonic Acid or Sulphonic Acid of the Nitronaphthalene-1,2-diazo-oxide; Manufacture of — [Azo Dyestuffs]. T. R. Shillito, London. From the Aniline Colour and Extract Works, formerly J. R. Geigy, Basle, Switzerland. Eng. Pat. 118, July 11, 1904.

1-diazo-compound (or diazo-oxide) obtained by diazo-1-amino-2-naphthol-4-sulphonic acid by the process described in Eng. Pat. 10,235 of 1904 (this J., 1905, 433), is nitrated in the usual manner without decomposition, forming a stable nitro-diazo-compound (or nitro-oxide). For example, 25 kilos. of dry, powdered 1-diazo-2-naphthol-4-sulphonic acid are added gradually with stirring to 75 kilos. of concentrated sulphuric acid. A cooled mixture of 7 kilos. of 96 per cent. nitric acid and 4 kilos. of 100 per cent. sulphuric acid is then slowly added, the temperature being kept at 0°–5° C. by external cooling. Stirring is continued for some hours at the same temperature, and the whole then poured on to 100 kilos. of water. The nitro-compound separates immediately. It is very soluble in water. When combined with certain metallic salts it forms valuable nitro-*o*-hydroxyazo-dyes, the dyeings of which on wool become very fast on subsequent treatment with potassium bichromate.—E. F.

1-naphthylaminesulphonic Acids; Manufacture of — C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 15,624, July 13, 1904. U.S. Pat. 344,810 of 1904; this J., 1904, 1210.—T. F. B.

Indigo Series; Manufacture of Violet-Blue Colouring Matters of the — [Anthracene Dyestuffs], and Intermediate Products of the said Manufacture. J. Y. Benson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 538, July 26, 1904.

U.S. Pats. 786,085 and 787,859 of 1905; this J., 1905, 494 and 541.—T. F. B.

UNITED STATES PATENTS.

Indigo; Alizarin — [Anthracene Dyestuff]. R. E. Smith and A. Fischer, Elberfeld, Germany, Assignors Farbenfabriken von Elberfeld Co., New York. U.S. Pat. 790,079, May 16, 1905.

Indigo Blue is treated with formaldehyde in acid solution. The product combines with alkali bisulphites

yielding compounds soluble in water, which produce grey to black shades when printed on cotton together with chromium acetate.—E. F.

Dyestuff; [Sulphide Dyestuff]; Blue Sulphate —, and Process of Making same. J. Abel and A. Lüttich, Assignors to Badische Anilin u. Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 790,167, May 16, 1905.

THE alkali salts of *p*-amino-*p*-hydroxydiphenylamine, *p*-phenylamino-*p*-hydroxydiphenylamine, their homologues or derivatives are heated with sulphur. The products are soluble in aqueous sodium sulphide solution forming pale yellow solutions, without the intermediate formation of a blue liquid. From these solutions, when hot, vegetable fibres take up a leuco-compound, which on exposure to the air, becomes blue to violet-blue in the case of the dyestuff from the *p*-amino-compound and pure blue in the case of that formed from the *p*-phenylamino-compound.—E. F.

Dyestuff, Nitroazo — [Azo Dyestuff]; and Process of Making same. J. Hagenbach, Assignor to Aniline Colour and Extract Works, formerly J. R. Geigy, Basle, Switzerland. U.S. Pat. 790,363, May 23, 1905.

SEE Eng. Pat. 15,418 of 1904; preceding these.—T.F.B.

Dyestuff, Azo, and Process of Making Same. J. Hagenbach, Assignor to Aniline Colour and Extract Works, formerly J. R. Geigy, Basle, Switzerland. U.S. Pat. 790,364, May 23, 1905.

SEE Eng. Pat. 15,025 of 1904; preceding these.—T.F.B.

FRENCH PATENT.

Indigo White; Manufacture of — Badische Anilin und Soda Fabrik. Fr. Pat. 349,379, March 22, 1904.

SEE Eng. Pat. 6226 of 1904; this J., 1905, 127.—T. F. B.

GERMAN PATENTS.

Hydroxyanthraquinone Methyl Ethers; Method of Preparing — Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 156,762, Sept. 8, 1903.

THE *α*-sulphonic acid groups of anthraquinone-*α*-sulphonic acids may be replaced by methoxy groups by warming with methyl alcohol in presence of alkali hydroxides. 20 kilos. of the sodium salt of anthraquinone-*α*-monosulphonic acid are heated with 250 litres of methyl alcohol and 25 kilos. of sodium hydroxide, until the greater part of the acid has disappeared, when the product is poured into water, and the *α*-methoxyanthraquinone filtered off and washed. The dimethyl ethers of Chrysazin and Anthrarufin can be prepared similarly from 1,8- and 1,5-anthraquinonedisulphonic acids.—T. F. B.

Indigo; Process for Purifying — G. Ullmann. Ger. Pat. 156,829, Nov. 17, 1903.

THE solution of indigo in a mixture of sulphuric and acetic acids is treated with a sufficient quantity of an acetate or sulphate to convert the whole of the sulphuric acid into bisulphate; the acetic acid is then distilled off, and the residue treated with water to remove the bisulphate. This process permits the recovery of the acetic acid in a simple manner, without fear of sulphonating the indigotin.—T. F. B.

Dyestuff Containing Sulphur [Sulphide Dyestuffs]; Process for Preparing a Yellow Cotton — Farkwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 157,103, Dec. 15, 1903. Addition to Ger. Pat. 156,177, Dec. 15, 1903 (see this J., 1905, 434).

THE product obtained by melting 2,2'-diamino-4,4'-oxaltoluide with two mols. of *m*-toluylenediamine is heated with sulphur to temperatures above 170° C. The resulting dyestuff dyes cotton yellow shades, which are faster to alkalis than those given by the dyestuff from diamino-oxaltoluide alone.—T. F. B.

1.4-Diaminoanthraquinone or 1.4.5.8-Tetra-aminoanthraquinone; Process for Preparing —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 156,803, May 8, 1904.

1.4-DIAMINOANTHRAQUINONE is produced by oxidising the diazonium derivatives of *a*-aminoanthraquinone (e.g., by means of a hypochlorite or permanganate) to the corresponding nitramine, nitrating, and then reducing the 1.4-nitronitramine. 1.4.5.8-Tetraaminoanthraquinone is obtained in a similar manner from 1.5- or 1.8-diaminoanthraquinone.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Cotton Tissues; Maltng Starched —. A. Scheurer. Bull. Soc. Ind. Mulhouse, 1905, 75, 39—42.

THE presence of boiled malt in the bath slightly diminishes the action of malt upon starched tissues. Soap, even in minute quantity, exercises an unfavorable influence upon the starch-hydrolysing power.—E. B.

Dying Process; Dichroism in connection with the —. K. Fox. Z. Farben-u. Textil-Ind. 1905, 4, 257—259.

THE author finds that double refraction is usually weaker in wool than in cotton or woody fibre, that indigo causes strong dichroism in vegetable fibres, and that wool and silk may be rendered dichroic by dyeing. The animal fibres show very strong dichroism if dyed, for instance, with gold chloride. Ramie dyed with basic dyestuffs without mordants, shows strong dichroism. No dichroism could be observed if the fibre were previously mordanted with tannin and tartar emetic. Acid dyestuffs from a neutral bath, without mordant, caused distinct dichroism in the ramie fibre. When the fibre had previously been mordanted with alum, the dichroism was weaker. Direct cotton dyestuffs, dyed from a neutral or weakly alkaline bath, caused strong dichroism. Unmordanted cellulose fibre, dyed with basic dyestuffs, showed dichroism which disappeared on subsequent treatment with tannin. When the tannin-lake, so formed, was dissolved by the action of acetic acid for a short time, and the whole then dried, the dichroism reappeared. Primuline shows strong dichroism on cellulose fibre, which does not disappear by diazotising on the fibre and combining with *a*-naphthol. The author considers dichroism to be due to the disposition of minute crystals of the dyestuffs in a geometrically regular manner in the interstices of the fibre.—E. F.

Dyes; Brown — obtained by combining Substantive Dyestuffs with different Diazo Derivatives. L. Caberti, C. Barzaghi and P. Roggeri. Rev. Gen. Mat. Col. 1905, 9, 153—154.

THE authors have tried the effect of developing some direct cotton dyestuffs by means of various diazo derivatives in order to produce brown shades. The process consists in padding the material in a solution of the dyestuff containing an alkali such as sodium phosphate or caustic soda, and also tragacanth solution; this solution is used at a temperature of 60—70° C. The material is dried in the hot blue, passed through the diazo solution contained in another padding machine, and then washed and dried. Some of the results obtained were as follows:—Diazotised paranitraniline gave a fine puce colour with Diamine Nitrazole Brown B and a beautiful cutch brown with Diamine Nitrazole Brown B.D. Diazotised *p*-nitro-*o*-anisidine gave a good brown with Diamine Nitrazole Brown B. Diazotised metanitraniline gave a full orange-brown with the B.D. brand, and a bright reddish-pace with the B. brand. Diazotised *m*-aminoazotoluene gave a reddish-brown with the B. brand. Diazotised benzidine and diazotised nitrotoluidine gave lighter and yellower shades with the B. mark than the diazotised *m*-aminoazotoluene. Bismarck Brown and diazotised meta-aminoazotoluene gave a fine orange-brown.

All these shades can be discharged by means of hydrosulphites, but the white is not always perfect. The best results are usually obtained on the shades developed with *p*-nitraniline.—A. B. S.

Logwood Black suitable for Printing on Tissues prepared with β -Naphthol. P. P. Wicktoroff. Bull. Soc. Ind. Mulhouse, 1905, 75, 49—51.

PRINTING mixtures were prepared from logwood extract oxidised by (i.) sodium chlorate and potassium cyanide, to which, after thickening with starch, ferrous sulphate or ferric chloride was added; and by (ii.) sodium bichromate, the precipitate formed being dissolved by heating with hydrochloric acid (in the ratio of one part of the concentrated solution to seven parts of the precipitate) and the solution obtained, after thickening, being printed alone and also with the addition of ferric chloride. Blacks produced were, however, inferior to one from a mixture of logwood extract (at 30° B.—45 parts) and acetic acid (at 6° B.—23 parts), potassium sulphite solution at 45° B.—15 parts) and ferrous sulphate (10 parts), which was heated and cooled; 10 parts of mixture being diluted with five parts of water and thickened by means of 15 parts of gum-tragacanth.

Frey states that the last described mixture gives satisfactory black without steaming, thus dispensing with the passage through the Mather-Platt steaming apparatus, usual for Logwood Blacks printed in association with Paranitraniline Red upon tissues prepared with sodium β -naphtholate, an operation which injures the shade of the red.—E. B.

Printing with Direct Dyestuffs. P. Wilhelm. Bull. Soc. Ind. Mulhouse, 1905, 75, 46—47.

WHEN a thickened solution of Congo Blue 2B is printed upon a cotton tissue, and this is steamed with very little steam, the dyestuff becomes more completely fixed; it would have been if ordinary steam had been employed. The same improvement results when hygroscopic substances, such as ammonium thiocyanate, sodium acetate, calcium chloride, and, especially, ammonium nitrate and glycerin, are added to the printing mixture, and steaming is accomplished with ordinary steam.

The author's experiments have been repeated by Groheintz, who states that there is great advantage in adding ammonium nitrate (350 parts at 23° B.) and glycerin (10 parts) to the printing mixtures (composed of 30 parts of dye dissolved by the aid of 10 parts of sodium carbonate, and thickened with 500 parts of gum-tragacanth), in the case of Congo Blue 2B and Diamine Sky Blue. With these, the colours obtained, after steaming in the usual manner and soaping at 50° C. for 15 minutes, are twice as intense as those produced without the aid of the hygroscopic substances. The unprinted parts of the tissues are also much clearer. The action does not, however, seem to be general with the direct dyestuffs. In the case of a number tried, little or no difference in the intensity of the colours fixed, was observable. Among some, namely, Diamine Black, Diamine Green, Oxal Blue, Mikado Orange and Diamine Violet the fastest soaping was slightly increased; with others, such as Diamine Fast Red and Diamine Scarlet B, it was diminished. Ammonium chloride, magnesium chloride, glucose, sodium acetate, and other compounds, added in place of the mixture of glycerin and ammonium nitrate, to the printing mixture containing Diamine Sky Blue, gave results inferior to those obtained with the latter mixture. The difference in intensity between the shades produced with moist and dry steam respectively is, according to Groheintz, slight, but is in favour of the former.—E. B.

ENGLISH PATENTS.

Silk; Manufacture of Artificial — from Solution of Cellulose [Application of Mercerising]. R. Linkmeier, Herford, Germany, and M. Pollak, Paris, France. Pat. 1501, Jan. 25, 1905.

A CUPRO-AMMONIACAL solution of cellulose is passed in the manner usual in the manufacture of artificial silk.

with minute apertures, into a bath of an acid diluted to a degree as to be incapable of instantly combining with the salts of the cupric solution," e.g., a 1-2 per cent. solution of sulphuric acid. The threads thus obtained when caused to enter a bath of caustic soda or caustic potash at 10° – 40° B. After being rinsed in water, they are treated with acid, and are then washed and dried. The threads produced are, it is declared, more numerous than those which have been passed, after their treatment, through acid or neutral baths only. (See *Fr. Pat.* 347,960, this J., 1905, 438.)—E. B.

Wool; Manufacture of Lustrous Threads of —. Linkmeyer, Herford, Germany. Eng. Pat. 4761, March 7, 1905. Under Int. Conv., Aug. 26, 1904.

Sulphuric acid "in a highly concentrated state" has been previously employed in the manufacture of threads from cupro-ammoniacal solution of cellulose, owing to a decomposition of the threads which occurs when these are freed from the draw-plates in the sulphuric acid. The decomposition appears to be due to the fact that free ammonia is liberated when cellulose is dissolved in the ammonium solution, and the present invention is based upon the theory that the decomposition of threads by the dilute sulphuric acid does not take place when the liberation of ammonia in the cellulose solution has been previously prevented by the action of a vacuum or the injection of air. Hence the present invention consists in precipitating threads of a "dilute" acid, e.g., sulphuric acid of 20 per cent. strength, the cellulose from a cupro-ammoniacal solution deprived of combined ammonia as described. The threads thus obtained, which do not break during weaving, and which may be rapidly drawn out, become very fine. In addition to the advantage gained by the use of the more dilute acid, the process permits of the ready recovery of a large proportion of the ammonia employed. (See this J., 1905, 238.)—E. B.

Woolen Fabrics; Process and Means for Washing —. Kellner, Vienna. Eng. Pat. 10,272, May 4, 1904.

Woolen fabrics are "washed or cleansed" by means of a solution of an alkali hypochlorite and an alkali hydroxide, which is applied in dilute solution. Oils or fats, resins, especially colophony resin, turpentine and "scenting substances," may be added to the solution.—E. B.

Wool; Detergent for Scouring —. S. Wohle, London. Eng. Pat. 12,632, June 3, 1904.

The detergent in question is composed of a vegetable alkali, prepared from linseed, and saponin. An oil, such as castor oil, an acid or acid salt, and in small proportion, a soluble peroxide, may be admixed with it. In its use, it is stated, the wool-grease is removed from the wool without being saponified, and is, therefore, easily recovered. Moreover, the wool is left in a more flexible condition than it is by ordinary scouring processes and requires less oil to be mixed with it to adapt it for spinning.—E. B.

Washing Liquor; Apparatus for [Electrolytic] Preparation of —. F. L. Bartelt. Eng. Pat. 16,185, July 21, 1904. XI. A., page 678.

Cloth and the like; Cylinders for Shrinking and Stretching —. B. Gerlach, Grimnitzsch, Germany. Eng. Pat. 7005, April 3, 1905.

Inside the rotating cylinder employed in the operation of shrinking cloth, is arranged an elastic support upon which is fixed a scraper which, by pressing against the inner side of the cylinder, removes steam bubbles and water drops, formed during the operation, the water being received in a trough placed below the axis of the cylinder, and thence conducted to exit pipes at the ends of the cylinder.—E. B.

FRENCH PATENTS.

Wool; Apparatus for Scouring —. P. Basin, Fr. Pat. 349,243, Nov. 28, 1904.

A CYLINDER A (see Figs.) with openings *c* in it, parallel to its axis, has within it a system of rakes or forks B, borne by frames E, upon a number of shafts F, which project outside the cylinder. An arm G carrying a friction-roller *d* is mounted upon each of the shafts F. These rollers

FIG 1.

FIG 2.

follow the curved guide-plates H and K, outside the cylinder, their movement away from, or nearer to, the axis of the cylinder causing the forks to project out of, or to enter the cylinder. The wool L received in the washing or scouring tank is seized by the forks, carried forward by them as they move with the cylinder, and then released at the point where the prongs of the forks are withdrawn into the cylinder.

In an alternative arrangement, fixed forks are employed. Portions of the surface of the cylinder are, in this case, constructed so as to be movable away from or towards the axis of the cylinder, their movement causing the forks to be either hidden or exposed as the case may be.—E. B.

Plants; Preparing Dried — for Bleaching and Dyeing. Seibt and Becker. Fr. Pat. 349,323, Dec. 21, 1904.

To adapt them for bleaching and dyeing, dried plants and

flowers are immersed in warm alcohol in which is suspended or dissolved either an alkali hydroxide, carbonate, or soap. After being washed in water, they are ready for bleaching or dyeing, these operations being accomplished in the usual manner.—E. B.

Hydro-sulphite Compounds [with Ketones]; Process for Manufacturing Stable —. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 349,235, March 14, 1904.

SEE Eng. Pat. 6214 of 1904; this J., 1905, 194.—T. F. B.

Discharges [Tissue Printing]; Producing — by means of Hydrosulphites. See Badische Anilin und Soda Fabrik. Third Addition, dated Nov. 23, 1904, to Fr. Pat. 297,370 of Feb. 19, 1900 (under Int. Conv., Oct. 24, 1904).

It has previously been discovered (this J., 1905, 87 and 130) that the keeping properties of printing-mixtures containing hydrosulphites (this J., 1900, 900; 1901, 43; 1904, 900; 1905, 333) are improved by the addition to these of either caustic alkalis or soluble salts, in sufficient quantity to prevent, to at least a considerable extent, the solution of the hydrosulphites. It is now found that a similar improvement results, but in a greater degree, when water is excluded, as far as possible, from the mixtures and its place is taken by a suitable organic liquid, such as glycerin. A thickening is prepared by heating together, for example, starch (300 grms.), dextrin (900), and crude glycerin (4800). With this, discharge printing-mixtures are made (a) by adding (to 400 grms. of the thickening) the double hydrosulphite of sodium and zinc (420 grms.) and crude glycerin (180 grms.), or (b) by mixing with it (440 grms.) caustic soda-lye (110 grms. at 45° B) and sodium hydrosulphite (300 grms.), stirred or ground into a paste with glycerin (150 grms.). The tissues printed with these mixtures are dried, steamed (for three minutes in the case of mixture (a); for four minutes in that of (b)), and are then washed and soaped as usual.—E. B.

Printing with Indanthrene and Flavanthrene; Process of —. Farbwerke vorm. Meister, Lucius und Brüning. Fr. Pat. 349,376, March 21, 1904.

SEE Eng. Pat. 6848 of 1904; this J., 1905, 194.—T. F. B.

Calender; Double-acting — for Hot-pressing Tissues either Once on each side, or Twice on One Side. V. Cochetoux. Fr. Pat. 349,310, Dec. 20, 1904.

THE apparatus claimed, consists essentially of two cylinders mounted one above the other, round each of which an endless felt band is stretched. A curved metal plate is placed immediately beneath each of the cylinders. The tissues to be finished, after being passed at full width in contact with the felt band, between the bottom cylinder and plate, are drawn to the upper part of the apparatus and, according as they are to be operated upon again on the same or on the opposite side, are passed, either in the same direction as before or in the opposite direction, between the upper cylinder and plate.—E. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

ENGLISH PATENT.

Designs or the like in Atomised Colours; Apparatus for Applying — to Paper or other Material. E. Marinier, Paris. Eng. Pat. 14,362, June 25, 1904.

SEE Fr. Pat. 342,484 of 1904; this J., 1904, 982.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Nitrogen Oxides and Nitric Acid; Preparation of — from Compressed Air by the Electrical Method. E. Rossi. Gaz. chim. ital., 1905, 35, 89–110. Chem. Centr., 1905, 1, 1525–1526.

THE author determined the amounts of nitric oxide or

nitrogen peroxide formed from air, by the aid of the Nernst electric lamp, under varying conditions. The experiment was conducted over the Nernst electrodes in varying quantities and at different speeds, the amount of nitric oxide formed being determined with Lunge's nitrometer. It was found that the yield of nitric oxide increased rapidly with increase of current-strength; under similar conditions, a current of 0.25 ampère gave no nitric oxide, gave 3 with 0.25 ampère, and 6.5 e.c. of nitric oxide with 2.8 ampère. In equal periods of time, the same yield of oxide was obtained from 5 litres of air, from 10 litres of air passed through the apparatus at twice the speed from 1 litre of air at rest, when the nitric oxide absorbed as it was formed. The yield of nitrogen is proportional to the pressure of the gas. With one ampère and a current-strength of 1 ampère, 100 e.c. of nitric oxide were obtained in 3½ hours from 5.2 litres of air under a pressure of 100 atmospheres. The utilisation of the energy of the lamp was, however, very poor with quiet air. By introducing concentrated sulphuric acid in the lamp to absorb the oxides as they were formed, the yield was increased to 35 per cent. in 2 ampère hours from 5 litres of air under a pressure of 50 atmospheres. The velocity of the reaction decreases with the time, owing to the air becoming deficient in oxygen. At a pressure of 90 atmospheres, the reaction proceeded much more rapidly at first, but subsequently more slowly than at a pressure of 50 atmospheres.—A. S.

Ammonia; Direct Synthesis of —. E. P. Reclus. Roy. Soc. Proc., 1905, A, 76, 167–174.

THE author's experiments prove that ammonia can be synthesised from nitrogen and hydrogen by the action of heat alone; the decomposition of ammonia by heat at 800°–1100° C. is, therefore, irreversible. Synthesis can be accomplished (in small quantities) when the gas is partially ionised, as by sparking them, or by exposing them with oxygen, or by heating them with many metals in the presence of moisture. In the latter case it does not appear that nitrides are intermediate products, since nitride-forming metals such as magnesium are not more effective than others.—W. A. C.

Sodium Alum; Notes on —. J. M. Wadmore. Soc. Proc., 1905, 21, 150.

ZELLNER in 1816 stated that he had prepared this alum, but its existence has been denied by Ostwald. By mixing together solutions of suitable quantities of sodium sulphate and aluminium sulphate, a substance was obtained crystallising in octahedra, and having a composition corresponding to the formula $\text{Na}_2\text{SO}_4 \cdot \text{Al}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$. 1 gm. of water at 10.6° C. dissolves 1.071 gm. of the crystalline salt. When a hot concentrated solution of the salt is cooled, a pasty or oily substance is deposited, which is slowly transformed into the crystalline sodium alum. Sodium alum does not effloresce appreciably at the ordinary temperature. It loses rapidly about one-half of its water of crystallisation at 50° C.—A. S.

Hydrogen Sulphide and Sulphur Dioxide; Interaction of —. W. R. Lang and C. M. Carson. Chem. Soc. Proc., 1905, 21, 158–160.

WACKENRODER'S reaction, obtained by passing hydrogen sulphide into an aqueous solution of sulphur dioxide for several periods of from two to three hours on successive days, has been found by Debus (Chem. Soc. Trans., 1888, 53, 278) to contain sulphur, and sulphuric, trithionie, tetrathionie, and pentathionie acids, and probably also hexathionie acid. The authors have investigated the reaction in presence of only a small quantity of water, hydrogen sulphide and sulphur dioxide being passed, at about equal rates, for 2–3 hours, in a large flask surrounded with snow and containing a small amount of moisture. A heavy yellow deposit was obtained which lost from 25 to 35 per cent. by weight on heating to 100° C. for one hour, the residue then containing over 96 per cent. of free sulphur. The amount of sulphur compound (estimated as sulphuric acid) in the deposit never exceeded 1 per cent. The deposit when kept in stoppered bottles at the ordinary temperature, became pliable and elastic, and covered with an oily liquid of acid reaction, whilst

time time, sulphur dioxide was evolved. The only had a sp. gr. usually above 1.35, and corresponded the ordinary "pentathionic acid," or, as Debus d it to be, a mixture of polythionic acids. The reaction between gaseous hydrogen sulphide and or dioxide thus appears to be that represented by $2\text{H}_2\text{S} + \text{SO}_2 = 3\text{S} + 2\text{H}_2\text{O}$, the sulphur and slowly interacting at relatively higher temperatures polythionic acids.—A. S.

Antimony Sulphide; Fusibility of Mixtures of —, with Cuprous Sulphide and Mercuric Sulphide. H. Pelabon. *Comptes rend.*, 1905, 140, 1389—1392.

Mixtures of cuprous sulphide to antimony sulphide the melting-point till the proportion of cuprous de is 0.11 of the whole (498°C .); further addition it. This eutectic corresponds nearly to the com- $4\text{Sb}_2\text{S}_3 \cdot \text{Cu}_2\text{S}$. Mixtures containing more than to Sb_2S_3 show two points on cooling, incipient eation, a temperature rising with increase of cuprous de, and complete solidification, always close to 70°C ., as long as the cuprous sulphide does not overstep proportion $10\text{Cu}_2\text{S} : \text{Sb}_2\text{S}_3$. For the mixture Sb_2S_3 these two points coalesce at 570°C . These res show a strong tendency to superfusion, and in cases no separation of the mixture of higher fusing occurs till the temperature has fallen to the solidi- point of the other mixture: when the latter begins arate, separation of the former is induced, and the rature rises again.

Mercuric sulphide behaves similarly to cuprous sulphide: tectic contains 34 per cent. of mercuric sulphide and at 455°C . Mixtures containing more mercuric sulphide this loss it rapidly by volatilisation at their melting , which are consequently difficult to determine tely. At the atmospheric pressure no mixture ning more than $3\text{HgS} : \text{Sb}_2\text{S}_3$ can be melted, the loss latilisation is so rapid.—J. T. D.

Phosphorus; Solubility of —, in Ether and in Benzene. C. Christomanos. *Z. anorg. Chem.*, 1905, 45, —141.

DETERMINATION of a weighed quantity (in excess) of phos- s with definite quantities of the solvents, and nation of the weight of phosphorus remaining, as aporation of a known weight of a saturated solution etermination of the weight of residual phosphorus, ly approximate and not closely concordant results, because of the volatility of the phosphorus. The esults were obtained by oxidation of the phosphorus eighed quantity of the solution by means of cupric e, bromine, and nitric acid (this J., 1904, 1000). etermination of the phosphoric acid produced. ing-point determinations confirmed very closely the s so obtained. The amounts dissolved by 100 grms. er were:—At 0°C ., 0.4335 grm.; and at 35°C ., of solvent) 1.9984 grms. The corresponding figures e case of benzene were:—At 0°C ., 1.513 grms.; t 81°C ., 10.027 grms. In each case the rise of ility was throughout closely proportional to the ent of temperature. Both solutions are colourless fresh, but turn yellow after a time, the ether solution so, and more rapidly, than the benzene solution. es for the densities and refractive indices of the ons at various temperatures are given. On evapora- the ether solution yields regular octahedra, the ne solution long prisms or columns, from which diary crystals branch off at right angles in frond-like on.—J. T. D.

ENGLISH PATENT

Hydrosulphites; Manufacture of Soda —. J. V. Johnson, London. From the *Fabrik der Sodafabrik, Ludwigshafen-on-Rhine, Germany*. Eng. Pat. 8816, April 26, 1905.

INSTEAD of immediately separating the hydrosulphite precipitated from its hot solution by sodium chloride, as prescribed in Eng. Pat. 19,762 of 1899 (this J., 1900, 700), it is now directed to continue the heating for some time after the precipitation, whereby the hydrosulphite is obtained free from water of crystallisation, in the form of a heavy, sand-like and stable powder. According to one example, the hydrosulphite, precipitated in the usual way, and containing water of crystallisation, is, after removal of most of the supernatant liquid, heated with the mother liquor to from 50° to 70°C ., and sodium chloride is added to saturation. The stirring is continued for half-an-hour, the temperature being maintained as before, and the product is filtered hot, washed with alcohol, and dried in a vacuum. Such salts as sodium sulphate, carbonate, nitrate or acetate, may replace sodium chloride for precipitating the hydrosulphite. (Compare Eng. Pats. 901 and 18,852 of 1900 (this J., 1901, 43 and 988); 2204 of 1903 (this J., 1903, 1347), and 7397 of 1904 (this J., 1905, 132); also Fr. Pats. 336,942 of 1903; 341,718 of 1904, and First and Second Additions to the same, this J., 1903, 442; 1904, 900; and 1905, 333.)—E. S.

UNITED STATES PATENT.

Oxygen from Hypochlorites; Production of —. G. F. Jaubert, Paris. U.S. Pat. 790,504, May 23, 1905.

VIII.—GLASS, POTTERY, AND ENAMELS.

ENGLISH PATENT.

Glass; Manufacture of Silica [Quartz] —. J. F. Bottomley, Wallsend; R. S. Hutton, Manchester; and A. Paget, North Cray. Eng. Pat. 10,670, May 9, 1904.

SILICA glass is made by heating sand either by conduction or radiation, or both, from material such as carbon or graphite, shaped so as to give the desired heating area, and heated by the passage of an electric current, the plastic product obtained, being shaped *in situ* either by blowing it by means of a gas introduced in any convenient way, or else by pressing it between dies. The heating may be carried out either by passing a current through a resistance core of homogeneous material around which the sand is packed, or by passing the current through the walls of a vessel containing the sand. The latter may be directly in contact with the resistance material, or may be protected from it. The gas may be introduced by hollowing out the resistance material or by an independent carbon tube. When dies are used to shape the plastic mass, the material may be heated by a plate above and out of contact with it, which plate is removed when the silica has become plastic, the dies then being introduced.—A. G. L.

UNITED STATES PATENTS.

Insulators; Method of Manufacturing High-Potential Earthenware —. F. M. Locke, Victor, N.Y. U.S. Pat. 790,214, May 16, 1905.

A DENSE, homogeneous, plastic mass, practically free from impurities, is formed by triturating and levigating the raw material such as kaolin, with water, and expelling nearly the whole of the moisture from the mixture. The plastic mass is then mechanically shaped under a uniformly and gradually increasing pressure, compressed air being introduced against the surface of the mass, whilst the maximum mechanical pressure is being applied. The ware is finally glazed and fired.

—A. S.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Brick, Hardening Lime Sand — E. Cramer. *Tonind. Zeit.*, 1905, 29, 558—560.

EXPERIMENTS were made with a fine and fairly pure sand, containing 83.5 per cent. of grains between 0.1 and 0.6 mm. diameter and weighing 1.781 kilos. per litre when shaken down in the measure. With this sand two mixtures were made: one containing 4 per cent. of the other 6 per cent. of dry-slaked Harz lime, one portion of each being mixed by 15 revs. of the Steinbuck edge-runner mill, the other by 30 revs. All the mixtures contained 3 per cent. of water. A portion of each was pressed into cubes of 30 sq. cm. face, at once, the rest being stored 24 hours before pressing. The pressures employed were 150 and 250 kilos. per sq. cm. respectively, and the blocks were hardened by steaming for nine hours, some at 6 atmos., the rest at 9 atmos. pressure. The results, referred to the number of revolutions employed in mixing, indicated that 15 revs. produced a sufficiently homogeneous mixture. The steaming for 24 hours had practically no influence on the tensile strength, while the higher pressure used in moulding the cubes had an adverse effect in nearly every case. On the other hand the strength was greater in the cubes hardened under a steam pressure of 9 atmos. than in those treated at 6 atmos., a typical increase being from 59.8 kilos. per sq. cm. to 147.6 kilos. with 4 per cent. of lime, and from 119.8 to 177.0 kilos. with 6 per cent. of lime. A comparison of these figures also shows that whilst the higher proportion of lime gives a stronger brick, the increase is not comparable with that obtainable by the use of a higher steam pressure in hardening.—C. S.

ENGLISH PATENTS.

Stone; Manufacture of Artificial — for Paving, Decorative and other purposes. N. G. H. von Kaufmann and C. E. H. Medberg, both of Gothenburg, Sweden. Eng. Pat. 11,830, May 24, 1904.

THREE separate mixtures are made: (1) Slate powder (55 to 80 parts) is mixed with five parts of sulphite-cellulose and five parts of blue clay and enough alum solution to give a plastic mass. (2) Zinc oxide (two parts) is mixed with one part of aluminium sulphate and one part of burnt magnesite. (3) Hydraulic lime (six parts) is mixed with 10 parts of calcium chloride and a sufficient quantity of potassium sulphite solution.

A mass of suitable consistence is prepared from these three mixtures, together with a weak solution of sodium or potassium phosphate; coarsely ground and well-dried slate is then added, the whole filled into moulds, which have been previously sprayed with chalk or similar powder under a pressure of about 2,000 atmospheres. After removal from the moulds, the stones are placed in a hardening liquid consisting of equal parts of potassium silicate, sulphuric acid, and saltpetre, at a temperature of 18° C. The stones are finally rinsed with warm water and dried.—A. G. L.

Granite; Artificial —, and *Process for the Manufacture of the same*. H. Vokes, Kingston-upon-Hull. Eng. Pat. 12,940, June 8, 1904.

GRANITE or marble chips, or a mixture of both ($2\frac{1}{2}$ stones weight), are mixed with cement, preferably Portland cement ($\frac{3}{4}$ stone), granite or marble dust ($2\frac{1}{2}$ stones) and a suitable colouring matter ($5\frac{1}{2}$ lb.). Enough water is added to give a plastic mixture, which is placed in moulds. After about five days, when sufficiently set, the blocks are removed from the moulds, and immersed in water for four days, after which they are allowed to harden in a warm, shady place, and finally polished.—A. G. L.

Stone, Artificial Plaster, or Plastic Material; Manufacture of —. S. Elmes, West Ealing. Eng. Pat. 17,879, Aug. 17, 1904.

ALABASTER plaster, Keene's or Farian cement, is mixed

with an equal quantity of powdered natural stone, a small percentage of borax or alum being added to harden material. Saffron, or other fast dye, is then added well as washed sand, if desired. A little glue may be added; in this case formaldehyde may be substituted for the borax or alum. The mixed powder is gauged with water and applied directly to the laths, &c., or else it may be moulded into bricks or slabs. The surface may be covered with a coating of glue, with or without the application of a hardening agent such as alum, borax or formaldehyde.—A. G. L.

Bricks, Tiles, and the like; Manufacture of —. E. Trapnell and R. L. Wood, both of Cheltenham. J. Pat. 28,368, Dec. 27, 1904.

CLAYS or shales, which have different colours after burning, are mixed together and worked in a semi-plastic state so as to give bricks or tiles of mottled appearance when finished.—A. G. L.

UNITED STATES PATENT.

Gypsum Mortar; Method of Improving — and *Utilising Dead-burnt Gypsum*. K. Heintzel, Lüneburg. U.S. Pat. 790,366, May 23, 1905. SEE FR. Pat. 349,260 of 1904; following this.—T. F.

FRENCH PATENT.

Plaster for Cast Plaster Floors; Method of Improving and of Utilising Over-burned Plaster. C. Heintzel and E. Cramer. Fr. Pat. 349,260, Dec. 20, 1904.

THE low initial hardening power of ordinary plaster for cast-plaster flooring, militates against its use for ceilings, blocks, and as a building mortar. This may, however, be improved by an addition of $\frac{1}{2}$ per cent. of potassium or sodium bisulphate, either before or during the mixing of the plaster for use. The tensile strength of the plaster (containing 20 per cent. of water) is usually 1 kilo. per sq. cm., at the end of one day after mixing, rising to 11 kilos. by the end of 28 days, whereas with the addition of $\frac{1}{2}$ per cent. of potassium bisulphate the corresponding values are raised to five and 32 kilos. per sq. cm. respectively. Analogous results are obtained by treating over-burned plaster in the same way.—B.

X.—METALLURGY.

Iron Sulphides and the Purification of Coal Gas by means of Ferric Hydroxide. L. Gedel. J. f. Gasbel, 15, 48, 412—417; 428—432. (SEE also under page 664).

I. Iron Sulphides formed by Dry Methods.—By heating pure iron powder with excess of sulphur till that excess is distilled off, Rammelsberg (Pogg. Ann. 121, 7) stated that ferric sulphide, Fe_2S_3 , is formed. Berzeliuss (Lehrbuch der Chem. 4 Aufl. 3, 437) and the author, on the contrary, have proved that ferric sulphide is not formed pyrogenetically, and the author shows that from 450°—500° C. iron disulphide is produced, and this at about 700° C., yields the magnetic sulphide, Fe_3S_4 , with expulsion of sulphur and formation of a mass of grey, metallic appearance and yellow lustre. On treatment with hydrochloric acid, this substance was decomposed, yielding hydrogen sulphide and iron bisulphide, but no free sulphur, the action thus resembling that which would have occurred if the compound had been one of $6\text{FeS} + \text{FeS}_2$. The absence of separate sulphur after the acid treatment was sufficient to prove that no ferric sulphide was present. On strongly igniting the magnetic sulphide, Fe_3S_4 , for a long time, the author obtained the monosulphide with expulsion of sulphur. When iron powder was heated with sulphur in a tube placed in a glass tube to from 450°—500° C., with subsequent further additions of the latter, at first the product was a mass with yellow, metallic lustre, was obtained, indicating

formation of the magnetic sulphide. This, after heating and full saturation with sulphur, at passed into a dark greyish green mass, devoid of etic action and consisting of iron bisulphide.]

ur in Coke and its Effect in the Blast-Furnace. Wuest and F. Woolff. Iron and Steel Inst., May, 1905. [Advance Proofs].

results of experiments in which hydrogen, steam, iron, carbon monoxide and carbon dioxide respectively passed over coke heated to different temperatures. That, contrary to the view generally held, the sulphur in the coke does not reach the level of the tuyères in blast-furnace without undergoing alteration, a large part of it being previously volatilised by the ascending gases.

The greater part of the volatilised sulphur is, however, again absorbed from the gases by the descending gas and is thus carried to the level of the tuyères. Experiments showed that, up to 800° C., the sulphur sorbed from the gases principally by the oxides of iron, but from 800° C. upwards, the lime is the chief agent of the sulphur.—A. S.

Furnace Slags; Experiments on the Fusibility of O. Boudouard. Iron and Steel Inst., May, 1905 [Advance Proof].

the level of this surface within the plane of the triangle gives the isothermal curves of fusibility. By the aid of this diagram it is possible to determine the temperature of fusion of any given calcium-aluminium silicate.

In blast-furnace practice the temperature of formation of a slag is higher than that of its fusion, as the fluxes are added in more or less large pieces, but the two temperatures approach one another the more closely, the more intimate and complete the previous mixing of the materials has been, and an economy of fuel would be realised, if the fluxes were crushed and mixed before being introduced into the blast-furnace with the charge.

The fusing point of silica is 1830° C. The addition of a small quantity (about 10 per cent.) of silica or alumina to lime causes a considerable lowering of the fusing point. The effect of the addition of lime to alumina is not so pronounced; the reduction of the fusing point to 1500° C. is not attained until nearly 40 per cent. of lime have been added. Slags containing from 30 to 90 per cent. of lime have fusing points not above 1500° C. The existence of the following definite compounds, $\text{CaO} \cdot \text{SiO}_2$, $2\text{CaO} \cdot \text{SiO}_2$, $3\text{CaO} \cdot \text{SiO}_2$, $\text{CaO} \cdot \text{Al}_2\text{O}_3$, $2\text{CaO} \cdot \text{Al}_2\text{O}_3$, $3\text{CaO} \cdot \text{Al}_2\text{O}_3$, was proved. In the case of mixtures of lime, alumina and silica, it was found that the addition of alumina to a silicate of calcium first increases the fusibility, which ascends to a maximum, but ultimately reduces it. The

The author has determined the fusibility of calcium and aluminium silicates, calcium aluminates, and double silicates of calcium and aluminium. The results are set in a series of tables and curve-diagrams, and in the accompanying triangular curve-diagram (see Fig.), in which the points on the sides correspond to binary compounds, whilst the composition of each ternary compound corresponds to a point within the triangle, the portion of each constituent being represented by a line drawn from this point parallel to one of the sides. In order to represent the variation of fusibility, lines are drawn from each point in the triangle perpendicular to the base, and of a length proportional to the temperature of fusion of the constituents corresponding with the points which the lines are erected. The loci of these points form the surface of fusibility, whilst the projection of lines from

more basic a silicate is, the greater is the amount of alumina required to render it fusible.

In the case of calcium silicates containing more than 30 per cent. of silica, the substitution of alumina for lime up to 25 per cent. causes a marked increase of fusibility, but with larger proportions of alumina, the fusibility rapidly decreases. With a silicate containing 30 per cent. of silica, the substitution of alumina for lime has little effect until the amount reaches 35 per cent., when the fusibility falls rapidly. For slags with less than 30 per cent. of silica, there is a notable increase in the fusibility up to 50 per cent. of alumina, but beyond this the fusibility diminishes very rapidly.

In the following table the results of the determination of the temperatures of fusion of some industrial slags are given :—

Description of Metal.	Percentage Composition of Slags.								Temper- of Fus
	SiO ₂ .	Al ₂ O ₃ .	CaO.	MnO.	MgO.	FeO.	Alkalis.	CaS.

* In these cases the term "lime" includes all the oxides other than silica and alumina.

Calcium; Metallic ——. K. Arndt. Ber., 1905, 38, 1972—1974.

THE author has examined the characters of three aluminium-calcium alloys supplied to him, containing respectively 25, 50 and 80 per cent. of calcium. The two latter were not homogeneous, the calcium-content varying to the extent of about 4 per cent.

Alloy with 25 per cent. of Calcium.—This had a dull metallic appearance, like cobalt; it was very brittle, with a granular fracture. Sp. gr., 2.12 to 2.18; m. pt., 765° C.

Alloy with 50 per cent. of Calcium.—The alloy resembled nickel in appearance; it was very brittle, with a finely granular fracture. Sp. gr., 2.26 to 2.38; m. pt., 1050° C. From this alloy pure calcium can be separated by distillation in a high vacuum.

Alloy with 80 per cent. of Calcium.—This had a brilliant white fresh surface, rapidly turning yellow and becoming coated with a thick grey layer of oxide. It was not so brittle as the other alloys, and had a crystalline fracture, showing yellow and red tarnish almost immediately. Sp. gr., 1.74 to 1.81; m. pt., 600° C. It readily furnishes pure calcium by distillation in high vacuum.

The high melting-point of the 50 per cent. alloy suggests the existence of a compound.—J. T. D.

Silicon in Iron; Determination of ——. D. F. Morgan. XXIII., page 692.

Gas; Determination of Dust in Blast-Furnace ——. E. Hubendick. XXIII., page 691.

ENGLISH PATENTS.

Projectiles; Manufacture of ——. R. A. Hadfield, Sheffield. Eng. Pat. 15,219, July 7, 1904.

THE projectile, after being subjected to a preliminary heating and annealing process, is gradually and uniformly heated in a furnace to a temperature ranging between 820° C. and 950° C. (or even higher in special cases), and then dipped point downwards to the depth to which it is to be hardened, in oil or in other cooling medium. In the case of a projectile of nickel-chromium steel, it is heated to about 865° C. before partially dipping, as described, in the cooling medium. Projectiles of large calibre may be heated before dipping, to a lower temperature than that mentioned, say to 800° C. The process may also be modified in other respects in certain

described cases. Reference is made to Eng. Pats. 2 (this J., 1897, 49), 27,754, and 27,755, of 1897; to 3543 of 1898; and to 7882 of 1904 (this J., 1905, 14).

Briquettes for Steel-making, Fuel, &c. R. F. St. London. Eng. Pat. 10,066, May 2, 1904.

BRIQUETTES for steel-making are made:—(1) From ore, purple or Spanish, 86 to 88 per cent., lime or calcined earth 4 per cent., pyroligneous tar $7\frac{1}{2}$ to 9 per cent., sodium silicate or the like $\frac{1}{2}$ per cent.; (2) sand or other ores of sharp, gritty material 84 to 86 per cent., lime or other calcined earth 3 to 4 per cent., alumina 3 to 4 per cent., pyroligneous tar $7\frac{1}{2}$ per cent., sodium silicate or the like $\frac{1}{2}$ per cent.; (3) for fuel in blast-furnace, coal 88 per cent., lime 3 or 4 per cent., tar 7 per cent., sodium silicate $\frac{1}{2}$ per cent. Anthracite, bituminous or semi-bituminous coal, lignite, peat, or charcoal may be used, slightly varying the proportions. The ore or coals and the lime (and alumina when used) are ground to powder and thoroughly mixed, then the tar and silicate are added and thoroughly incorporated, finally the mass is compressed into blocks.—J. H. C.

Steel; Hardening High-Speed Tool ——. S. N. Brays. Manchester. Eng. Pat. 12,817, June 7, 1904.

THE steel is heated to a high temperature, quenched in a bath of salt, lead, or other material heated to about 500° C., and finally quenched in water or other liquid.—J. H. C.

Iron Ores and Concentrates; Means for Dephosphorizing ——. W. Simpkin, London, and J. B. Ballantyne, Richmond, Surrey. Eng. Pat. 14,214, June 23, 1904.

THE ores are heated, digested for a few minutes with dilute sulphuric acid, and subsequently washed. The operation is carried out in troughs provided with revolving conveyors.—J. H. C.

Ores; Process of and Apparatus for Refining ——. W. Clark, London. From E. Goldschmidt, Frankfurt-on-Maine, Germany. Eng. Pat. 11,437, May 18, 1904. SEE Fr. Pat. 343,313 of 1904; this J., 1904, 1032.—T. J. B.

Simultaneous Concentration of the Matte. N.
 eff, St. Petersburg. Eng. Pat. 14,980, July 4,

Pat. 344,530 of 1904; this J., 1904, 1095.—T. F. B.

UNITED STATES PATENTS.

Steel. R. A. Hadfield, Sheffield.
 U.S. Pat. 786,561, April 4, 1905.

made for a steel containing from about 0.3 to
 cent. of carbon, up to 0.25 or 0.3 per cent. of
 manganese, 2—5 per cent. of nickel, and 1—3 per cent.
 of molybdenum. The steel is stated to possess a high elastic
 tenacity, with great ductility and toughness.
 —A. S.

Furnace [Mercury —]. A. Skoog, Shreveport,
 Louisiana. U.S. Pat. 783,903, Feb. 28, 1905.

The furnace is shown in cross-section through the
 middle of the furnace in Fig. 1, and in section in

Fig. 1.

It consists (Fig. 1) of vertical fire-chambers
 and ore-chambers 3, arranged alternately, with fire-
 on two opposite sides of the furnace at right
 to the chambers 2, 3. The heat and gases from
 the boxes pass through openings into the ends of
 chambers 2, which have each a transverse partition
 a third of the way up, so that the fire-gases are
 pass first through the openings 7 into the ore-
 chambers, through the body of ore, and subsequently
 through the openings 8 into the fire-chambers above
 positions 6. At about two-thirds of the height of
 the chambers, baffles 9, 10 are provided, between
 and which the gases and mercury vapour pass
 the upper compartments of the fire-chambers, then
 through the openings 12 into the dust chamber 13,
 and finally through the pipe 14 to the condensers.
 Chambers are provided to about two-thirds of
 height with the usual inclined tiling 18, but the
 ends of the tiles of the outermost row do not extend
 to the walls of the ore-chambers. The space 19 in the
 part of each ore-chamber, corresponding to the
 compartments of the fire-chambers is left untiled,
 and is used as a drying chamber for the ore. Wet ore is

fed into the ore-chambers through the opening 15 (Fig. 1),
 and is dried in the chambers 19 (Fig. 2) before passing
 to the tiled compartments of the ore-chambers, where
 the mercury is distilled off. The roasted ore is discharged
 through the openings 16 (Fig. 1).—A. S.

Furnace; Smelting —. C. E. Glafke, Los Angeles,
 Cal. U.S. Pat. 790,825, May 23, 1905.

THE furnace consists of an inclined cylindrical rotating
 smelting-chamber mounted on a frame-work, and having
 both ends partially closed. The ore is fed in at the upper
 end of the chamber, into which also projects a hydro-
 carbon burner for heating the furnace. A baffle is arranged
 near the lower end of the smelting-chamber, which com-
 municates with a stack.—A. S.

Leaching Apparatus [Ores]. C. E. Dewey, Denver, Cal.
 Assignor to American Zinc and Chemical Co., Denver.
 U.S. Pat. 787,902, April 25, 1905.

FOR leaching ore-pulp with chemicals introduced from
 below, a leaching vat of V-shaped cross-section is provided,
 together with a lead pipe extending the whole length of
 the bottom of the vat. The lead pipe serves for the
 introduction of the acids, &c., and is provided with a
 series of nozzles adapted to direct the liquid vertically
 upwards. These nozzles are formed by moulding solid
 projections in a straight line along the outer wall of the
 pipe, and by fixing orificed nozzles of porcelain to the
 tops of the projections, subsequently boring the lead so
 as to extend the orifice to the interior of the pipe.—J. F. B.

Copper; Method of Recovering — from its Ores.
 H. M. Wilcox. Assignor to Esmeralda Copper Pre-
 cipitating Co., Chicago, Ill. U.S. Pat. 790,238, May 16,
 1905.

THE ore is leached with a suitable reagent to convert the
 copper into copper sulphate, air is blown through the
 solution to remove iron and other impurities, and sulphur
 dioxide is then passed in, practically to the point of
 saturation. The solution is then subjected to heat and
 pressure in a closed vessel only partially filled, whereby
 the copper is deposited as metal, the sulphur dioxide
 "escaping from the liquid into the confined space, to
 perfect the reaction."—A. S.

*Metals and Oxides; Process of Recovering — from
 Solutions.* A. Gutensohn, Southend, Essex. U.S. Pat.
 790,429, May 23, 1905.

*Steel; Process of Reduction applied to the Manufacture
 of —*. J. de Moya. Fr. Pat. 349,233, March 14, 1904.

A MIXTURE of 50 per cent. of sodium chloride, 25 per cent.
 of sodium bicarbonate, and 25 per cent. of saltpetre, is
 added to the molten metal in the proportion of 2 kilos.
 per ton of metal, and subsequently about 3 kilos. of calcium
 chloride are added. The additions may be made up into
 packets either separately or together. Finally, packets
 containing about 5 kilos. of very finely-divided "Carmoya"
 (a carboniferous mineral) are added from time to time
 to recarburise the metal.—J. H. C.

[Alloy] A New Metal, "Parisis." A. Chassereau. Fr.
 Pat. 349,343, March 19, 1904.

THE alloy is prepared from 200 parts of mispickel ($\text{FeAs}_2 + \text{FeS}_2$) 85 parts of $\text{Ni}_3\text{As} + 8\text{As}$, and 715 parts of aluminium.
 These are melted in separate crucibles, and subsequently
 mixed in presence of an alkaline salt and a borate, and
 the mixture is submitted to the action of "carbon dioxide
 gas to remove oxygen"; it is then refined by means of
 silicon or a silicate. For some purposes arsenic is used
 in place of aluminium.—J. H. C.

Air for Blast-Furnaces; Process for Drying —. Soc.
 F. Grimault, Le Soufaché et Felix. Fr. Pat. 349,219,
 Dec. 20, 1904.

THE blast before passing through the stoves or heating

apparatus, is caused to bubble through a solution of calcium chloride, which is contained in a closed vessel and kept at a temperature of about -12°C .—W. H. C.

Steel of Special Hardness; Process for the Production of —. F. Münter. Ger. Pat. 157,881, March 15, 1902.

THE molten steel is subjected to the action of a blast of pure nitrogen.—A. S.

[Iron] Wire, Hoop-Iron, &c.; Process for Hardening —. H. Krautschneider. Ger. Pat. 157,683, Nov. 13, 1902.

THE metal objects to be hardened are placed in a suitable carburising bath, and are heated by passing an electric current through them. They are then quenched by immersion in a cooling liquid.—A. S.

Casting-Moulds; Process for the Preparation of a Coating Composition for —, with Utilisation of Ash [from the Blast-heating Apparatus]. F. Graus. Ger. Pat. 158,258, Oct. 25, 1903.

IN order to prevent "burning-on" of the sand to the molten metal, the moulds are coated with a composition prepared by vigorously stirring $\frac{1}{2}$ kilo. of dextrin with 6 litres of boiling water, and adding to the mixture sufficient of the fine ash which collects in the blast-heating apparatus to give a mass of the consistence of paint.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A.)—ELECTRO-CHEMISTRY.

Electrode Temperature; Relation between Electrolytic Processes and the —. W. Moldenhauer. Z. Elektrochem., 1905. 11. 307–330.

IN accordance with the reasoning of Ostwald, the author considers the heat changes at the electrodes as the sum of the heat of ionisation, and that due to the fall of potential between electrode and electrolyte. The temperature of the electrode was measured by using a hollow electrode in which a thermometer was placed. Various preparations were carried out to study the effect of cooling the electrode upon the yield of product. In the case of persulphuric acid, ammonium persulphate and potassium percarbonate, a considerable improvement was noticeable. Potassium chloride gave better yields of hypochlorite with cooled, better yields of chlorate with heated electrodes.—R. S. H.

Bleaching Liquor; Apparatus for [Electrolytic] Preparation of —. F. L. Bartelt, Bristol. Eng. Pat. 16,185, July 21, 1904.

A PORTABLE apparatus for preparing bleaching liquor for use in steam laundries, or in small bleach works, comprises a platform carrying a solution tank charged with the electrolyte (sodium chloride solution for instance), and also carrying the source of electricity. Below the platform is a storage chamber, and to one side, below the level of

the electrolyte tank, is a relatively small "electrolytic" tank, in which are the electrodes, and below which is a larger tank to receive the bleaching liquor as it is produced in the electrolyser. The electrolyte flows from the solution tank through a pipe provided with a tap into the electrolyser. A bell circuit and a switch circuit are connected to a float in the solution tank, so that when the level of the solution in this tank falls below a certain point the bell rings, and at the same time the supply of current to the electrolyser is cut off.—E. S.

Absorbing Gases by a Liquid under the Action of a Silent Electric Discharge; Apparatus for —. Hemptinne. Eng. Pat. 7101, April 4, 1905. I., page 13.

Gum Resins; [Electrical] Treatment of — and Resulting Product [Sylvine]. A. Nodon. Addition, dated March 1, 1904. to Fr. Pat. 348,653, Feb. 16, 1904. XIII., page 682.

and Mixtures of Gases; Process and Apparatus for the Treatment of —, by the Electric Arc. A. J. J. J. Fr. Pat. 349,227, Dec. 20, 1904.

Subject of the invention is to submit to the action of the electric arc as great a number of molecules of gas as possible. This is attained by displacing the arc continuously across the gases by means of electro-dynamic forces produced by the principal current forming the arc, secondary currents arranged so that the force which the arc is always proportioned to the principal current. The currents traversing the electrodes compel the arc to displace itself along the length of the electrodes, the arc may be in the form of upright parallel rods, one within another, or a spiral electrode may be placed within a cylindrical electrode, these being in each case placed along the length of the chamber through which the gases pass, and the electrodes are brought near each other at the entrance of the chamber to facilitate the formation of the arc.—B. N.

GERMAN PATENTS.

Vapours, and the like; Process and Apparatus for the Treatment of — to the Electric Discharge. Westdeutsche Gas- und Wasserwerke, G.m.b.H. Ger. Pat. 157,629, Dec. 10, 1904.

A rotating drum of insulating material is wound with a conducting wire, which is connected with one end of the source of current. A strip of metal is placed along the axis of and some distance away from the drum, connected with the other pole of the source of current, and an injector or series of injectors is placed to discharge into the space between the metal strip and the drum. When the current is passing, a spark travels through the gas issuing from the injector, the metal strip and the nearest point of the wire. As the drum revolves, the spark travels along the length of the drum as different portions of the spiral wire pass the metal strip. If the speed of rotation of the drum be increased sufficiently, the sparks follow each other so quickly, that practically a continuous electric flame is formed between the drum and the strip.—A. S.

Content of Vapours, Air or Gases; [Electrical] Process for the Determination of the —. R. Schmidt & Döhne. Ger. Pat. 158,105, April 21, 1903.

The moisture content of vapour, air or gases is estimated by measuring the dielectric coefficient of the vapour, &c., by varying the capacity of an electrical condenser placed in contact with the vapour, &c., with that of one or several condensers in contact with the vapour, &c. The condenser placed in contact with the vapour, &c., is connected with electrical measuring instruments, and with the comparison-condensers, and are provided whereby the capacity of at least one of the comparison-condensers can be altered, so that by adjustment, the capacity of the condenser placed in contact with the vapour, &c., can be ascertained.—A. S.

Thermo-element. A. Heil. Ger. Pat. 158,099, March 3, 1904.

The thermo-element claimed, the positive pole consists of an alloy of manganese and silver, for example 25 parts of silver to 75 parts of the latter. The manganese-silver alloy is stated to be more malleable and stronger than the antimony alloy generally used; it is also more resistant to the action of acids than the latter, as it melts only at about 1000° C.—A. S.

(B.)—ELECTRO-METALLURGY.

Coated Iron and Steel Goods; Comparison Tests on the Coating of — by the Hot and Electrolytic Methods. J. J. J. Z. Elektrochem, 1905, 11, 335—338.

Tests clearly prove the superiority of the electrolytic method both as regards its adhesion when the metal is subjected to mechanical tests, as also in its resistance to atmospheric corrosion.

Moreover, the amount of zinc required for satisfactory galvanising is much less in the electrolytic than in the hot

galvanising process. The author ascribes this to the contamination of the zinc, to the irregularity of the deposit and to the enclosed salts (zinc and ammonium chlorides) in the latter case. However, even in the electrolytic process, it is advisable to use only such electrolytes as are unlikely to corrode the iron should they become enclosed in the deposit. Otherwise the electrolytic deposit is not so advantageous over those obtainable by hot galvanising.

—R. S. H.

Metallic Wires; Electrolytic Production of Fine —. H. Abraham. Comptes rend., 1905, 140, 1444—1445.

The wire, the cross-section of which it is desired to reduce, is made the anode in an electrolytic cell; it is suspended from the ends of two metallic leads, to one of which each of its ends is soldered, and is kept in the bath (a developing tray answers well) by two little glass hooks. The electrolyte must be very dilute, so as to interpose considerable resistance, and the current very small, so that the density all over the surface of the wire may be uniform. Water containing under 1 per cent. of copper sulphate or silver nitrate, and a current density of 0.01 ampere per sq. cm. of surface will answer.—J. T. D.

ENGLISH PATENTS.

Metals; Process for the Ornamentation of — and the Production of Metal Marqueterie. S. Cowper-Coles and S. Cowper-Coles and Co., London. Eng. Pat. 12,174, May 28, 1904.

The desired ornamentation is transferred or painted on the metal article, those parts being left exposed upon which the second metal is to be inlaid, and the exposed portions are mechanically and chemically cleaned. A second metal is then electrolytically deposited upon the exposed portion in a suitable bath, and after removal of the "stopping-off" material, the article is heated sufficiently and for so long as to cause an alloy to form between the two metals. For instance, if the article to be ornamented is of copper, on the exposed portions of which zinc is electro-deposited, brass is formed; "the outer coating is practically of pure zinc, next to which is a layer of zinc-copper alloy, and below this a layer of copper-zinc alloy."—E. S.

Electrotypes; Improved Method of Producing —. S. Cowper-Coles and Co., Ltd., and S. Cowper-Coles, London. Eng. Pat. 13,012, June 8, 1904.

The electrolytic bath is divided into compartments, and the mould, acting as the cathode, is suspended in the electrolyte at a distance from the anode determined by the character of the design to be produced. The electrolyte is circulated by means of a pump, the vertical partitions, which support the electrodes, causing the liquid to take a horizontal zig-zag course through the various compartments. The electrolyte may, by means of channels furnished with sluice-gates, be allowed to fall through a perforated plate into a lower filtering chamber, thus becoming aerated and then passing in a vertical zig-zag course over material acting as a sieve. The liquid finally passes into a settling tank, and, from the latter, the pump draws off the liquid for circulation through the electrolytic vessel.—B. N.

Electro-Plating Metallic Articles; Apparatus for —. Rudge-Whitworth, Ltd., and J. V. Pugh, Coventry, and H. L. Heathcote, Birmingham. Eng. Pat. 16,648, July 28, 1904.

The articles are mounted on a rotating carrier, which is kept in rapid motion during the deposition of the metal. The vat is provided with a partition or wall and means for causing a rapid circulation of the electrolyte.—R. S. H.

UNITED STATES PATENTS.

Furnace; Electrical —. I. S. Prenner, Assignor to G. N. Brown, Scranton, Pa. U.S. Pat. 799,226, May 16, 1905.

The furnace, which is intended for smelting ores, &c., consists of a closed chamber, containing a stationary and

movable electrodes, the distances between the electrodes being regulated automatically in accordance with the strength of the arc current. The hearth of the furnace is fixed close to the end of the fixed electrode, and the material is fed on to it through a hopper, the discharge opening of which is controlled electrically, and in such a way that the feeding of material is stopped as soon as the arc circuit is broken.—T. E. B.

Metallic Compounds; [Electrical] Process of Reducing — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,389, May 23, 1905.

This invention relates to a process of reducing compounds or ores of metals, the temperatures of reduction and volatilisation of which are approximately the same. A charge of the compound and a reducing agent, acting as a resistance conductor, is heated in an electric incandescence furnace, and the current density through the charge is increased to a point where reduction is effected, the maximum temperature being maintained constant at a point at which volatilisation of the reduced metal is prevented. The latter is removed from the region of maximum temperature as it is reduced, by introducing into the furnace an alloying metal, such as iron, and causing it to percolate downward through the charge, thus collecting the scattered particles of reduced metal. The slag and reduced metal are tapped from the furnace at different levels.—B. N.

Metallic Compounds; [Electrical] Process of Reducing — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,390, May 23, 1905.

The claims are similar to those in U.S. Pat. 790,389 (see preceding abstract), but in addition the process is claimed in conjunction with an electric arc furnace.—B. N.

Metallic Compounds; [Electrical] Process of Smelting — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,391, May 23, 1905.

This invention relates to a process of smelting a metallic compound or compounds, containing iron or iron and chromium, for the formation of metallic products, such as iron or ferrochromium, containing a definite percentage of carbon. An electric arc is established within the electrically-conductive charge containing a predetermined amount of carbon, and the zone of reduction is surrounded by a considerable quantity of the charge, thus protecting the electrodes from the oxidising and cooling effect of the atmosphere. The minimum potential difference, requisite to effect reduction, is maintained between the electrodes, thereby preventing loss of electric current by leakage through the charge and by heat radiation. The reduced metal, or alloy, and the slag are tapped from the furnace at different levels.—B. N.

Ferrochromium; [Electrical] Process of Producing — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,392, May 23, 1905.

This invention relates to a process similar to that described in U.S. Pat. 790,391 (see preceding abstract) for obtaining a metal or metals, such as ferrochromium, practically free from or low in carbon. The electric current is passed through the charge of carbon and combined iron and chromium, acting as a resistance conductor, and the current density is increased to a point where reduction is effected, the reduced metal or alloy being separated and maintained out of contact with the carbon in the charge by an intermediate layer of slag.—B. N.

Ferrochromium; [Electrical] Process of Smelting Iron Ores and Producing — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,393, May 23, 1905.

The process is similar to that described in U.S. Pat. 790,392 (see preceding abstract), the charge of ore containing iron and an alloying metal and carbon, being interposed between superposed metal electrodes, which are cooled in order to maintain them at a relatively low temperature. The molten alloy, containing a minimum or definite percentage of carbon, is allowed to settle on the lower electrode of the same material, which thus comprises

a liquid and solid portion, the latter being cooled. The density of the electric current increases as it passes through the charge. The liquid product is removed, and charge materials supplied as required.—B. N.

Ores; [Electrical] Process of Smelting Refractory — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,394, May 23, 1905.

The process is similar to that described in U.S. Pat. 790,393, (see preceding abstract) but is applied to the smelting of refractory ores, and it is mentioned that the charge is moved along the path of current flow.—B. N.

Metals or Alloys; [Electrical] Process of Producing Carbon — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,395, May 23, 1905.

This invention relates to a process for producing carbon metals or alloys, such as ferro-chromium, electrically smelting a charge containing an excess of carbon in order to first produce a material relatively rich in carbon. The high-carbon product is cast into an ingot, then broken into fragments, and the latter mixed with a decarburising agent containing calcium, capable of producing a non-gaseous carburised by-product, such as calcium carbide. The mixture, acting as a resistance conductor, is electrically heated to the temperature requisite to effect decarburisation, and the carbide and carburised product are separately removed, fresh charge materials being supplied as required.—B. N.

Metals or Alloys; [Electrical] Process of Producing Carbon — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,396, May 23, 1905.

This invention is similar to that described in U.S. Pat. 790,395, (see preceding abstract) but the process is a continuous one. The charge is smelted, using carbon electrodes, the latter being protected from oxidation by a considerable body of the charge. The slag is removed, and the high-carbon product is run from the zone of reduction into a separate chamber provided with walls containing no carbon. In this chamber the material is electrically heated with lime, the slag, by-product carbide and low-carbon product being withdrawn, and a fresh charge mixture and decarburising agent supplied as required.—B. N.

Metals or Alloys; [Electrical] Process of Producing Carbon — E. F. Price, Niagara Falls, N.Y. U.S. Pat. 790,397, May 23, 1905.

This process is similar to that described in U.S. Pat. 790,396, (see preceding abstract) but the high-carbon product is caused to percolate through a granular material, such as lime, the latter being heated to a high temperature by interposing it as a resistance conductor in an electrical circuit in a separate chamber.—B. N.

FRENCH PATENT.

Minerals and Metallurgical Products; Process of Treating — in the Electric Furnace. K. F. Fr. Pat. 349,226, Dec. 20, 1904.

METALS and their alloys are extracted from minerals and other substances by a process of fractional vaporisation without the addition of reducing agents, or the temperature of the electric current may be regulated in order to obtain the separate vaporisation of one of the metals.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Fatty Oils; Influence of Atmospheric Oxidation upon Analytical Constants of — H. C. Sherman and M. J. Falk. J. Amer. Chem. Soc., 1905, 27, 605-618.

THE authors have previously shown (this J., 1903, 25, 1003) that the change which takes place when non-drying and semi-drying oils are exposed to the air, consists mainly in the addition of hydroxyl groups, two of these groups

(B).—RESINS, VARNISHES.

Turpentine; Alteration of the Rotatory Power of Oil of —. L. Raby. Ann. Chim. anal. appl. 1905, 10, 147. Chem. Centr., 1905, 1, 1471.

RIBAN has shown that the rotatory power of neutral and perfectly anhydrous oil of turpentine is not altered on distillation. If, however, oil of turpentine containing moisture, and of acid reaction, be distilled, the optical rotation of the distillate is only from 27° to 28° instead of the customary 35° to 37° . The rotatory power gradually attains the higher value if the distillate be preserved for about four months.—A. S.

ENGLISH PATENT.

Indoleum, Floor Cloths and the like; Manufacture of —. L. W. Smith, Calcutta. Eng. Pat. 6371, March 25, 1905.

POWDERED "sola" (a common Indian plant) is substituted for the cork or wood meal usually employed in making indoleum. The pith only may be used for special purposes, the outer bark of the sola being removed.—A. G. L.

UNITED STATES PATENT.

Turpentine; Apparatus for Distilling —. H. Hirsh, Eastman, Ga. U.S. Pat. 790,635, May 23, 1905.

THE apparatus consists of a vertical cylindrical retort provided with feeding and discharging doors, and with a dome-shaped top, to which is connected a pipe leading to the condenser. Within the cylindrical portion of the retort is a supply-pipe forming three sides of a rectangle, with the open side opposite the door, and with loops rising from the rectangular portion and extending to the dome. The pipes inside the retort are perforated.—A. S.

FRENCH PATENT.

Gum Resins; [Electrical] Treatment of — and Residual Product [Sylvine]. A. Nodon. First Addition, dated March 1, 1904, to Fr. Pat. 348,653, Feb. 16, 1904; this J., 1905, 552.

THE use of alkali carbonates instead of the hydroxides mentioned in the main patent (*loc. cit.*) is claimed; the mixture is distilled in the same manner, and the residue which contains an excess of alkali, but the properties of which are precisely similar to those obtained with the hydroxide, is designated "Sylvine No. 2." Inasmuch as it is found that the surfaces of the poles of the electric heater become covered with an insulating material, it is proposed to insert between the poles solid resistances imbedded in the pasty mass.—M. J. S.

(C).—INDIA-RUBBER, ETC.

India-rubber; New Method of Preparing —. P. J. Burgess. Chem. & Drug, 66, 911.

A METHOD of coagulating the latex of *Ficus elastica*, the tree from which "Rambong" rubber is obtained, is recommended by the Straits Government analyst, Mr. P. J. Burgess. On account of the acid nature of the latex from this tree, it is not possible to coagulate it by the acetic acid method as usually employed for *Hevea brasiliensis*. Up to the present the plan has been to expose the latex to the combined action of the sun and air, and if necessary to artificial heat. The method now advocated consists in warming the latex to 40° C. and treating it with a 2 per cent. solution of tannic acid. By gentle beating, the mixture in a few minutes sets to a cream, and on agitation becomes coherent, when it can be rolled or washed and prepared for the market. This is stated to be a practical process for use on rubber estates. By the use of this process it is possible to convert the coagulated latex into rubber with a saving of several months' time, and a better article is said to be produced.

XIV.—TANNING, LEATHER, GLUE, SIZ.

Hides; Weighing — in Water. C. E. Park and G. H. Russell. Collegium 1905, 161—164, 171—172.

THE customary method employed in order to ascertain the percentage yield of leather from a given weight of hide is to weigh the goods after unhairing and allowing so many hours for drainage, and afterwards weigh the tanned leather. Sometimes the butts, shoulders and bellies are weighed separately, and the percentage yield of leather estimated by multiplying the pelt by a certain percentage, e.g., 70 per cent. in the butt pelt, 52 per cent. with belly pelt, and 55 per cent. with shoulder pelt. Owing to the very varied conditions under which the pelt may be weighed, and the amount of water contained in different packs, this method is unreliable. The authors have proved the practicality of determining dry substances by weighing the goods in water as suggested by H. R. Procter and Carini. Hides are taken direct from the washing or deliming and are then weighed singly on a spring ("Sal" balance, and again after completely immersing in a length of copper wire connecting the hide to the bottom of the tank. The weight in water is approximately one sixteenth the weight in the air. The sp. gr. of the dry substance of plumped butts having been found to be 1.425 and of plumped shoulders and bellies 1.375, the weight of dry hide substance may be calculated by multiplying the weight in water by the factor 3.38 in the butts and 3.754 in that of bellies and shoulder pieces. The factor being calculated by division of the sp. gr. of the pelt by the difference between this sp. gr. and that of water. Having determined the weight of dry hide substance, it is possible, after ascertaining the percentage of hide substance contained in a sample of tanned leather by Kjeldahl's method, to predict the finished leather should weigh. Varying degrees of plumpness affect the sp. gr. of the pelt; a factor representing the degree of plumpness and termed the "specific volume" can be obtained by deducting the weight of goods in water from the weight of goods in air and dividing by the weight of dry hide substance. This factor remains practically constant during the whole tanning process, and gives a true indication of the condition of the goods prior to tanning. Butts gave 3.0 to 3.8, shoulders 4.0 to 4.7 e.e. of water per gram of dry hide substance. Carini has shown that the more plump the goods the more rapid the absorption of the tannin, and the greater the weight of leather produced. He gives the relation between the water weight and that of pelt dried at 100° C. as follows:—

Hides from "Soaks," with hair on ..	3.216	45
Hides from "Limes," after unhairing ..	3.353	425
Hides treated with sodium sulphide, and unhaired ..	3.227	441

The authors give the following results as the average of nine determinations in each case for limed sole hides:—

	Sp. gr. Assumed.	Dry Substance per cent.	"A" cent. S. 100° Vol.
Whole hides ..	1.4250	26.82	3
Bellies ..	1.3725	22.06	7
Shoulders ..	1.3760	21.19	6

VI.—SUGAR, STARCH, GUM, Etc.

as *Fuel*. R. Terry, S. Arnold and H. Fisher.
Coal of Mines Quarterly, 1905, 26, 283-302.

33 has been burned as a fuel in Hawaii, Java, Cuba
pt. The more sugar extracted from the molasses,
its usefulness excepting for fuel, for the manu-
of alcohol and for feeding cattle. At present the
used is to sprinkle the molasses on the bagasse as
the last mill on its way to the furnace, in the pro-
of 50 lb. to the ton of cane ground, or 1 part of
to 5 of bagasse. It is doubtful if it would pay
the molasses on to the burning bagasse owing to
entailed by the steam used for atomising, an item
oes not occur in the present method of sprinkling ;
, in factories where diffusion is used, including
et-sugar houses, where there is no bagasse, this
of spraying the molasses on to a coal fire or
with oil could be used if desirable. The authors
periments on the efficiency of molasses when
d in conjunction with fuel oil or residues of
n petroleum, and conclude that molasses may
evaporation of 2 lb. of water per lb. of molasses
proper conditions. Preheating of the molasses to
rendered it sufficiently fluid to obviate clogging in
ner, and also facilitated the atomisation.

ses is purified by osmosis and mixed with a sugar
the mixture being then boiled to grain and the
ag sugar being subsequently refined if necessary.
Excess water from the initial molasses is con-
centrated and again subjected to osmosis. The molasses
obtained from this second operation is mixed with the
water molasses for osmosis, whilst the last exosmose
is treated with sodium nitrate, boiled and crystallised
in large tanks for the separation of the potassium salts.
The washings of the crystals being reconcentrated with a
small quantity of saline liquors.—J. F. B.

Molluscs; Process of Treating F. Heus
 Francisco, Cal. U.S. Pat. 790,035, May 16, 1905.

MOLASSES and "osmosing" water are caused to flow through the osmose vessel in contrary directions, the molasses being introduced at the bottom and the water at the top. The "osmosed" molasses is collected in a special reservoir at the top of the molasses chambers, and a portion of it is concentrated to a suitable extent and returned to the reservoir. The concentrated "osmosed" molasses from this reservoir is allowed to percolate into the molasses chambers of the osmosis apparatus, thereby increasing the mean density of the crude molasses undergoing osmosis therein. — J. F. B.

Mycoderma Yeasts; Some New Varieties of -
T. Takahashi. Bull. Coll. Agric., Tokyo, 1905, 6,
387-402. Chem. Centr., 1905, 1, 1176.

THE author has isolated and examined several varieties of sporulating mycoderma yeasts from saké, koji, and saké mashes. It was not found possible to decide whether these varieties were identical or not with the mycoderma yeasts which have been described previously. Some of the new varieties have the power of assimilating nitrogen from nitrites, in the presence of glycerol as the source of carbon, whilst some will develop in saké containing from 10.77 to 13.32 per cent. by weight of alcohol. Most of the new varieties are capable of producing from koji extract considerable quantities of methyl alcohol; this alcohol, also, is frequently present in ordinary saké. All of the mycoderma yeasts isolated, produce acetic acid from alcohol, and some also produce it from glycerol. Some of the new varieties produce also butyric acid and, occasionally, formic acid in sugar solutions.—A. S.

Fusel Oil ; Origin of —. F. Ehrlich. Z. Ver. deutsch. Zucker-Ind., 1905, 539—567.

THE experiments recorded by the author corroborate the hypothesis, first enunciated by A. Müller in 1857, that the fusel oil of fermentation is a product of the action of yeast upon the albuminoid derivatives of the wort, and that the sugar plays no part in its formation. The author concludes that the two amyl alcohols of fusel oil are derived from leucine and isoleucine, and that the other higher alcohols and a portion of the fatty acids are derived from other members of the amino-acid series. It was found that, whereas pure-cultivated yeast acting upon pure sugar yielded only a trace of fusel oil, the same mixture yielded inactive amyl alcohol when leucine was added, and *d*-amyl alcohol when isoleucine was added, the quantity of amyl alcohol produced being approximately equivalent to that of the amino-acid consumed. It was also found in the case of leucine, that the yeast had selectively attacked this racemic amino-acid, and had confined its action solely to the *l*-leucine, leaving the *d*-leucine unchanged.

It is assumed that the small quantity of fuel-oil produced in the fermentation of pure sugar is derived from the amino-acids of the yeast, the quantity being limited by the re-synthesis of albumin from the products of the proteolytic enzyme. It would appear that amyl alcohol is only formed in appreciable quantities when the yeast is supplied with an excess of amino-acids. Three hypotheses as to the mechanism of the formation of amyl alcohol from leucine are discussed. The most likely explanation is that the amino-acid combines with water and separates ammonia under the action of the yeast enzymes, with the production of the corresponding hydroxy-acid, and that this latter is decomposed into carbon dioxide and amyl alcohol in the same manner as lactic acid probably yields carbon dioxide and ethyl alcohol under similar conditions. It is suggested that isobutyl alcohol is produced from α -amino-isovaleric acid and *n*-propyl alcohol from glutamic acid during fermentation.—J. F. B.

Ethyl Alcohol; Acidity of Commercial — and its Variations during Storage. R. Duchesneau and J. Pourden. *Comptes rend.*, 1905, **140**, 1466-1468.

THE authors have determined that alcohol is gradually oxidised in contact with air with the production of acetic acid. The degree of acidity is liable to vary more or less sensibly in both directions in comparatively short intervals of time during storage in glass vessels. The variations in the acidity may be due to differences between the rapidity of the oxidation of the alcohol and the saturation of the acid by the bases of the glass. Spirits of old manufacture scarcely ever contain more than 0.05 gram of free acid per litre, and their acidity only changes when the containing vessel is changed. Nevertheless, whenever the free acidity of a spirit is neutralised, the acidity rapidly reappears and rises to a maximum point depending on the nature of the spirit. The acidity generally increases more rapidly in vessels of green glass than in those of white glass.—J. F. B.

Soy Extracts; Apparatus for Making —. T. Suzuki, Sumamura, Japan. U.S. Pat., 785,776, March 28, 1905.

THE apparatus consists of three vacuum evaporating pans, in series, working on the multiple effect system. The pans consist of a cylindrical drum containing the extract to be evaporated, surrounded by a steam jacket; a rotary stirring device is provided in each drum for keeping the liquid in motion, and the extremities of the stirring arms are fitted with brushes. The concentrated extract from the last evaporator is discharged into a vacuum finishing receptacle heated by hot water. This receptacle is divided into two sections, containing shelves composed of hot-water tubes, upon which trays containing the concentrated extract are placed for final drying; the air can be exhausted from either section independently.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS

(A.)—FOODS.

Foodstuffs; Application of Freezing in the Preparation of certain — in Japan. T. Katayama. *Bull. Agric.*, Tokyo, 1905, **6**, 433-436. *Chem. Centr.*, **1**, 1598.

THE author describes the method of preparing the Japanese foodstuffs: *Kori-Konnyaku*, *Kori-Tofu*, *Kori-Mochi* (*Kori*=Ice). *Konnyaku* is obtained the roots of *Amorphophallus Rivieri* or *Conop. Konnyaku*, containing chiefly mannin, by boiling lime-water, which destroys the acrid taste of the Tofu is prepared by treating the hot aqueous extract of soja beans with solutions of calcium and magnesium salts, whereby the alkali phosphates, which retain protein substances in solution, are decomposed, and protein bodies are precipitated. *Mochi* is obtained from rice. All three products are formed into tablets of soft pasty consistence, and are then subjected to a freezing process, whereby the greater part of the water is removed and the preparations are rendered stable. Owing to the formation of ice crystals in the paste, the products acquire a very porous structure, which not only increases digestibility, but also accelerates the drying process to a degree that the injurious action of bacterial fungi is stated to be excluded.—A. S.

Öidium Lactis and the Ripening of Cream and Cheese. J. Arthaud-Berthet. *Comptes rend.*, 1905, **140**, 13-1477.

Öidium lactis is present almost universally in the dairy and the author has isolated several varieties of it and studied their action upon the various dairy products. Sterile milk or cream is obtained by a process of pasteurisation at 65° C., for a period of 5 minutes. Products pasteurised in this manner preserve all their natural characteristics and are devoid of the peculiar flavour due to boiling. The presence of *O. lactis* in cream is one of the most dangerous causes of rancidity of butter, but butter prepared from pasteurised cream keeps much longer than the unpasteurised product. The flavour of the finest butters can be reproduced by infecting pasteurised cream with lactic ferments, yeasts and casein ferments taken from good butters. In cheese making, *O. lactis* frequently the cause of a sickness known under the name of "grasse" or "frisure," especially on cheeses made with mucedine. But in certain cases it plays a favourable and important part in the ripening. The ferments are the most indispensable of the micro-organisms in the dairy; they act as auto-regulators by reason of the lactic acid they produce from the lactose, which prevents the exaggerated development of *Öidium*, and also of butyric and certain injurious casein ferments. They assist the pressing of the cheese and facilitate the drainage of the whey. *O. lactis* consumes the lactic acid on the surface of the cheese, and thus induces the production of ammonia. It plays both a direct and indirect part in determining the flavour by permitting the growth of other bacteria in symbiosis and by the secretion of necessary enzymes. The casein is ripened by the specific action of the enzyme casease, and by the solvent influence of ammonia; the physical condition of ripened cheese can be imitated in sterile products by the use of ammonia alone.—J. F. B.

powder or Meal; Process for Making a —. H. W. Stringfellow, London. From E. Maragliano, Rome. Eng. Pat. 15,440, July 11, 1904.

divided meat, previously freed from fat and bone, is placed in a vessel immersed in hot water, and is constantly stirred. The volatile portion is condensed, and the meat is then cooled for about 24 hours in a refrigerating chamber, afterwards ground to a powder, the latter completely dried in a closed chamber over sulphuric acid. Over the meal thus obtained may be sprinkled the volatile portion condensed during the first part of the process. The mixture is then sterilised in autoclaves, and filled into air-tight tins.—W. P. S.

Separators; Impts. in —. J. Meys, Siegen, Germany. Eng. Pat. 4841, March 8, 1905.

The separator consists of vertical curved separating walls, arranged in the separator drum. The walls are from five to ten in number and are connected tangentially with the drum rim, their inner edges extending up to or into the cream zone. The separating walls are connected with each other by means of bolts. A channel formed by a disc and the bottom of the drum provides an outlet for the skimmed milk, whilst the cream flows off through a pipe at the centre.—W. P. S.

Separators; Centrifugal —. J. Melotte, Remich, Belgium. Eng. Pat. 6102, March 23, 1905; Int. Conv., March 20, 1904.

Adjustable ribs or projections are provided between the drum and false-bottom of the drum. By shortening or lengthening the projections, the quantity of milk passing with the cream is proportionally increased or decreased. This arrangement is of particular use in separating milks of varying richness. The alteration in the height of the ribs may be effected by a screw, or other means.—W. P. S.

UNITED STATES PATENT.

Method of Making Evaporated —. J. A. Just, New York, N.Y. U.S. Pat. 789,853, May 16, 1905.

The milk is partially digested by treatment with pepsin at a temperature of 100° to 110° F., and then quickly evaporated in the form of a film at a temperature of not more than 212° F. Fat may be added to the milk after digestion, and milk sugar to the evaporated mixture. Lactose may also be added to the milk before proceeding with the digestion and evaporation. (See also Eng. Pat. 15,440; this J., 1905, 206.)—W. P. S.

GERMAN PATENT.

[Milk]; Process for the Concentration of —. A. Gürber, Berlin. Ger. Pat. 247,397, April 18, 1901.

Milks of all kinds, but especially milk, are concentrated by freezing out the solvent in a centrifugal separator, provided with a central rotating chamber containing a refrigerating agent.—A. S.

—SANITATION; WATER PURIFICATION.

ENGLISH PATENTS.

and other Refuse; Treatment and Utilisation of —. H. W. Stringfellow, Walthamstow, Essex. Eng. Pat. 15,439, May 7, 1904.

The object of the treatment is to convert the solid contents and soluble organic compounds of sewage, sludge, oil, household or trade refuse, and road sweepings into manures, and at the same time to obtain an unobjectionable effluent from the liquid portion of the sewage, &c. For this purpose, the sewage is treated with lime and aluminous products dissolved from iron-ore slag by sulphuric acid, and also with iron

solutions, lime and other chemicals, in order to precipitate the nitrogenous and phosphatic matters. Household refuse and the like, is, after sorting, treated with dry blast-furnace slag, a solution of an acid (sulphuric) being also added. The arrangement of tanks, automatic mixer, &c., is also claimed. W. P. S.

Sewage [Effluent]; Treatment of —. A. McLean, London, and W. Paterson, Dumfries. Eng. Pat. 22,724, Oct. 21, 1904.

The effluent from the settling tanks is allowed to flow into a number of receptacles on the false bottom of which is placed a filtering medium. The latter consists of a layer of asbestos fibre about $\frac{1}{2}$ in. in thickness, above which is placed a 3 in. layer of animal charcoal, and above this again a 3 in. layer of slag-wool or asbestos fibre. The layers may be of varying thickness, and each may be supported on a perforated tray. When necessary, the organic matter collecting on the filters can be burnt off, and the filters used again.—W. P. S.

Sludge or Drain Water; Apparatus for Separating Mud or Solid Matter from —, in a Practically Dry Condition. C. Kremer, Gr. Lichterfelde, and Ges. für Abwasserklärung m. b. H., Berlin. Eng. Pat. 544, Jan. 11, 1905.

The sludge is conveyed by means of a worm from a settling tank into a tall, vertical square vessel. The latter has a hinged bottom fitted with a discharge tap, and on this bottom are placed a perforated plate, a barred plate and a layer of filtering material, such as turf. A central pipe is fixed through the two plates and extends half the height of the box, where it receives a second pipe of smaller diameter and capable of sliding in it. This second pipe reaches up to and through a press filter at the top of the vessel. When the latter is screwed down, the exuding water passes down the two pipes and runs through the discharge pipe. A slide valve is provided to cut off the connection between the tank and filtering vessel, while the press is being screwed down. The cake of practically dry mud is removed by opening the hinged bottom of the vessel.—W. P. S.

GERMAN PATENT.

Liquids; Process for the Treatment [Sterilisation] of — with Ozone. E. Fischer. Ger. Pat. 158,693, May 29, 1903.

In the usual process of treating liquids with ozone by passing the gaseous mixture from the ozoniser into the sterilising-tower, the gas, after its first passage through the liquid, is made to pass, for the most part, through a pipe connecting the upper and lower portions of the sterilising-tower, so that the ozone is brought repeatedly into contact with the same liquid, before escaping.—A. S.

XIX.—PAPER, PASTEBOARD, Etc.

Cellulose Aceto-Sulphates. C. F. Cross, E. J. Bevan and J. F. Briggs. Ger. 1905, 38, 1859—1865.

When cellulose is treated with mixtures of acetic anhydride and glacial acetic acid containing increasing proportions of sulphuric acid, a series of mixed aceto-sulphuric cellulose esters is obtained, containing proportions of combined sulphuric acid ranging from 5 to 25 per cent. The formation of the members of this series takes place in a graduated manner, the particular equilibrium obtained being determined by the concentration of the sulphuric acid in the reacting mixture. The products can be approximately separated according to their solubilities in acetone, alcohol and water. The most definite member of the series contains 8.76 per cent. of combined sulphuric acid and yields 50.6 per cent. of acetic acid on saponification. It is insoluble in water, but soluble in acetone and in

hot aqueous alcohol; the alcoholic solutions solidify to a jelly on cooling. It is distinguished by a relatively high proportion of hygroscopic moisture (about 8 per cent.), and by a great capacity for absorbing water to form a voluminous hydrated jelly. The sulphuric acid group resists the saponifying action of alcoholic potash, and remains combined with the cellulose in the form of a sulphate perfectly soluble in water.

A lower position in the series is occupied by a substance which contains 5 per cent. of sulphuric acid, and which has less affinity for water than the above, and is insoluble in hot alcohol. As the proportion of sulphuric acid is increased, the products become entirely soluble in water, but they can be precipitated by brine; these products still preserve their colloid character as cellulose derivatives.

UNITED STATES PATENTS.

Paper; Process of Making Stretchable —. J. Arkell, Canajoharie, N.Y. W. J. Arkell and B. Arkell, Executors of said J. Arkell, deceased. U.S. Pat. 790,021, May 16, 1905.

A SUITABLE finished paper is passed through a "saturating bath," and then deposited on a smooth-surfaced roller, the surplus moisture is squeezed out by another roller, and the paper, while still damp, is "crowded back against itself" forming crinkles in the paper. The crinkled paper is then dried to render the crinkles permanent. The paper is extended laterally before being crinkled, and may, in one variety of the process, be passed through two baths in succession. The treated paper is capable of being stretched, and is suitable for packing purposes.—W. H. C.

Cotton Seed; Treatment of —. I. Kitsee, Philadelphia. U.S. Pat. 789,977, May 16, 1905.

COTTON seed with its adherent fibre is subjected to a process of nitration. The nitrated product is then treated with a solvent which dissolves the nitrocellulose, and the solution is separated from the residue of the seed.—J. F. B.

Cotton Seed; Treatment of —. I. Kitsee, Philadelphia. U.S. Pat. 789,978, May 16, 1905.

THE seed is first subjected to a treatment whereby the hull is broken and the kernel is separated. The hulls and the adherent fibres are then nitrated, the nitrated product is treated with a solvent, and the solution is separated from the residues of hulls.—J. F. B.

Triacetyl Cellulose. A. Eichengrün and T. Becker, Elberfeld, Germany. Assignors to Farbwerke, of Elberfeld Co., New York. U.S. Pat. 790,565, May 23, 1905.

SEE FR. Pat. 317,007 of 1901; this J., 1902, 870.—T. F. B.

FRENCH PATENT.

Celluloid; Non-inflammable —. P. Germain. Fr. Pat. 349,292, Dec. 8, 1904. Under Int. Conv., Sept. 19, 1904.

A NON-INFLAMMABLE celluloid is said to be produced by incorporating with the paste made from celluloid and acetone, some salt which, on heating, evolves a considerable quantity of gas which does not support combustion, e.g., a bicarbonate. Articles made of celluloid which are

non-porous, may be rendered porous by partial dissolving the camphor, when they are treated with as above. The fire-proofed material is then rendered non-porous by treatment with a small quantity of an acid and drying, which process is said to cover the celluloid with a thin non-porous layer.—T. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Bismuth Nitrites; Complex —. W. C. Ball. Soc. Trans., 1905, 87, 761–765.

Bismuth Sodium Ammonium Nitrite.—Powdered bismuth nitrate (10 grms.) was dissolved in a saturated solution of 15 grms. of ammonium nitrate at 0° C., and the solution poured gradually into an ice-cold, nearly saturated solution of 15 grms. of sodium nitrite, slightly acidified with nitrous fumes. The liquid was at once decanted, a precipitate drained on a porous tile, pressed, and between porous plates in a desiccator at 0° C. The product was obtained as bright yellow octahedra with a slight fluorescence; it had the composition $\text{Bi}(\text{NO}_2)_3 \cdot 2\text{NH}_4\text{NO}_2$, and decomposed slowly even at 0° C. *Bismuth Potassium Nitrite*.—This was obtained by passing nitrous fumes into a suspension of bismuth hydroxide in a concentrated potassium nitrite solution. It is an orange-coloured crystalline compound of the composition $\text{Bi}(\text{NO}_2)_3 \cdot 3\text{KNO}_2 \cdot \text{H}_2\text{O}$; it is immediately hydrolysed by water, but is stable at the ordinary temperature, and, unlike other compounds prepared, it does not detonate on being struck. *Other Complex Bismuth Nitrites*.—By mixing bismuth nitrate with a saturated solution of sodium nitrite, filtering in absence of air, and allowing the liquid to drop slowly into a saturated solution of ammonium nitrate at 0° C., the compound, $\text{Bi}(\text{NO}_2)_3 \cdot 2\text{NH}_4\text{NO}_2 \cdot \text{NH}_4\text{NO}_2$, was obtained in small canary-yellow crystals which gradually decompose even at 0° C. A double nitrite of bismuth, copper and ammonium, a triple nitrite of bismuth, copper and ammonium, a compound, probably a double nitrite of bismuth and cinchonine, and also an orange-coloured tetramethylammonium salt were also prepared.—A. S.

Phenol; Note on —. L. Reuter. Pharm. J., 1905, 74, 787–788.

IN order to prevent crystallised phenol from becoming rancid, it is recommended to add sulphurous anhydride to the melted phenol in quantity large enough to counteract the oxidising influence of the air or other oxidising agents. For carrying the method into effect, it is suggested to saturate liquefied phenol, containing 10 per cent. of water, with sulphurous anhydride until it contains about 10 per cent. of the latter. If from 25 to 75 c.c. of this solution are added to 200 kilos. of melted phenol, the latter can be preserved in a perfectly colourless condition for an almost unlimited length of time, whereas untreated phenol from the same source soon assumes a red colour, even when kept in a dark place and in tightly closed bottles. Seeing that a slight discoloration of phenol does not interfere with its application in medicine, the author considers that, to avoid mistakes and accidents, it would be advisable to tint all carbolic acid solutions with drugists uniformly with some organic colouring matter rather than use a preserving or decolorising agent.—B.

Adrenaline; Synthesis of Substances Allied to —. H. D. Dakin. Chem. Soc. Proc., 1905, 21, 154–157.

METHYLAMINOACETYL-CATECHOL, $\text{C}_6\text{H}_3(\text{OH})_2 \cdot \text{CO} \cdot \text{CH}_2 \cdot \text{N}(\text{CH}_3)_2$, is obtained by the action of methylamine on ethylacetylcatechol; it is crystalline, melts at 232° C., and forms crystalline salts, the solutions of which are faintly acid. According to the view generally held, adrenaline is regarded as the secondary alcohol corresponding to the ketone, methylaminoacetyl-catechol. By subjecting the latter compound or its bisulphite compound to electrolytic reduction, a base is obtained which is apparently not identical with, but has similar physiological properties closely allied to those of natural adrenaline. The free base is not precipitated from

as of its salts by sodium acetate, but separate
tion of ammonia, as a white, amorphous precipitate,
is very sparingly soluble in most neutral solvents,
se is extremely unstable in the dry condition, but
y kept for some time if suspended in water. Harries
bases of similar chemical and physiologic
ties were obtained by the electrolytic reduction of
e bases obtained by the action of various amines
croacetylcatechol.—A. S.

temisin (*δ-Oxy-santonin*). E. Wedekind and
A. Koch. Ber. 1905, 38, 1845—1851.

oxy-santonins have previously been described,
they being products of the living organism, viz.:
1 *β*-oxy-santonins, recovered from the urine of
s treated with santonin, and *γ*-santonin or artemisin
occurs together with santonin in *Artemisia maritima*.
du itself either resists the action of oxidising agents
broken down into simple products. The authors
prepared a fourth oxy-santonin by heating mono-
santonin under pressure, either with alcoholic potash
1° C., or with aqueous sodium acetate at 110°—115° C.;
product is *δ*-oxy-santonin or iso-artemisin $C_{15}H_{14}O_4$;
s at 214°—215° C. and has $[\alpha]_D^{20} = -108.6$; it
yields a phenylhydrazone melting at 176°—178° C.
osition and nature of the fourth oxygen atom
t yet been determined, but it would appear that
of a hydroxyl nature, since the new compound
either an acetyl nor a benzoyl derivative.—J. F. B.

Delencs. R. Willstaetter and H. Veraguth. Ber.
1905, 38, 1975—1984.

uthors applied methods used for obtaining hydro-
s from alkaloids of the tropine series to N-methyl
onine (*δ*-pelletierine). By exhaustive methylation
alkaloid they obtained cyclo-octadiene, an unsatura-
drocarbon of b. pt. 39.5° C., under 16.5 mm. pressure.
nstance is characterised by its tendency to poly-
to a crystalline mixture, principally consisting of
o-octadiene. It shares this property with cyclo-
liene (this J., 1896, 443). With regard to the
work of Harries (this J., 1905, 448), this property
hydrocarbon opens a view on the relation of india-
to the cyclo-octadienes. According to Harries,
aoutchouc is a polymeride of dimethylcyclo-
eno and the authors' hydrocarbon has possibly to
arded as the mother substance of india-rubber. The
carbon readily takes up bromine and reduces
ium permanganate. Cyclo-octatriene was obtained
ating the mixture of bromocyclo-octadienes with
hylamino and exhaustive methylation of the thus
d *δ*-dimethylgranatoline. This hydrocarbon of
36°—40° C. under 13 mm. pressure does not poly-
.—R. L.

r-grass Oil. H. Walbaum and O. Hühlig. J. prakt.
Chem., 1905, 71, 459—473.

constants of commercial ginger-grass oil should lie
in the following figures:—Sp. gr. at 15° C., 0.9277—
; $\alpha_D^{20} = -29^{\circ} 25'$ to $+22^{\circ} 40'$; acid value, 0.9 to
ester value, 9.5 to 24; saponification value after
lation, 130 to 172. The oil dissolves in 1 vol. of
r cent. alcohol, and in 2—3 vols. of 70 per cent.
ol. The constants of the samples used in this research
thin these figures. The oil distils from 50°—100° C.
—6 mm. From the lowest fractions, the following
aces were isolated:—*d-a-phellandrene*, b. pt. 175—
; $\alpha_D^{20} = +44^{\circ} 40'$; *dipentene*, b. pt. 176—178° C.,
+ $42^{\circ} 40'$ and *d-limonene*; the presence of each of
was confirmed by the preparation of characteristic
atives. An aldehyde $C_{10}H_{16}O$ was detected in the
ion boiling between 80° and 90° C. It boiled at
78° C. at 5 mm., at 221°—224° C. at 754 mm.,
r. at 15° C. 0.9351, $\alpha_D^{20} = +0^{\circ}$, $n_{D20}^{20} = 1.47348$. The
amount was about 0.2 per cent of the oil. By
ing the 80°—83.5° (5 mm.) fraction of the oil with
a neutral sodium sulphite solution, adding small
ities of acetic acid from time to time, and then
ng excess of sodium carbonate to the aqueous portion,
antity of inactive *carvone* was obtained, boiling at

230°—231° C. (See this J., 1904, 305.) The acrolein
portion (50—60 per cent.) of the oil boiled between 82° and
95° C. at 5 mm. This fraction was dissolved in benzene
and then pyridine and benzoyl chloride added. On
steam-distillation, the benzene acid ester of *geraniol* and
a new alcohol, $C_{10}H_{18}O$, remained behind. The geraniol
was removed by shaking with anhydrous calcium chloride,
and then boiled at 229°—230° C. The portion not affected
by the calcium chloride was treated with 90 per cent.
formic acid at 80° C. to convert the remaining geraniol
into terpenes. After fractionation, this new alcohol was
obtained as a colourless, slightly viscous oil, with a
characteristic odour, resembling that of terpinol. It
boils at 226—227° C. at 767 mm., and 92—93.5° C. at
5 mm.; sp. gr. at 15° C. 0.9510, $\alpha_D^{20} = +13^{\circ} 18'$; $n_{D20}^{20} =$
1.49629. By working with an oil of hexo-rotation, a hexo-
rotatory modification of the alcohol was obtained with the
following constants: b. pt. 228—229° at 755 mm., and
94—96° at 4—5 mm.; sp. gr. at 15° C. 0.9536; $\alpha_D^{20} = +12^{\circ} 5'$;
 $n_{D20}^{20} = 1.49761$. Its properties agree with those of
dihydrocarvonic alcohol.—F. S.

Cananga: *Essential Oil of* —. *Adulteration with "Cocoa
Butter" and Resin*. Schimmel's Report, May, 1905, 19.

CANANGA oil is frequently adulterated with "cocoanut
fat," in some cases to the extent of 50 per cent. Such
oil shows a separation of solid matter at normal tem-
peratures, whereas the pure oil does not congeal even
when immersed in a freezing mixture. Both this
adulterant and resin are detected by submitting the oil to
steam distillation, when the residue from pure oil does not
exceed 5 per cent.

Pure cananga oil has the following characters:—Sp. gr.
at 15° C. 0.910 to 0.950; $\alpha_D^{20} = -17^{\circ}$ to -55° ; saponification
value, 10 to 36. —J. O. B.

Caraway: *Constituents of Essential Oil of* —. Schimmel's Report, May, 1905, 19—21.

CARAWAY oil, in common with other oils derived from
Umbelliferous fruits, contains a trace of a base with a
peculiar odour. In addition to carvone and carvene,
dihydrocarvone and dihydrocarveol are found to be
present in the oil. —J. O. B.

Copaiba Oleoresin [*Copaiba "Balsam"*]. Schimmel's
Report, May, 1905, 24.

THREE varieties of copaiba "balsam" examined had the
following characters:—

Para Balsam.—Sp. gr., 0.9692; $\alpha_D^{20} = -44^{\circ} 21'$; $n_{D20}^{20} =$
1.51425; acid value, 60.75; saponification value, 64.72.

Bahia Balsam.—Sp. gr., 0.9603; $\alpha_D^{20} = +9^{\circ} 18'$; $n_{D20}^{20} =$
1.50693; acid value, 57.90; saponification value, 67.40.

Angostura Balsam.—Sp. gr., 0.9882; $\alpha_D^{20} = +26^{\circ} 15'$; $n_{D20}^{20} =$
1.51603; acid value, 86.54; saponification value, 96.41.
The above figures for the saponification value were obtained
by Dieterich's cold saponification method; by the hot
process, official in the Ph. G. IV., lower figures resulted.

All three "balsams" behaved similarly with light
petroleum spirit, giving at first a clear solution, becoming
turbid with more of the solvent, finally forming a flo-
cculent separation. All dissolved to a clear solution in
chloroform. Para and Angostura balsams also gave clear
solutions in alcohol and in amyl alcohol; but Bahia
balsam gave cloudy solutions with both of these solvents.

Essential Oil of Para Balsam.—Yield, 62.5 per cent.;
colour, yellow; sp. gr., 0.9180 at 15°; $\alpha_D^{20} = -75^{\circ} 48'$; $n_{D20}^{20} =$
1.50096; acid value, 3.14; ester value, *nil*; solubility
in 95 per cent. alcohol, 1:7.5 to 1:8.

Essential Oil of Bahia Balsam.—Yield, 61.93 per cent.;
colour, faint yellow; sp. gr., 8982 at 15° C.; $\alpha_D^{20} = -9^{\circ} 37'$;
 $n_D^{20} = 1.49460$; acid value, 7.89; saponification value,
9.82; solubility in 95 per cent. alcohol, 1:8 to 1:10 with
slight turbidity.

Essential Oil of Angostura Balsam.—Yield, 52.3 per
cent.; colour, faintly green; sp. gr., 0.9161; $\alpha_D^{20} = -2^{\circ} 20'$;
 $n_D^{20} = 1.50169$; acid value, 10.89; ester value, *nil*;
solubility in 95 per cent. alcohol, 1:5.5. —J. O. B.

Cypress [*Cupressus sempervirens*]: *Essential Oil of* —. Schimmel's Report, May, 1905, 26—27.

French Distilled Cypress Leaf Oil.—The oil distilled in

the South of France from fresh material has the following characters:—Sp. gr. at 15° C., 0.868 to 0.878; d_4^{20} to +31°; acid value, 0; ester value, 5 to 10; acetyl value, 10 to 15; solubility, 1.5 to 1.6 and more in 90 per cent. alcohol.

German Distilled Cypress Leaf Oil, from partially dried French material, has the sp. gr., 0.880 to 0.892; d_4^{20} +4° to +18°; acid value, 1.5 to 3.0; ester value, 15 to 22; acetyl value, 43 to 49; solubility in 90 per cent. alcohol, 1:2 to 1:6 or more.

French Distilled Cypress Fruit Oil has the sp. gr., 0.866 at 15° C.; d_4^{20} +30° 48'; acid value, 0; ester value, 6.74; acetyl value, 11.78; solubility in 90 per cent. alcohol, 1:6 and more.—J. O. B.

Cypress [Cupressus lambertiana]; Essential Oil of ——. Schimmel's Report, May, 1905, 83.

THE oil, distilled in the South of France, has a balsm-like odour probably due to a small amount of citronellal. Aldehydes were detected by the bisulphite reaction, but the amount present was too small to permit of identification. The non-aldehydic portion had a pepper-like odour, and may contain cymene. The oil had the following characters:—Sp. gr. at 15° C., 0.8656; d_4^{20} +31° 53'; acid value, 1.5; ester value, 13.9; acetyl value, 50.82; solubility in 90 per cent. alcohol, 2:1, and more; with 80 per cent. alcohol the 1:9 or 1:10 solutions are cloudy.

—J. O. B.

Hops; Essential Oil of —, Adulterated with Gurjun Balsam. Schimmel's Report, May, 1905, 49.

ADULTERATION with gurjun balsam is recorded in a specimen of hop oil. The sophisticated oil, which had a faint, greenish fluorescence, had the sp. gr., 0.9189, d_4^{20} +40° 40'; when fractionated, the lavo-rotation of the fractions increased up to +86° 50'. Genuine hop oil has the sp. gr. 0.855 to 0.880 and is almost inactive optically, as are its fractions.—J. O. B.

Lavender; Adulteration of Essential Oil of ——. Schimmel's Report, May, 1905, 50.

THE scarcity of lavender oil and the consequent high prices ruling have occasioned the appearance of much adulterated lavender oil in the market. The chief adulterants used are oils of turpentine, rosemary, spike, and the so-called Spanish lavender oil.

Turpentine oil lowers the sp. gr. and solubility, and affects the rotation, whilst French turpentine oil increases the normal lavo-rotation of lavender oil, and American turpentine lessens it. *Spike oil* increases the sp. gr. and lowers the rotation, but does not affect the solubility. *Spanish lavender oil* behaves like spike oil, but has less influence on the rotation, while *rosemary oil* affects the constants similarly, and renders the oil less soluble. All these oils, having lower ester values, considerably lower the ester content.

The characters of *pure French lavender oil* are—Sp. gr., 0.882 to 0.895; d_4^{20} +3° to +9°; ester content, 30–40 per cent. or more (calculated as linalyl acetate); solubility in 70 per cent. alcohol, 1:2 or 1:3, and more, with slight opalescence in oils rich in ester.

A fictitious ester value was found to be given to one sample of lavender oil adulterated with Spanish lavender oil, by the addition of *thyl succinate*. In addition to determining the ester value, it is necessary, therefore, when examining lavender oil, to also ascertain the nature of the ester by liberating and identifying the acid and alcohol after saponification.—J. O. B.

Patchouli Leaves; A Basic Constituent of Essential Oil of ——. Schimmel's Report, May, 1905, 60–61.

FURTHER details are now given of one of the two basic bodies previously recorded (this J., 1904, 679). On prolonged standing, a considerable crop of a crystalline hydrochloride was obtained, which, after purifying by recrystallisation from benzene, had the m. pt. 175° C., and the formula $C_{14}H_{23}NO.HCl$. The crystalline platinum chloride, $(C_{14}H_{23}NO.HCl)_2PtCl_4$ had the m. pt. 175° C.

—J. O. B.

Peppermint; Essential Oil of French ——. Schimmel's Report, May, 1905, 6.

ALTHOUGH peppermint is grown in considerable quantity in the South of France, and oil is produced there, it does not appear in commerce, since the whole is consumed in the country of its production.

Three specimens recently examined had the following characters:—Sp. gr. from 0.9108 to 0.9249; d_4^{20} +5° 20' to +35° 18'; menthol as esters 9.95 to 20.81 per cent. total menthol 45.75 to 69.29 per cent. Only one specimen was soluble in 70 per cent. alcohol 1:3.5; the others were insoluble 1:10. All showed opalescence on further dilution with 80 per cent. alcohol, due to separation trace of a paraffin. The marked variation in the three samples, attributed to differences in the maturity of plants, is also probably influenced by conditions of soil and culture.—J. O. B.

Lemon "Petitgrain" and Sweet Orange "Petitgrain"; Essential Oils of ——. Roure-Bertrand Fils, through Schimmel's Report, May, 1905, 64–65.

"*Lemon petitgrain oil*" obtained from the twigs and leaves of *Citrus limonum* is yellow in colour, and has the following characters and constituents:—Sp. gr. at 15° C., 0.8824; d_4^{20} +21° 8'; n_{D20}^{20} = 1.4725; citral, 24 per cent. citronellal, none; ester content (calculated as geranyl acetate) 10.5 per cent. Total alcohols 19.4 per cent. comprising 11.6 per cent. of geraniol. The oil closely resembles "sweet orange petitgrain oil."

"*Orange Petitgrain Oil*" from the leaves and twigs of *Citrus aurantium* is also yellow; sp. gr. 0.8602; d_4^{20} +56° 46'; n_{D20}^{20} = 1.472; it contains 4 per cent. of citral, 4.1 per cent. of esters, total alcohols 19.7 per cent. of which 12.7 per cent. was geraniol; dextro-camphor and limonene were also detected with, possibly, some linalyl. —J. O. B.

Sandalwood; Adulteration of Essential Oil of ——. Schimmel's Report, May, 1905, 70–71.

TWO samples of sandalwood oil in capsules have been found to be adulterated with castor oil. Steam distillation is an efficient method of detecting this sophistication; the residue thus obtained with genuine sandalwood oil, after 10 hours' distilling, was 8.6 per cent., compared with 26.76 and 22 per cent. with the adulterated samples. The residue of genuine sandalwood oil is soluble in all proportions in both light petroleum spirit and in 90 per cent. alcohol. Castor oil is insoluble in the former solvent, and any other fatty oil in the latter.—J. O. B.

Finland Pine Tar Oil, the so-called "Crude Oil of Turpentine." E. Sundwik. Schimmel's Report, May, 1905, 79, after Pharm. Centralh., 45, 859.

IN Finland, the essential oil of *Pinus silvestris* is obtained by dry distillation, as a by-product in the distillation of tar and other bodies. Although known there, and widely used for technical and medicinal purposes as "crude turpentine oil," it is quite distinct from the essential oil of turpentine, having an empyreumatic odour, and a more pronounced toxic action. The latter property renders it unsuitable for use as an antidote to phosphorus. It shows but slight reaction with iodine or chlorine, and does not absorb oxygen, since it contains much less pinene than true turpentine oil. It should be described as pine tar oil, and not as "crude oil of turpentine."—J. O. B.

Fagara Octandra; Essential Oil of the Wood of ——. Schimmel's Report, May, 1905, 82.

THE oil of the Mexican tree *Fagara octandra* Nat. C. Rutaceae, is yellow in colour, and has an odour of linalyl. Sp. gr. 0.922 at 15° C.; d_4^{20} +2° 30'; solubility in 90 per cent. alcohol, 2:1 becoming cloudy when more than 1.5 volume of solvent is added; ester value 6.09.—J. O. B.

Inula Gravolens; Essential Oil of ——. Schimmel's Report, May, 1905, 82.

THIS composite, common in the Mediterranean littoral, yields, on distillation, a brown oil with a greenish fluor

Sp. gr. 0.9754 at 15° C.; $n_D = -36^\circ 40'$; acid 8.45; ester value, 161.3; acetyl value, 239.8. Solubility in 70 per cent. alcohol 1:3 to 1:3.5 and more. Considerable separation of paraffin. From its odour would seem to contain bornyl acetate.—J. O. B.

Isia Citriodora; *Essential Oil of* —. Schimmel's Report, May, 1905, 83.

Light yellow oil of this Australian Myrtaceous as a similar odour to lemon-grass oil, but is more; sp. gr. 0.8972 at 15° C.; $n_D = +0$; it contains 15 per cent. of aldehyde, probably wholly citral; solubility in 70 per cent. alcohol 1:1.8 and more.—J. O. B.

Camphora; *Essential Oil from the Leaves of* —. Schimmel's Report, May, 1905, 83.

Colourless oil distilled from the leaves of the camphor growing at Cannes, has a pronounced cardamom odour, and closely resembles cardamom oil in properties. Yield 0.52 per cent.; sp. gr. 0.9058; $n_D = 15^\circ 54'$; acid value, 0.34; ester value, 8.82; acetyl value, 6.9; solubility in 80 per cent. alcohol 1:1, and more; under 4 mm. 35° to 95° C. The lower boiling fractions contain pinene and probably camphene. Cineol present in considerable quantity. The higher-boiling fractions contain levo-terpineol. This oil is quite different from any camphor leaf oil previously recorded.—J. O. B.

Mala; *Essential Oil of Fruit of* —. Schimmel's Report, May, 1905, 84.

Oil, closely resembling cardamom oil, obtained by distilling the fruit of this African Zingiberaceous plant at German East Africa, was brownish-yellow in colour, yield 0.76 per cent.; b. pt. (under 7 mm.), 51 to 52° C.; sp. gr. 0.9016 at 15° C.; $n_D = 16^\circ 54'$; acid value, 1.7; acetyl value 67.05; solubility in 70 per cent. alcohol 1:1 to 1:1.5, or more, with turbidity. Contained much cineol and terpineol.—J. O. B.

Hardwickia Binata; *Oleoresin of* —. Schimmel's Report, May, 1905, 85.

Oleoresin of the Indian Leguminous tree, known as "ikulavo oil," is reddish-brown, with a green odour and a peculiar odour. Sp. gr. 1.0021 at 15° C.; acid value, 96.15; ester value 12.31; insoluble in 80 per cent. alcohol. On steam distillation yields 44 per cent. of colourless oil, the residual being green and brittle. The essential oil has the following properties: $n_D = 7^\circ 42'$; acid value, 0.85; ester value, 2.88; solubility in 95 per cent. alcohol, 1:5 and more.—J. O. B.

Phyllanthus Polyantha, var. *Citrata*; *Essential Oil of the Leaves of* —. Schimmel's Report, May, 1905, 85.

Yield, 0.81 per cent.; colour, lemon yellow; sp. gr. 0.8904 at 15° C.; $n_D = 10^\circ 11'$; solubility in 80 per cent. alcohol, 1:1 and more; it contains aldehydes, pinene and citronellal.

Oil.—Yield, 5.42 per cent.; colour, bright yellow; sp. gr. 0.9042 at 15° C.; $n_D = 15^\circ 41'$; solubility in 70 per cent. alcohol 1:2.5 to 1:3. Citral appears to be the only aldehyde present, to the extent of about 30 per cent. was found in the non-aldehydic portion.—J. O. B.

FRENCH PATENTS.

Ureas [or *Pyrimidines*]; *Process for Producing Cyclic* —. E. Merck. Fr. Pat. 349,353, Nov. 8, 1904. Under Int. Conv., Nov. 12, 1903.

UREA, or one of its mono-alkyl or symmetrical dialkyl derivatives is condensed with cyanacetic esters in presence of an alkali amide, with or without some solvent such as xylene, with the formation of 4-imino-2,6-dioxypyrimidine or alkyl derivatives thereof. These compounds may be converted into the corresponding barbituric acids in the usual manner.—T. F. B.

Dialkylbarbituric Acids; *Process for Preparing* —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 349,320, Dec. 21, 1904. Under Int. Conv., March 18, 1904.

SEE U.S. Pat. 787,360 of 1905; this J., 1905, 559.—T. F. B.

GERMAN PATENTS.

Aldehydes, and Negatively Substituted Acetic Acids; *Process for Producing Condensation Products* [Perfumes] from Aliphatic —. E. Knoevenagel. Ger. Pat. 156,560, Dec. 16, 1902.

The condensation of aliphatic aldehydes with negatively mono-substituted acetic acids may be brought about by carrying out the reaction in presence of a quantity of ammonia or a primary or secondary amine insufficient to neutralise all the acid. It is stated that by this method 1 mol. of aldehyde may be condensed with one of acid to form acrylic acid derivatives, and with 2 mols. of acid to give glutaric acids. Ethylamine, diethylamine and piperidine are suitable amines for the process. The condensations of valeraldehyde and malonic acid (to β -isobutylglutaric acid) and of citral and cyanacetic acid (to citrylidene-acetic acid) by this means are described.—T. F. B.

Dextrin and Formaldehyde: Process for Preparing a Hard Compound of —, Soluble in Water, and which can be Pulverised. M. Busch. Ger. Pat. 155,567, April 12, 1903.

THE sticky product obtained by heating dextrin with formaldehyde solution may be converted into a hard substance, soluble in water, by drying *in vacuo*. The aldehyde appears to exist in a state of solid solution. Thus, by heating 1 kilo. of dextrin with 1.5 litres of 40 per cent. formaldehyde, a product is obtained containing 29.7 per cent. of formaldehyde. T. F. B.

Amides of Monobasic Acids: Process for Preparing Compounds of — with Formaldehyde. A. Einhorn. Ger. Pat. 157,355, June 20, 1902.

IN presence of acid condensing agents, formaldehyde and amides of monobasic aromatic acids condense to form diacyl-methylenediamines; but in presence of alkaline agents, such as sodium hydroxide or carbonate, compounds of the general formula: $\text{—R.CO.NH.C}_6\text{H}_4\text{OH}$, are obtained, where R represents an aromatic radical. On hydrolysis, formaldehyde is separated from these compounds. They are stated to be of use medicinally. —T. F. B.

Benzylamine Derivatives: Process for Producing Acylated —. A. Einhorn. Ger. Pat. 156,398, June 25, 1903.

THE methylol derivatives of acid amides described in Ger. Pat. 157,355 (see preceding abstract) may be condensed with various aromatic compounds (e.g., hydrocarbons, phenols, acids, &c.), in presence of acid condensing agents or zinc chloride, acylbenzylamines resulting; e.g., from *p*-nitrophenol and methylolbenzamide, *o*-hydroxy-*m*-nitrobenzylbenzylamine is obtained. These products are stated to be suitable as intermediate products for pharmaceutical and photographic preparations. —T. F. B.

Aldehydes: Process for Preparing —. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 157,573, Dec. 10, 1903.

ALDEHYDES are obtained by the interaction of equimolecular weights of formic acid or a formic ester and an alkylmagnesium halide. The following reaction takes place:—

XXII.—EXPLOSIVES, MATCHES, Etc.

Mercury Salts; Explosive —. K. A. Hofmann. Ber. 1905, 38, 1999–2005.

THE author has prepared *Chlorato-dimercuraldehyde*, $\text{ClHO.C:(Hg)HgClO}_3$, by direct reaction of an alcoholic solution of aldehyde on a solution of basic mercuric chlorate. The substance crystallises in shining prisms, which explode with great violence on the slightest mechanical disturbance or on contact with a flame or electric spark. It is too dangerously unstable to be used as a substitute for fulminating mercury. The corresponding *chlorotri-*

mercuroaldehyde, $\text{ClHO.C:(Hg}_2\text{O)HgClO}_3$ is readily prepared by leading acetylene into mercuric chlorate sol (or a mixture of mercuric chloride and sodium chlorate). It is less sensitive to shock than the first-described compound, but explodes violently in contact with flame. The similar *perchlorato*-compound is much more stable but its explosion when it does occur is equally violent not more so. In such compounds, the maximum explosive effect is attained when the carbon in the carbon-constituent is just sufficient to combine with the oxygen supplied by the other constituent; excess of carbon wasted, and weakens the effect. Compounds of pyridine with mercuric chlorate and perchlorate, $\text{HgR(C}_6\text{H}_4\text{N)}_2$ were also prepared, both explosive, though not sensitive to shock. By treating mercuric-potassium nitrite with acetylene, *nitrito-di-* and *tri-mercuroaldehyde* obtained, both explosive, though much less violent than the chlorate or perchlorate derivatives.—J. T. D.

Explosion of Collodion Cotton; Circumstances After an —, which occurred at the Factory of The I. & M. Co., at Edmonton, Middlesex, on March 7, 1905. By Captain J. H. Thomson, H.M. Chief Inspector of Explosives.

SOME 400 lb. of dry collodion cotton exploded in a stove, while it was being unloaded. The compartment from which the trays were being removed was fitted with brass angle pieces and on these the zinc bottoms of the trays slid. The ignition was without doubt due to friction between these surfaces, collodion cotton having been lodged on the brass angle pieces. The explosion in question is considered to be unique in that it is an instance of a really violent explosion of collodion cotton of low nitration (10.61 per cent. of nitrogen). It is suggested, as a preventative of such accidents in future, that sliding trays should be altogether done away with, that drying cupboards should not be used as they are difficult to clean out, and that all corners in which explosive dust can accumulate should be avoided. (See also this J., 1904, 560.)—G. W. McD.

ENGLISH PATENTS.

Guncotton Blocks; Method of and Apparatus for the Formation of —. G. W. Bell, Hayle, Cornwall. Eng. Pat. 10,663, May 9, 1904.

THIS guncotton pulp is fed into and subjected to pressure in a mould with a perforated end wall adapted to receive the guncotton, and allow the water to pass through. The mould becomes filled with guncotton which is forced into a block. Pistons are provided to compress the block endwise and the pulp may be fed through the pistons. The mould is provided with means for distributing the guncotton evenly. (See also this J., 1904, 882.)

—G. W. McD.

Dinitroglycerin; Manufacture and Use of —. Centralstelle für Wissenschaftlich-Techn. Untersuchungen. G. m. b. H., Neubabelsburg, Germany. Eng. Pat. 28,808, Dec. 29, 1904. Under Int. Conv., March 1, 1904.

TO obtain high yields in the manufacture of dinitroglycerol and to avoid as much as possible the formation of trinitroglycerol it is essential that the composition of nitrating acid and also the proportion between it and glycerol used should be very carefully regulated. Glycerol (100 parts) is allowed to flow, with constant stirring, at 18–20 °C., into an acid mixture (500 parts) consisting of sulphuric acid (67.5 per cent.), nitric acid (22.5 per cent.) and water (10 per cent.). No oily separation takes place in this case, or if so only to a very slight degree, in such small quantities as are separated out can be removed exclusively of trinitroglycerol which can be removed in the usual manner. The acid mixture (one part) in which all the dinitroglycerol is contained,

with water (10 parts) and the extracting agent; by this dilution, action of the acid on the extracting is avoided. The dinitroglycerol with the ether is used, and leaves an oily liquid on distillation, then purify the product it is dissolved in water, any trinitroglycerol remains undissolved. The solution is then extracted a second time, the ether agent distilled off, and the dinitroglycerol remains, dried. The acetyl and benzoyl esters of glycerol possess considerable gelatinising power on dextrin, &c., and can, therefore, replace nitrobenzene, camphor, &c., in the manufacture of powder, the freezing temperature of dinitroglycerol makes it useful as an addition to prevent trinitroglycerol explosion from freezing. (See also this J., 1904, 680.)

—G. W. McD.

Explosive; *New* — R. Imperiali, Naples, Eng. Pat. 3789, Feb. 23, 1905.

Explosive consists of barium nitrate (20 parts), potassium nitrate (40 parts), and picric acid (40 parts), these being finely powdered and intimately mixed. —G. W. McD.

UNITED STATES PATENTS.

Explosive Compound. A. E. Stanley, Ellinwood, Kansas. U.S. Pat. 789,943, May 16, 1905.

is made for an explosive compound comprising a mixture of corn meal, sulphur, glycerin, alcohol, saltpetre and potassium chlorate. —G. W. McD.

Explosive Composition — L. Thomas, Paris. U.S. Pat. 790,089, May 16, 1905.

claim is for an explosive compound consisting of glycerin having admixed therewith dinitrotoluene at 20° C., and obtained by nitrifying nitrotoluene, ether, cellulose and soda. —G. W. McD.

Starch Carbohydrates [Starch]; *Process of Making* — J. Hough, Dover, N.Y. U.S. Pat. 790,840, May 23, 1905.

It is introduced below the surface of a mixture of sulphuric acid and sulphuric acid containing an excess of sulphuric anhydride, the strength of the acid mixture such that a product containing about 16.5 per cent. nitrogen is obtained. During the nitration, further quantities of sulphuric anhydride are added to maintain the strength of the acid mixture at a practically constant level. The nitrated product is separated from the excess acid, washed, and rendered stable by treatment with solution of ammonia. —A. S.

XXIII.—ANALYTICAL CHEMISTRY.

INORGANIC—QUALITATIVE.

Phosphorus; *Detection of Yellow* — in *Phosphorus Sulphide*. L. Vignon. Comptes rend., 1905, 140, 9—1451.

SCHERLICH's method of distillation with water does not depend on the detection of phosphorus in the sulphide, for the sulphide itself, exhibits phosphorescence under these circumstances. Nor can phosphorus be detected by extraction with solvents, nor by observation of the green point under reduced pressure. If, however, a current of dry hydrogen be passed over the substance, a small proportion of free phosphorus causes the oxygen to exhibit phosphorescence in a dark room, and burn with a green flame, producing phosphoric acid, while the pure sulphide produces none of these effects. —J. T. D.

INORGANIC QUANTITATIVE.

Determination of Dust in Blast-Furnace — Hubendiek. Oesterr. Z. Berg.- u. Hüttenw., 1905, 1, 200; Chem.-Zeit., 1905, 29, Rep., 153.

proportion of dust in gas from blast-furnaces containing coke is 2—4 grms. per cb. m. in the case of solid

ores, and 4—6 grms. with loose ore, but only 1.5—2.5 grms. when charcoal is used. For use in gas analysis the gas is purified until it contains only 0.1 volume of dust per cb. m. To obviate the objection to the ordinary method of determining the dust, the author employs a double cone of 100 mm. diameter, the two necks of which are corked, while a circular piece of filter paper is fixed between the flanges of the two necks which come together at the middle of the vessel. The gas is drawn through this filter, all the dust collecting on the filter paper. The suction and measuring apparatus consists of two tubulated flasks, fitted with thermometers and graduated so that a volume of 5 litres can be measured. By connecting these flasks with each other and the filter, and altering their relative altitude, 5 litres of gas can be drawn through the filter at a time, so that about 200 litres of gas can be filtered in 30—60 minutes. A correction being made for the temperature and pressure of the gas, the filter is removed, and the collected dust is weighed after drying. —C. S.

Nitric Acid; *Analysis of* — R. Bensemann. Z. angew. Chem., 1905, 18, 816.

The sample is dissolved in water, and evaporated to dryness with twice its weight of oxalic acid; to the residue water is added, and the evaporation repeated. This is done from one to five times. The nitrate and chloride present are completely decomposed, the perchlorate and sulphate are not. The residue is now heated to redness in a platinum basin for some minutes, to decompose the perchlorate; it is then dissolved in water, and the solution made up to a known volume. In a portion of this the alkalinity (carbonate) is determined by titration; this corresponds to the nitrate and chloride originally present. A second portion is acidified with nitric acid, and titrated with silver nitrate; this gives the chloride corresponding to the original perchlorate. A third portion (or some of the original substance) is used for the determination of sulphate. The chloride is also determined in a portion of the original substance, and the nitrate is, of course, obtained by subtracting an amount equivalent to this chloride from the joint result given above. —J. T. D.

Lead; *Determination of* — by *Persulphate in Acid Solution*. M. Dittrich and A. Reise. Ber., 1905, 38, 1829—1831.

On adding to a solution of lead nitrate a 10 per cent. solution of ammonium persulphate, a white precipitate falls, which darkens on long heating on the water bath. It consists of an indefinite mixture of lead sulphate and peroxide, but the authors have never been able to attain complete conversion into peroxide. The precipitation of the lead is complete, however; and after five hours the liquid can be filtered, the precipitate washed with dilute solution of ammonium sulphate, and after burning off, converted completely into sulphate by evaporation with a drop or two of sulphuric acid. The addition of a little silver nitrate to the lead solution hastens the reaction, and allows filtration to be carried out three hours after precipitation (compare Marshall, Chem. News, 1901, 33, 76). This mode of precipitation is much more rapid and convenient than the usual precipitation by sulphuric acid and alcohol, and is equally accurate. No other metals are carried down with the lead. —J. T. D.

Arsenic; *New Method for the Determination of* — H. Cantoni and J. Chautems. Arch. Sc. phys. nat. Genève, 19, 364—366. Chem. Centr., 1905, 1, 1481.

The author finds that arsenic can be separated from antimony by making use of the volatility of methyl arsenite at the ordinary temperature. The solution containing the arsenic and concentrated hydrochloric acid is treated with methyl alcohol, and introduced into a 250 c.c. flask connected with a condenser, the other end of which dips into a flask containing sodium hydroxide solution and provided with a guard-tube. A current of dry air is then led through the apparatus through a tube reaching to within a few mm. of the surface of the arsenic solution. Under these conditions the whole of the arsenic is stated to be carried over into the sodium hydroxide solution, whilst any antimony present remains behind. —A. S.

Silicon in Iron: Determination of — D. F. Morgan. Eng. and Mining J., 1905, 79, 756.

For iron containing from 6 to 11 per cent. of silicon, 0.47 grm. of the sample is dissolved in 10 c.c. of sulphuric acid (1:3), and 15 c.c. of a solution containing 120 grms. of sodium chloride and 50 grms. of potassium chlorate per litre, are added. The solution is evaporated until sulphur trioxide fumes are evolved, and the heating continued for one or two minutes. After cooling, the residue is treated with hydrochloric acid (1:1), the solution boiled, filtered, and the residue washed with hydrochloric acid and water, ignited and weighed.

In the case of irons containing more than 11 per cent. of silicon, 0.235 grm. of the sample, 2 grms. of cuprous chloride, and 1 grm. of ammonium chloride are dissolved in 20 c.c. of sulphuric acid (1:3), and 15 c.c. of the solution of sodium chloride and potassium chlorate and 15 c.c. of water are added. The solution is evaporated until sulphur trioxide fumes are evolved, the residue treated with hydrochloric acid (1:1), and the solution boiled. The copper solution is then decanted on to a filter, leaving as much of the silica as possible in the beaker. A few crystals of oxalic acid are placed on the filter, and the latter washed with hydrochloric acid and water until free from copper. The residue in the beaker is treated with 2 grms. of oxalic acid and 50 c.c. of dilute hydrochloric acid, and the whole boiled, filtered through the same filter, and the silica washed with oxalic acid, hydrochloric acid and water, ignited and weighed. — A. S.

ORGANIC—QUALITATIVE.

Lactose, New Reaction for — A. Wochlk. Z. anal. Chem., 1904, 43, 670.

0.5 grm. of milk sugar is cautiously heated on the water-bath with 10 c.c. of 10 per cent. solution of ammonia, avoiding ebullition. In 10 to 15 minutes a madder-red colour appears in the solution. Other sugars when thus treated give, at the most, a straw-yellow colour. Owing to the shade of the colours produced, the reaction is not available for the detection of cane sugar in milk sugar. The spectroscopic characters of the red milk-sugar solution is quite distinct from those of other sugar solutions obtained in a similar manner. — J. O. B.

Saccharin, Detection of — in Beverages [Beer, Wine, etc.], Villiers, Magnier de la Source, Rocques and Payolle. Ann. Chim. anal. appl., 1904, 9, 418; from Rev. gén. Chim., 1904, 144.

The liquid, deprived of alcohol by evaporation or distillation, and if not already slightly acid, rendered so by the addition of 1 per cent. of acetic acid, is precipitated with excess of normal lead acetate solution; the excess of lead is removed as sulphate or phosphate and filtered off. The acid filtrate thus obtained is shaken out thrice in succession with half its volume of pure benzene. The benzene extract is partially distilled and the residue shaken with a small quantity of a 1:1000 solution of ferric chloride to determine the presence or absence of salicylic acid. Without removing the ferric chloride solution the rest of the benzene is then distilled off, the aqueous residue is acidified with sulphuric acid of 10 per cent. strength, warmed on the water-bath and treated with solution of potassium permanganate as long as the colour is discharged. This is preferably performed with the hot solution. In this way all salicylic acid, or aldehyde, or other bodies which may mask the taste or reaction of saccharin are destroyed. The liquid is again shaken out thrice with pure benzene, the benzene extract distilled or evaporated, and the residue taken up with 2 c.c. of water. One drop of this will give the sweet taste of saccharin. If the result is positive the rest of the liquid is transferred to a test tube, treated with 2 c.c. of caustic soda solution, sp. gr. 1.334, and evaporated to dryness. The tube is then attached to a thermometer, plunged into a fusible-metal bath and kept at 270° C. for three minutes. The fused mass is dissolved in 10 per cent. sulphuric acid, the solution shaken out with benzene, the benzene extract filtered and shaken with

5 c.c. of 1:1000 neutral ferric chloride solution. If charin be present, the characteristic violet salicylic acid reaction will be obtained. — J. O. B.

Lard from Cotton-seed Meal-Fed Hogs; Examination of — by Bömer's Phytosteryl Acetate Method. 1. M. Tolman. J. Amer. Chem. Soc., 1905, 27, 589. (See this J., 1904, 832.)

The author confirms Soltsien's statement that lard hogs which have been fed on cotton-seed meal do not contain phytosterol. Experiments with pure lard, beef tallow, mixtures of the same with both ordinary cotton-seed oil and cotton-seed oil which had previously heated, and also with different species of commercial lard, showed that lards which give the Halphen test because of added cotton-seed oil can be distinguished by Bömer's phytosteryl acetate test (this J., 1898, 954; 1901, 1147) from lards which give the test because the hogs had been fed on cotton-seed meal. An addition of even 2 per cent. of cotton-seed oil can be detected by the increase of the melting point of the cholesteryl (together with phytosteryl) acetate. Heated cottonseed oil which does not give Halphen's test can be detected by the phytosteryl acetate method. — S.

ORGANIC—QUANTITATIVE.

Beeswax; Determination of the Saponification Value — Schwärz. Z. oeffentl. Chem., 1905, 4, 19. Centralt., 1905, 46, 260.

Conx has stated that in the case of wax adulterated with paraffin, the saponification values obtained after boiling for three-quarters to one hour with N/2 alcoholic potassium solution are much too low. The author is unable to confirm this statement, and finds that one hour's boiling is sufficient to completely saponify even these adulterated waxes. In order to obviate any error, due to hydrolysis of the soap, when titrating back with aqueous N/2 hydrochloric acid solution, the previous addition of 30 c.c. of absolute alcohol is advised, or the N/2 acid may be used with alcohol instead of water. This precaution is specially needful when the cold saponification method in benzene solution is followed. — J. O. B.

Fusel Oil; Detection and Determination of — Takahashi. Bull. Coll. Agric., Tokyo, 1905, 6, 437. Chem. Centr., 1905, 1, 1483—1484.

The author has examined Komarowsky's method (this J., 1903, 1017, 1259), but finds that satisfactory results for fusel oil or isoamyl, isobutyl, propyl and isopropyl alcohols are given only by benzaldehyde, anisaldehyde and vanillin. From 4 to 6 c.c. of the liquid under examination are treated with 5—10 drops of a 1—2 per cent. alcoholic solution of benzaldehyde or anisaldehyde, and then about an equal volume of sulphuric acid is added. With benzaldehyde, a reddish coloration above a green layer is obtained, and with anisaldehyde a brown-yellow coloration changing to red, above two layers, the green changing to blue, and the other yellow changing to purple-brown and violet; if the liquid be shaken for some time a purple-red colour is obtained. When vanillin is used, 5 c.c. of a 1 per cent. alcoholic solution of the reagent are mixed with an equal volume of concentrated sulphuric acid. After the appearance of a yellow colour, the mixture is treated with an equal volume of the liquid containing fusel oil, when a blue coloration is produced. For the determination of the fusel oil, 10 c.c. each of the liquid containing it and of standard solutions of fusel oil are well mixed with 2 c.c. of a 1 per cent. alcoholic solution of anisaldehyde, and 20 c.c. of concentrated sulphuric acid added carefully. The colors produced are compared immediately after adding the acid, and also after 10 minutes from the time the mixtures are first shaken. — A. S.

Butter; Determination of Fat, Non-fatty Substance, and Water in — P. Soltsien. Chem. Rev. Fett-Ind., 1905, 12, 125.

ACETONE (b.pt. 56°—58° C.) extracts fat and water simultaneously from the butter. The weighed quantity (ob-

s.) of the sample is gently warmed in a weighed flask beneath a reflux condenser with 50 to 75 c.c. of a mixture in equal parts of acetone and absolute ether. The addition of the latter causing the non-fatty substances to separate more rapidly. After solution has taken place, an additional 10 to 15 c.c. of absolute ether are added, and the solution filtered through an ash-free filter, into a distilled distillation flask, after which the filter is washed out with 50 c.c. of the slightly warmed mixed solvent, and finally with about 25 c.c. of absolute ether. The residue in the distillation flask, in which some fragments of known weight are placed, is distilled on the water-bath to remove the acetone and ether, the flask is then opened, the water evaporated by heating the flask over a steam-bath, blowing air through, as in the determination of the Reichert-Meisels value, and the residue of fat dried until it is in weight. The residue of non-fatty substances in the original flask (and also the filter) is dried and weighed, and the water can then be calculated by difference.—C. A. M.

Formaldehyde [in Milk and Butter]; Colorimetric Method for the Detection and Determination of —. F. Bonnet, J. Amer. Chem. Soc., 1905, 27, 601—605.

The author makes use of the characteristic coloration, which changes from pink to dark blue, given by formaldehyde with morphine, for the detection and determination of formaldehyde.

Detection and Determination of Formaldehyde in Milk.—60 c.c. of milk are placed in a 3-in. evaporating dish, 1-in. watch-glass containing 1 c.c. of a solution of morphine sulphate in 100 c.c. of sulphuric acid (1:84) is floated upon the surface of the liquid. The dish is then covered with a 4 by 5-in. glass plate and allowed to stand at 20° C. With four parts of formaldehyde 100,000, a fairly good coloration was produced in 10 min. and with four parts per million, a slight coloration after 2½ hours. To determine the amount of formaldehyde, comparative tests are made, at the same time, with samples of milk containing known quantities of formaldehyde.

Detection of Formaldehyde in Butter.—A suitable quantity of the butter is spread upon the bottom of an evaporating dish, and the test carried out as in the case of milk.—A. S.

Formaldehyde; Study of Methods for the Determination of —. R. H. Williams. J. Amer. Chem. Soc., 1905, 27, 596—601.

The author has examined the different methods which have been proposed for the determination of formaldehyde in dilute solutions, he finds that the iodometric method is preferable, but when impurities are present, the potassium cyanide method should be used (see this J., 366). The results obtained by the potassium cyanide method are slightly lower than those obtained by the iodometric methods. For strong impure solutions of formaldehyde, the hydrogen peroxide method (this J., 79, 814) is the most satisfactory, but care must be taken to ensure complete oxidation, the time required being within limits, depending upon the concentration of the solution and the temperature. (See also this J., 1200.)—A. S.

Adrenalin; Colorimetric Determination of — by means of Iodine. J. E. Abelous, A. Soulié and G. Toujan. Comptes Rendus Soc. de biol., 1905, 301. Bull. Soc. Chim., 1905, 23, 624.

EXTRACTION of adrenalin is prepared so that 10 c.c. represent 1 mgrm.; to this 5 c.c. of N/10 iodine are added. After the lapse of an hour, a little starch paste is added and the color of iodine removed by sodium thiosulphate. At the moment when the iodine disappears, the blue tint is needed by a rose tint. The liquid is diluted to 50 c.c. and compared with the standard tint for 1 mgrm. of adrenalin. As the color fades on keeping, a standard can be made with a solution of litmus reddened with acid. For the assay of adrenal glands, 10 grms. are crushed with sand, and extracted with a 7 per cent. solution of common salt, heated at 40°—50° C. The liquid is rendered faintly acid with hydrochloric acid, boiled for a few seconds, filtered,

and made up to 150 c.c. Ten c.c. of this solution are treated with iodine as indicated above. The supernatant liquid of a sheep was found in this way to contain 1.17 mgrm. of adrenalin per gram.—E. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radio-Active Minerals. R. J. Strutt. Proc. Roy. Soc. London, 1905, A, 76, 88—101.

The author procured a series of radio-active minerals, had chemical analyses made, and determined the amounts of radium and of helium in them. He finds that the amount of radium in a mineral is proportional to the amount of uranium present; incidentally the hitherto unsuspected presence of uranium in monazite was brought to light. Thorium minerals, which vary greatly in radio-activity, were invariably found to contain the uranium-radium combination, which may possibly indicate that thorium is producing uranium. Helium was never found to occur in appreciable quantity except in presence of thorium; hence it seems probable that the helium of minerals is a product rather of thorium than of radium.—W. A. C.

Hydrate Theory of Solutions; Application to Electrolytes of the —. T. M. Lowry. Paper read before Faraday Soc., May 18, 1905. [Advance Proof.]

ACCORDING to the hydrate theory an aqueous solution consists of a mixture of hydrates in equilibrium with the solvent, and with one another. Further hydration leads to ionisation, the cause of which is looked for in the hydration of the ions. The author collates the evidence in favour of the hydrate theory of ionisation and also explains the conductivity of fused salts and mixtures of solid oxides, such as the Nernst filament, as due to the presence of positive and negative ionic complexes. In the discussion W. R. Bousfield mentioned that the evidence from the relation between freezing point depression and concentration, from the volume changes, and from the variations of ionic sizes with temperature and concentration all pointed to the increasing combination of solvent with solute as the dilution increased.—R. S. D.

Chemical Equilibrium; Determination of —, from Explosive Reactions. Fincke, Z. anorg. Chem. 1905, 45, 116—125. Nernst, *ib.*, 126—131.

THE authors have attempted to determine the amount of hydrogen peroxide formed during the explosion of hydrogen and oxygen, and of nitrogen dioxide formed during the explosion of hydrogen and air, varying the proportions of the reacting gases, and the pressure under which (and hence the temperature at which) the explosion occurs. Their results show that it is in general not possible, from the analysis of the cooled products after the explosion, to draw conclusions as to the composition of the mixture in chemical equilibrium at the moment of the explosion. In especial, it is certain that the amount of hydrogen peroxide present after the explosion of hydrogen with excess of oxygen is far less than that corresponding to equilibrium. It seems probable that where the explosive reaction is not too rapid, application of the principles of chemical kinetics may solve the problem, or perhaps measurement of the maximum pressure of explosion.—J. T. D.

Chromic Sulphate; Reaction of Green —, with Discontinuous Speeds. A. Colson. Comptes rend., 1905, 140, 1451—1453.

MEASUREMENTS of the heat of reaction of green chromic sulphate with potassium hydroxide show that it is isomeric with, and more easily decomposed than, the violet salt. If solutions of 1 mol. of the green salt and 1 mol. of barium chloride be mixed, barium sulphate, equivalent to the barium salt added, is precipitated in a very short time; but if the amount of barium chloride used be 3 mols., very little more heat is evolved, and very little more barium sulphate is precipitated at once than in the first case, and the liquid remains turbid for weeks. The reaction is not stopped, however, but retarded, for the quantity of barium chloride in solution gradually

diminishes. If the solution be boiled, the whole of the sulphate is precipitated. Or if, after adding to 1 mol. of the chromic salt 1 mol. of barium chloride, the precipitate be allowed to settle and a second molecule be then added, further precipitation occurs; and after the settling (slower than the first) of this precipitate, addition of a third molecule of barium chloride causes still more precipitate to be formed. The author considers that the reaction $(\text{SO}_4)_2\text{Cr}_2\text{SO}_4 + \text{BaCl}_2 \rightarrow (\text{SO}_4)_2\text{Cr}_2\text{Cl}_2 + \text{BaSO}_4$ occurs, and the chlorosulphate so formed ionises and reacts gradually so that

the latter salt now being able to react on more barium chloride. If a large excess of barium chloride is present in solution, however, the ionisation of the chlorosulphate is hindered, and further reaction is thus checked. (J. T. D.)

Cane-Sugar: Action of Metals on Solutions of —. R. Vondráček. Z. Zuckerind. Böhm., 1905, 29, 447—453.

FURTHER experiments confirm the author in his views concerning the mechanism of the catalytic action of platinum black (see this J., 1904, 388). It is shown that platinum black acts on cane-sugar solutions solely by means of the oxygen contained in it, which disappears if the action is continued for a long time. Measurements of the conductivity of a solution containing cane-sugar and platinum black and of the velocity of the inversion of the sugar, show that the latter is oxidised, forming compounds of an acid character. The inversion proceeds according to the logarithmic law.—T. H. P.

Enzyme and Ferment Action: Mechanism of —. H. M. Dawson. J. Inst. Brewing, 1905, 11, 288—307.

THE behaviour of enzymes in chemical change appears to correspond with the properties which characterise a catalytic agent, and, provided the conditions of the system be maintained constant, there seems to be no limit to the quantity of substance which a given small quantity of enzyme is capable of converting.

The phenomena of enzymic action are undoubtedly regulated according to the law of mass action, but owing to complicating factors the cases are not of the simplest order. It can no longer be held that the function of the enzyme in the reaction is simply one of contact, *i.e.*, that of imposing new conditions of a stimulating nature upon the system. The case of a simple unimolecular non-reversible chemical change which would occur if the action were merely one of contact generally only holds for a portion of the reaction. Recent work all tends to show that the enzyme combines with the substance on which it acts, to form an intermediate product which then splits up. The total change is then resolved into the resultant of two distinct component changes, each regulated by the fundamental law of mass action. But since the enzyme plays a part as one of the reacting substances, certain complex cases arise depending, for instance, on the affinity of the enzyme for the substance on which it acts, the proportion of enzyme present, the possibility of a decrease in the reacting portion of the enzyme as conversion progresses, affinity between the enzyme and the products of change and the possibility of equilibrium owing to the reversibility of the process. It has been found that the retardation of the action under the influence of the accumulated products depends on a relation between the stereochemical structure of the latter and that of the enzyme in the same manner as does the initial reaction. The phenomenon of hydrolysis by enzymes may be regarded as being effected by hydrogen ions, the enzyme forming a combination with the initial substance more sensitive to the action of these ions than the substance itself.—J. F. B.

Catalase. A. Bach. Ber., 1905, 38, 1878—1885.

THE author has studied the quantitative relations between catalase, prepared from the tissues of beef fat, and hydrogen peroxide, as the concentrations of the reacting substances were progressively increased. It was found that the

quantity of hydrogen peroxide decomposed increased with increase in the concentration of both reagents to maximum points, after which it remained constant. The complete exhaustion of the catalase, a certain concentration of hydrogen peroxide was necessary, and the complete decomposition of the hydrogen peroxide at certain concentration of catalase was required. The action of catalase follows the same law as that of pepsin and other ferments, *i.e.*, with excess of ferment action is directly proportional to the quantity of substance acted on, and with an excess of this the action is directly proportional to the quantity of ferment. The above relations are best expressed by the statement that the rate and quantity of substance acted on take part in the reaction in constant proportions, with the formation of intermediate compounds. As regards the velocity of the reaction between hydrogen peroxide and catalase, as the concentration of the latter was increased, it was found the velocity increased in a far greater measure than the concentration of the catalase.

In studying the relative distribution of hydrogen peroxide between catalase and peroxidase in a system containing catalase, peroxidase, hydrogen peroxide and oxidisable substance (pyrogallol) simultaneously, it was found that the presence of the catalase was entirely without influence upon the course of the oxidation. The circumstance is due to the fact that pyrogallol on paralyse the decomposing action of catalase on hydrogen peroxide.—J. F. B.

Oxydases: Further Observations on the —. K. Ueda. Bull. Coll. Agric., Tokyo, 1905, 6, 371—374. (Centr., 1905, 1, 1476—1477. (See this J., 1903, 1097.)

THE author is unable to confirm the statement of Claupe and Bach (see this J., 1904, 210) that the guaiacum reaction for peroxides is far more delicate than the potassium iodide-starch test. Ordinary commercial aldehyde contains an impurity, probably acetyl-hydrogen peroxide, which can be removed by treatment with sodium carbonate; this aldehyde produces a strong iodine reaction with the potassium iodide-starch reagent, whereas it does not react with guaiacum tincture. The guaiacum reaction is also a much less delicate test for nitrites than the potassium iodide-starch reaction. Most vegetable juices give a strong guaiacum reaction (oxydases), but no iodine reaction (nitrites). Experiments with faintly acid and alkaline solutions of potassium nitrite and asparagus and with faintly acid and alkaline aqueous extracts of *Sagittaria* buds indicate that the cause of certain vegetable juices, which are capable of liberating iodine, losing this property after heating, lies in the acidity of the juice and the presence of traces of amino compounds, since under such conditions nitrites are readily decomposed.

On treating the expressed juice of *Sagittaria* buds with 90 per cent. alcohol, washing the precipitate and taking it up in water, the solution gives the guaiacum reaction, but not the iodine reaction with the potassium iodide-starch reagent. The evaporation-residue of the alcoholic extract of the juice, on the other hand, gives only the iodine reaction, and the Griess reaction. The substance which gives the guaiacum reaction is thus not identical with that which liberates iodine from potassium iodide.—A.

UNITED STATES PATENT.

Luminous Composition. G. F. Kunz, New York. Pats. 789,811, and 789,812, May 16, 1905.

(789,811) CLAIM is made for a luminous composition consisting of a mixture of a substance containing radioactive or other radio-active material, a zinc compound such as willemite [$2\text{ZnO} \cdot \text{SiO}_2$], and a vehicle such as "oil," enclosed in a casing of rock crystal or other translucent substance.

(789,812). The composition consists of a mixture of a luminescent or radio-responsive material such as kieselguhr, a radio-active radium exciting material and a vehicle such as "oil," enclosed in a casing of rock crystal or other translucent substance.—A. S.

New Books.

DYNAMIK TECHNISCHER GASREACTIONEN. Sichen-
sungen von Dr. F. HABER, Professor an der
deutschen Hochschule, Karlsruhe i. B. R. Olden-
s Verlag, Munich and Berlin. 1905. Price

lume, containing 296 pages of subject matter,
illustrations. There is no alphabetical index
whole work, but a chapter of contents for each of
on Lectures. The subjects of these Lectures are
as:—I. Latent Heat of Chemical Decomposition,
Relation to the Energy of Reaction. II. Entropy,
Significance in Gas Reactions. III. Other Con-
es of Relationships established, besides Exposition
Connection with changes in Solid Substances.
amples of Reactions proceeding without change
number of Molecules. V. Examples of Reactions
ing with change of the number of Molecules.
mination of the Specific Heat of Gases. VII.
nation of the Equilibria of Gases, with Theoretical
chnical Considerations on kindred questions.

**UR ELECTRIQUE, son Origine, ses Transfor-
ns et ses Applications. Forces Naturelles,
o-Métallurgie—Chimie par Voie Sèche.** Par
E. MINET. Librairie Scientifique A. Hermann,
12, rue de la Sorbonne. Paris. 1905. Price

volume, containing 72 pages of subject matter,
raits, 49 illustrations, and 20 tables. There is also
of contents, but no alphabetical index. After
eneral Considerations," the principal subjects
of are as follows:—I. DESCRIPTIVE PART. The
Furnace of the Laboratory (1808—1886). Electro-
Igneous Fusion. Furnaces of different kinds.
THEORETICAL PART. UNITS AND PHYSICAL
UES. Mechanical Units. Electrical Units.
s of the Current. Power and Electric Work, &c.
TEMS AND ELECTRICAL CYCLES. IV. FUNDAMENTAL
F ELECTROCHEMISTRY.

Trade Report.

I.—GENERAL.

BUDAPEST; CHEMICAL TRADE OF — IN 1904.

Foreign Office Annual Series, No. 3381.

Imports of chemicals figure in the Customs returns of
ix for 1904 as follows:—

Chemicals.		Quantity.	
		1903.	1904.
.....	Cwts.	7,755	3,594
.....	Cwts.	1,613	1,802
es, nitrates, &c.	Tons	5,076	907
.....	Tons	13,707	1,289
s, tartrates, super- phosphates, &c.	Tons	18,817	22,062
manures	Tons	10,223	9,637
products	Tons	7,625	219
dyes	Cwts.	2,895	2,769
&c.	Cwts.	5,171	5,984

As above, the United Kingdom furnished, in 1904,
10,400 tons of sulphates, tartrates and superphosphates,
an increase from 1903 of 3225 tons, of which the largest item
was of sulphate of copper; some 1336 tons of
manures (a decline of 4026 tons); only 80 tons of
products, against nearly 7000 tons in 1903; and
10,000 tons of ink and colours.

The year 1904 was considered a very satisfactory one
by importers of copper sulphate, of which the total import
into France reached 29,657 tons. Of the 16,479 tons
landed at Bordeaux nearly all was of British origin. The
increase over the import in 1903 was due to the develop-
ment of the vines caused by a warm wet spring, which
encouraged the attacks of cryptogamic diseases. About
nine-tenths of the total sulphate of copper was used for
agricultural and viticultural purposes, the remainder
serving for wood injections and other industries. Prices,
which were high in the early months, gradually declined,
notwithstanding the increased demand, until July, when
they resumed an upward tendency which continued until
December. This was due principally to a rise in the price
of copper, but also in part to an active speculative demand
for forward deliveries during 1905. Trade was animated
and remunerative to merchants and promises satisfactory
results for the present year.

The following table shows the most important chemical
products exported in 1903—04:—

Articles.	Total.		United Kingdom.	
	1903.	1904.	1903.	1904.
Acids	Cwts. 18,223	Cwts. 21,402	Cwts. 9,932	Cwts. 9,139
Oxides	3,950	4,804	797	985
Salts, &c.	16,991	18,170	2,202	1,903
Acetate of copper	2,838	2,835	443	587
Glycerin	7,360	5,044	2,893	1,126
Kermes (mineral)	969	1,216	—	25
Wine lees	4,739	2,028	977	1,057
Crude tartar ...	32,974	1,907	5,094	1,038
Cream of tartar.	42,888	1,699	41,244	1,504
Superphosphate of lime	36,765	1,429	—	—
Chestnut and other tannin extracts	307,847	280,646	238,029	206,129

There was an increase in the export of gums in 1904 to
the extent of 4252 cwts., the total sent to all countries
being 25,744 cwts., of which 15,052 cwts. were taken by
the United Kingdom, showing a slight falling off on 1903.

Exports of resin and pitch in 1904 amounted to 335,419
cwts., an increase compared with 1903 of 39,685 cwts. The
United Kingdom was a purchaser to the amount of
135,093 cwts., an increase on 1903 of 90,353 cwts. Turpen-
tine exports were 48,214 cwts., a decline of 29,257 cwts.
Of the latter, British purchases were only 8,158 cwts.,
against 12,107 cwts. in 1903.

India-rubber and gutta percha exports amounted in
1904 to 17,176 cwts., of which 11,436 cwts. were sent to
the United Kingdom. This shows a decrease of 2,853 cwts.
in the general and 2662 cwts. in the British purchases.

Of pure olive oil the total exported was 27,472 cwts., a
slight increase from 1903. Exports of pure olive oil to the
United Kingdom amounted to 9486 cwts.

Groundnut or "Arachide" oil showed a falling-off in
the amount exported, the total sent to all countries being
26,761 cwts., which is less than the export in 1903 by
13,057 cwts. The United Kingdom purchased 12,875 cwts.
cwts., a decrease from 1903 of 6815 cwts.; of other
vegetable oils the total exported amounted to 12,315 cwts.,
which shows a slight increase on 1903. Next to no
business was done in these latter articles with the United
Kingdom.

Under the head of sugar, exports in 1904 amounted to
12,804 cwts. of raw and 89,585 cwts. of refined sugar, a
decrease as compared with 1903 of 13,835 cwts. in the
former and 1229 cwts. in the latter article. Exports to
the United Kingdom were 3208 cwts. of raw and
13,234 cwts. of refined, the former showing a slight
decrease and the latter an increase of 5061 cwts.

HOLLAND; CHEMICAL TRADE OF —.

Foreign Office Annual Series, No. 3391.

The following tables give details of imports and exports
of certain products from and to Holland during 1903 and
1904:—

Imports.

Exports—continued.

IV.—COLOURING MATTERS, Etc.

LOGWOOD EXPORTS FROM HAYTI.

Foreign Office Annual Series, No. 3385.

For the year ending September 30, 1904, 102,540,1 lb. of logwood and 51,920,567 lb. of root were shipped compared with 120,095,733 lb. of logwood and 48,368,408 lb. of root for preceding year. This shows a falling-off in export of logwood. The largest quantities were sent from Cape Hayti and Port de Paix. Most of the shipments went to the United States.

Only 4,982,502 lb. of guinea wood were exported against 10,378,452 lb. in the preceding year. The greater portion was shipped from St. Marc and Port au Prince.

ORCHIL: U.S. CUSTOMS DECISION.

Sulphonated orchil extract constituting a colour not employed in food products was decided to be dutiable at 30 per cent. *ad valorem* as a "colour," under paragraph 58 of the tariff. It was held neither to be "orchil" nor "orchil liquid," which are free under paragraph 62, as an article made from them.—R. W. M.

VII.—ACIDS, ALKALIS, Etc.

SULPHUR AND OTHER CHEMICALS IN SICILY.

Foreign Office Annual Series, No. 3396.

The shipments of sulphur during 1904 amounted to 508,980 tons, of which France took 115,897 tons and the United States and Canada 107,994 tons. The stock of sulphur in Sicily on December 31, 1904, was computed at 370,606 tons.

The quantity of sulphuric acid produced in Sicily in 1903 amounted to 5540 tons, of which 3500 tons were for export. The manufacture of superphosphates in the province of Messina amounted to 7500 tons. The province of Messina and Palermo produced 192 tons of sulphuric ammonia in 1903. There are 113 pumice stone quarries in Sicily, which in 1903 produced 8300 tons of stone. Exports in 1903 were 2544 tons, of which 368 tons went to the United Kingdom. During 1904 the principal ports from which asphalt was shipped were Syracuse (40,959 tons) and Mazzarelli, an open roadstead in the province of

Exports.

(34,583 tons). Some was also exported from the total exports of asphalt during 1901 and before, with the countries to which the asphalt was exported:—

Country.	Quantity.
	Tons
.....	1,600
Hungary	3,260
.....	700
Kingdom	7,877
.....	5,360
.....	40,522
.....	15,762
.....	1,279
.....	250
Total	79,610

Exports of sumach from Palermo during 1904 amounted to 36,388 tons, compared with 34,911 tons in 1903. The lentisco imported direct from Tunis amounted to 8179 tons.

POWDERED — : U.S. CUSTOMS DECISION. May 18, 1905.

Red calespar is dutiable at 20 per cent. *ad valorem* if manufactured article enumerated," under Section 1501. The assessment of duty at 2.25 dols. per "gypsum, calcined," under paragraph 9, was 1.—R. W. M.

CALAMINE : U.S. CUSTOMS DECISION.

May 8, 1905.

Calamine, assessed for duty at 20 per cent. *ad valorem*, under paragraph 183 of the tariff, is free of duty as "calcined under paragraph 514. The importation of calamine with the native carbonate and hydrated silicate of iron of which are understood by metallurgists to be included by the term calamine.—R. W. M.

IX.—BUILDING MATERIALS, Etc.

CEMENT AND CHALK IN DENMARK.

Foreign Office Annual Series, No. 3392.

Production of cement in Denmark during 1904 was 209,000 barrels of 470 lb. each, or 282,000 tons, by five mills. A considerable part is exported to the United Kingdom and to transatlantic ports, where cement has acquired a very good repute.

Export of raw chalk to Germany, Sweden, Norway, and Scotland was the same as in 1903, the value about 11,000*l*. The whole production was about 400,000 tons, and from this amount about 74,000 tons, or 40%, was exported. Pulverised chalk to the value of about 1625 tons, value 1200*l*., was also exported.

Another export article is flint pebbles used in cement. Considerable quantities of these round stones have been found on the coasts of Denmark, especially on the coast of Langeland.

X.—METALLURGY.

TASMANIA; MINERAL PRODUCTION OF —.

Bd. of Trade J., June 1, 1904.

The following table, compiled by the Government of Tasmania, shows, as far as can be ascertained, the quantities of metals and minerals raised in Tasmania in the years ending September 30 and December 31,

September Quarter, 1904. December Quarter, 1904.

	Quantity	Value.	Quantity	Value.
	Ozs.	£	Ozs.	£
Gold, fine	16,755	71,170	17,804	75,624
	Tons		Tons	
Silver lead ore	14,237	58,301	11,871	52,265
Blister copper	2,044	138,685	2,016	142,004
Copper ore			61	1,329
Native copper			212	11,116
Tin ore	869	66,798	872	70,157
Iron ore	2,000	800	1,900	750
Coal	20,800	17,757	12,562	10,678
Flux ore	3,133	1,524	2,180	933
Wolfram ore			15	1,117
Bismuth ore			6	15
Total value	—	355,721	—	76,309

From the quarterly reports it appears that the total value of metals and minerals raised in the year 1904 was 1,509,847*l*., as compared with 1,354,044*l*. in 1903, an increase of 155,803*l*.

NEWFOUNDLAND; MINERAL EXPORTS OF —.

Bd. of Trade J., June 1, 1905.

The following particulars of the mineral exports from Newfoundland in the year ended June 30, 1904, compared with the preceding year, are taken from the report on the Colony recently issued by the Colonial Office:—

	1902-3.	1903-4.
	Dols.	Dols.
Barytes	1,840	6,878
Copper ore	378,041	403,971
Iron ore	692,825	526,285
Pyrites	167,439	311,162
Slate	57,700	39,850
Total	1,297,845	1,288,146

The exports went chiefly to the United Kingdom, the United States and Canada. The United Kingdom took in 1903-04, 199,086 dols. worth of copper ore, 56,575 dols. of iron ore, and 38,750 dols. of slate, as compared with 207,228 dols., 92,935 dols. and 57,700 dols. respectively in 1902-03. The exports to Canada included 209,000 dols. worth of iron ore in 1903-04, against 313,780 dols. in 1902-03. The exports to the United States comprised, in 1903-04, 204,885 dols. worth of copper ore, 63,680 dols. of iron ore, and 311,162 dols. of pyrites, against 170,813 dols., 92,660 dols., and 159,549 dols. respectively in 1902-03.

The exports to Holland consisted entirely of iron ore to the value of 197,030 dols. as compared with 188,250 dols. in 1902-03. There were no mineral exports to Germany in 1903-04.

COPPER IN HONDURAS.

U.S. Cons. R.p., No. 2261, May 18, 1905.

A rich discovery of copper is reported to have been made recently in the department of Yoro, in Honduras; the ore is said to run from 15 to 60 per cent. copper. Eight well-defined veins have been located, which can be traced for miles on the surface; two of these are 12 ft. wide, one 10 ft., and one 14 ft. It is calculated that the entire body will average 50 per cent. copper. The properties are surrounded by forests of oak and pine, a coal deposit within 20 miles, abundant water power sufficient for any machinery needed for reduction, &c., and it is comparatively close to transportation—40 miles from the Ulua River, which is connected by canals with the bay at Puerto Cortes, from which point there is daily communication with the United States.

XII.—FATS, FATTY OILS, Etc.

GREASE; SOLUBLE — : U.S. CUSTOMS DECISION.

May 18, 1905.

The United States Circuit Court decided that a soluble grease made from tallow and sulphonated is not dutiable

at 30 per cent. *ad valorem*, as "alizarin assistant," under paragraph 32 of the tariff, but at 20 per cent. *ad valorem*, under Section 6, as a "manufactured article, unenumerated." The article in question is used to soften the cloth after the application of the dyestuffs. R. W. M.

XIII. A.—PIGMENTS, PAINTS, Etc.

OXIDE OF IRON PAINT: U.S. CUSTOMS DECISION.

May 3, 1905.

Paint containing 92 per cent. of oxide of iron is dutiable at 30 per cent. *ad valorem* as a "crude colour," under paragraph 58 of the tariff. The claims of the importer for assessment under paragraph 19 as "crude sienna earth" at 1 c. per lb., or at 40 c. per ton, under paragraph 121, were overruled. The evidence showed that the article had been washed and calcined, and was in fact a crude paint. R. W. M.

GREEN EARTH: U.S. CUSTOMS DECISION.

May 29, 1905.

"Green earth," of a greyish-green tint, used as a base for lime proof greens with aniline colours, is not dutiable at 30 per cent. *ad valorem* as a "colour or pigment" under paragraph 58 of the tariff, but at 2 dols. per ton as a "wrought or manufactured earth," under paragraph 93. The testimony showed that it was used as a base in paint making, and not as a pigment to impart colour. R. W. M.

XIII. C.—INDIA-RUBBER, Etc.

FACILE: U.S. CUSTOMS DECISION.

May 16, 1905.

Assessment of duty at 20 per cent. *ad valorem* as a "manufactured article unenumerated" under Section 6 of the tariff was affirmed on india-rubber substitute made from oils. The claim of the importer for free entry under paragraph 573 as "india-rubber" was overruled. R. W. M.

XIV.—SUGAR, STARCH, GUM, Etc.

SUGAR: THE COST OF —.

A return relating to the cost of sugar has been prepared by the Board of Trade and published as a Parliamentary paper (174). It shows the price per lb. retail of the kind of sugar most largely consumed by the working classes, whether refined or unrefined, on or about March 1, 1905, in the capital cities of Germany, Austria-Hungary, Belgium, France, Holland, Russia, Denmark, and Great Britain respectively, together with the amount, in English currency, of the existing Customs and Excise duties respectively per lb. in each case. It is explained that it is not to be understood that the prices given refer to a uniform grade of sugar in the various capitals:—

Country and Capital City.	Retail Price.	Customs Duty.	Excise Duty.
	d. per lb.	d. per lb.	d. per lb.
Germany—			
Berlin	2½	1.02*	0.76
Austria-Hungary—			
Vienna	3½	1.08*	1.72
Budapest	3½		
Belgium—			
Brussels	3½	1.11*	0.87
France—			
Paris	3½	1.44*	1.18½
Holland—			
Amsterdam†	4½	2.45‡	2.45
Russia—			
St. Petersburg	4½	1.22	1.23
Denmark—			
Copenhagen	2½	0.73	0.27
Great Britain—			
London	2½	0.45	—

* In the cases of Germany, Austria-Hungary, Belgium and France, imported sugar is subject to excise duty in addition to import duty proper. The "Customs duty" stated above for these countries includes the total amount of duty payable on importation—i.e., it includes both import and excise duty.

† In the case of Holland, imported sugar is subject to excise duty only.

‡ Amsterdam has been taken instead of the Hague.

§ Including also the "taxe de raffinage," levied equally on imported sugar and on sugar of home production.

XV.—BREWING, WINES, SPIRITS, Etc.

PERFUMERY ALCOHOL TAX: U.S. CUSTOMS DECISION.

May 8, 1905.

The British alcohol tax accruing on alcohol contained in perfumery is held to be an element of market value and subject to the *ad valorem* duty of 45 per cent. Although the British tax is not paid on the merchandise since it is exported, the open market rather than value in bond is taken as the basis for assessing duty. R. W. M.

FERMENTS: U.S. CUSTOMS DECISION.

May 16, 1905.

"Assorted ferments" have to pay duty of 20 per cent. *ad valorem* as "manufactured articles unenumerated." The claim of the importers for free entry as a "vitae of drug" under paragraph 548 was overruled. R. W. M.

XX.—FINE CHEMICALS, Etc.

CITRUS INDUSTRY OF SICILY.

Foreign Office Annual Series, No. 3396.

During the 1903-04 season it was calculated that Italy produced 5,250,000,000 of citrus fruit, or an average of 750,000,000 over the preceding season. To this production Sicily contributed 3,652,800,000, or than half of the production of all Italy.

The harvest for the season 1903-04 in Sicily by province was as follows:—

Province.	Number
Messina	1,125,000.
Palermo	1,005,000.
Catania	800,000.
Syracuse	465,000.
Trapani	174,000.
Caltanissetta	30,000.

Out of 16,700,000 citrus fruit trees in all Italy, 10,390,000 accounted for 10,390,000. On an average each tree is calculated to produce 352 fruits.

A good quantity of essence of lemon is produced in Palermo and all along the eastern coast of Sicily. lemon, oil of orange (both bitter and sweet), oil of dard and oil of cedrat are produced in various parts of the northern and eastern coasts.

Calcium citrate is produced at Palermo, Messina, Catania. Efforts are being made to create a combination in this article.

Citric acid has hitherto been produced by the Solfatara method. At Palermo a new combination has been found under the title of "La Citrica" for the production of citric acid by a method due to a Sicilian called Restuccia, whose process is said to be a modification of one covered by F. Arrosto in 1834. It remains to be seen whether the Restuccia method is a commercial success.

CAMPHOR IN JAPAN.

Foreign Office Annual Series, No. 3387.

Refined camphor steadily increased in price from 12s. to 9½. 12s. per 100 lb. at the beginning of 1904 to 12½. 16s. to 14½. 10s. at the end of December. The high prices have provoked a demand by American refiners for an increased import duty of 6 c. gold (3d.) per lb. on refined camphor, so that, at present prices with that duty, Japanese refined camphor would have but a poor chance.

Although the export of crude camphor was not on a large scale as in 1903, prices did not advance as they might have done. The Government have allotted a larger quantity for home consumption, but the increased quantity is still far from satisfying the home demand, which is chiefly for the manufacture of tablets for medicinal purposes. The export of these tablets to a certain extent interferes with the operations of refiners abroad, who find difficulty in competing with the Japan-made tablets, owing to labour being cheaper there.

The quality of the camphor has become more and more

pply was much less than had been estimated. Estimate was 36,000 piculs (4,788,000 lb.) from Java and 13,000 piculs (1,729,000 lb.) from Japan; actual receipts were 41,000 piculs (5,453,000 lb.) from Java and 6,000 piculs (798,000 lb.) from Japan; piculs (864,500 lb.) were refined in Japan for export, chiefly to India, the United States and Canada. Bulk goes to India.

CHRYSAOBIN; U.S. CUSTOMS DECISION.

May 17, 1905.

United States Circuit Court decided that chrysaobin is not dutiable at 25 per cent. *ad valorem* as a medicinal preparation "under paragraph 68 of the tariff act at 1 cent per lb. and 10 per cent. *ad valorem* under paragraph 20, as a "drug advanced in value." The court followed a previous decision on gaulthol, in which it stated that the substance in question was not a medicinal preparation in the form in which it was imported, and hence medicinal preparation"—R. W. M.

Patent List.

In these lists, [A.] means "Application for Patent," and [C.S.] means "Complete Specification Accepted."

A Complete Specification accompanies an Application, and is annexed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals of acceptance. The Complete Specifications are advertised. The Specifications thus advertised as accepted are open to opposition at the Patent Office immediately, and to opposition in the courts within six months of the said dates.

LANT, APPARATUS, AND MACHINERY.

- 5,204A (1904). Macquesten. Method and apparatus for separating solid particles from each other. June 9.
- 1,206. Johnson (Feld). Apparatus for subjecting gases or vapours to the action of liquids. May 29.
- 1,393. Stubbs. Apparatus for heating or cooling fluids, also applicable for condensing steam or other vapours. May 31.
- 1,438. Meeredy. Method and apparatus for drying and pulverising liquid or semi-liquid substances. May 31.
- 1,686. Saatmann. Drying and absorbing apparatus. June 3.
- 1,708. Greaves. Furnaces. June 5.
- 1,724. Hargreaves. Evaporating solutions. June 5.
- 1,776. Clark. Apparatus for promoting the absorption or solution of substances by liquids, suitable (*inter alia*) for use in the purification of illuminating and other gases. June 5.
- 11,941. Reed. Condenser. June 7.
- 11,957. Dreyfus, Meyenberg, and the Clayton Aniline Co., Ltd. Apparatus for filtering or separating liquids from solids or matters from impurities, and for analogous operations.* June 7.
- 12,114. Hellström. Liners for centrifugal liquid separators. [Appl. in Sweden, June 14, 1904.]* June 9.
- 12,201. Soest. Drying drums.* June 10.
- 12,300. Forster. Crucible furnaces. June 13.
- 12,533. Barthelmes. See under II.
- 13,227 (1904). Lennox. See under XVII.
- 13,481 (1904). Sulman and Picard. Removal of precipitates from liquids. June 15.
- 13,638 (1904). Dewar. Method of absorbing gases and the application thereof to the production of high vacua and the separation of gases. June 15.

- [C.S.] 15,761 (1904). Groll. Furnaces. June 7.
- " 17,625 (1904). Small and Friction. Engine Packing Co., Ltd. Separator and filter for mixed liquids. June 21.
- " 19,565 (1904). Hanberg. Feeding arrangement for centrifugal separators. June 7.
- " 20,319 (1904). Van Westerbork. Safety tanks or vessels used in filtering or for other purposes. June 7.
- " 4332 (1905). McNeil. Apparatus for separating liquids from vapours. June 15.
- " 5761 (1905). Holmes. Apparatus for washing and scrubbing gases. June 7.
- " 7168 (1905). Newton (Worthington). Apparatus for cooling or evaporating liquids. June 15.

II.—FUEL, GAS, AND LIGHT.

- [A.] 11,281. Drury and Pulman. Producing a combustible charge from oil, alcohol, or other liquid. May 30.
- " 11,372. Hills. Manufacture of gas and apparatus therefor. May 31.
- " 11,373. Hills. Enrichment of gas for illuminating, heating, or power purposes. May 31.
- " 11,413. Assmann. Process for preparing compressed gas for power purposes. [Ger. Appl., June 4, 1904.]* May 31.
- " 11,657. Hutchins. Gas producer. June 3.
- " 11,681. Hennequin and Cayeux. Combustible liquids for explosion motors. June 3.
- " 11,725. Goskar and Burn. Suction gas producer plants. June 5.
- " 11,751. Moores and Bailey. Manufacturing air gas.* June 5.
- " 11,758. Wakefield. "Flue" lights. June 5.
- " 11,776. Clark. See under I.
- " 11,859. Marriott and Darch. Agglutinants for artificial fuel and the like. June 6.
- " 11,929. Heinrichsdorff. Conversion into gas and superheating of liquid fuel.* June 7.
- " 11,940. Galley and Hutton. Apparatus for mixing gases for heat, light, and power. June 7.
- " 11,949. Just, Haumann, and Verein. Electricitäts Act-Ges. Manufacture of incandescent filaments for electric lamps. June 7.
- " 11,956. Woodall and Duckham. Vertical retorts for the carbonisation of coal.* June 7.
- " 12,059. Moore and Livens. Gas producers.* June 9.
- " 12,160. Evano. See under XI.
- " 12,251. Kiderlen. Gas generator.* June 13.
- " 12,289. Woodall and Duckham. Vertical retorts for the carbonisation of coal.* June 13.
- " 12,468. Delage. Manufacture of and method of heating by radio-incandescent bodies. [Fr. Appl., Oct. 26, 1904.]* June 15.
- " 12,516. Noll and Trainer. Manufacture of briquettes from fuel, ores and the like. [Ger. Appl., Sept. 14, 1904.]* June 16.
- " 12,533. Barthelmes. Method of and apparatus for purifying blast furnace gases, dust-laden air and the like, and for dissolving gases and other matter in liquids.* June 16.
- " 12,563. Wilson. Gas producers. June 17.
- [C.S.] 9608 (1904). Whitfield. Gas producer plant. June 7.
- " 13,253 (1904). Crawford. Manufacture of filaments for incandescent electric lamps. June 21.
- " 13,822 (1904). Whittaker, and C. Whittaker and Co. (1900), Ltd. Manufacture of peat fuel and apparatus therefor. June 21.
- " 14,288 (1904). De Valerioli, Sepulchre, and Moeller. Manufacture of incandescent mantles. June 7.
- " 15,846 (1904). Spencer. Gas regenerative furnaces. June 15.
- " 17,906 (1904). Zuiderhoek. Process for the manufacture of coke briquettes. June 21.
- " 3154 (1905). Woltmann. Artificial fuel. June 7.
- " 5761 (1905). Holmes. See under I.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 11,893. Macalpine, Sunnace and Abady. Refining petroleum and mineral oils. June 6.
 „ 11,998. Leatherbarrow. Method of treating pitch. June 8.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 11,196. Newton (Bayer and Co.). Manufacture of anthraquinone derivatives. May 29.
 „ 11,205. Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters.* May 29.
 „ 11,739. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of amino-hydroxylated derivatives of phenylnaphthimideazole. June 5.
 „ 12,144. Johnson (Badische Anilin und Soda Fabrik). Reduction of indigo and similar colouring matters. June 15.
 [C.S.] 16,268 (1904). Abel (Act.-Ges. f. Anilinfabr.). Manufacture of sulphur dyes and of materials for their production. June 15.
 „ 17,274 (1904). Shillito (Aniline Colour and Extract Works, formerly J. R. Geigy). Manufacture of azo colouring matters. June 7.
 „ 17,318 (1904). Ransford (Cassella and Co.). Manufacture of sulphine colours. June 15.
 „ 19,165 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters and intermediate products. June 21.
 „ 19,174 (1904). Murray (Bask Chem. Works). Manufacture of indoxyl, its homologues or their derivatives. June 21.
 „ 7835 (1905). Johnson (Dye Works, formerly Durand, Huguenin & Co.). Manufacture of leuco-galloyaniline dyes. June 21.
 „ 7839 (1905). Lake (Oehler). Production of blue mono-azo dyes. June 15.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 11,294. Hasselmann. *See under IX.*
 „ 11,410. Mackey. Means or apparatus for purifying dye-water and similar effluent. May 31.
 „ 11,417. Matthey and Campbell. Means for recovering solvents from wool and other substances. May 31.
 „ 11,577. Moeller. Dyeing cotton, any vegetable, animal, artificial fibres and wool or materials composed of such fibres. June 2.
 „ 11,617. Wohle. Method of degumming ramie, rhea, or other fibre. June 2.
 „ 11,987. Young and Hardman. Bleaching vegetable fibres in the raw or manufactured state. June 8.
 „ 12,169. Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging pastes for use in the discharge of dyed textile fabrics.* June 10.
 „ 12,277. Cathelineau and Fleury. *See under XIX.*
 „ 12,278. Cathelineau and Fleury. *See under XIX.*
 [C.S.] 13,227 (1904). Lennox. *See under XVII.*
 „ 16,798 (1904). Hulme. Printing calicos and other woven fabrics. June 7.
 „ 17,152 (1904). Howorth (Soc. Franc. de la Viscose). Apparatus for the manufacture of artificial silk. June 21.
 „ 17,330 (1904). Mitchell. Process of removing grease from cotton waste. June 21.
 „ 20,178 (1901). Johnson (Badische Anilin und Soda Fabrik). Manufacture of discharging pastes for the discharge of dyed textile materials. June 21.
 „ 20,633 (1904). De Naeyer. Apparatus for dyeing or bleaching textile materials. June 21.
 „ 2873 (1905). Greenwood. Mechanism for dyeing wherein the material to be dyed is continuously submerged within the dye without exposure to the atmosphere during the dyeing process. June 15.
 „ 6726 (1905). Baudot. Scouring, washing and like machines. June 21.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

- [C.S.] 18,096 (1904). Abel (Act.-Ges. f. Anilinfabr.). Process of dyeing leather. June 21.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 11,180. Wetter (J. D. Riedel, Akt.-Ges.). *See under mercury.** May 29.
 „ 11,300. Cie. Thermo-Electrique (Système Hermite) Soc. Anon. Manufacture of copper sulphide thermo-electric couples. [Fr. Appl., Apr. 25, 1905.]* May 30.
 „ 11,347. Thompson (Goldschmidt and Polzer). Manufacture of white lead, oxides of lead, a mixture of the latter with white lead.* May 30.
 „ 11,539. Brake. Carbonic acid gas production apparatus. June 2.
 „ 11,986. Garroway. Manufacture of sulphuric acid and glauber salts. June 8.
 „ 12,021. Bloxam (Soc. Anon. d'Etudes Chimiques). Manufacture of lead peroxide. June 8.
 [C.S.] 16,504 (1904). Woltereck. Production of ammonia. June 7.
 „ 4762 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of dehydrated carbonates of alkalis. June 7.
 „ 6885 (1905). Deutsche Gold- und Silber-schneid-Anstalt vorm. Rössler. Manufacture of sodium perborate. June 15.
 „ 9875 (1905). Morgan Crucible Co., Ltd. Manufacture of stratified blue plumbago. June 21.
 „ 11,300 (1905). Cie. Thermo-Electrique (Système Hermite) Soc. Anon. Manufacture of copper sulphide for thermo-electric couples. June 21.

VIII.—GLASS, POTTERY, AND ENAMEL.

- [A.] 11,723. Thornton, Sharp, and Ingle. Kilns for firing colours in glass, earthenware, enameled &c., supplied with a self-burning mixture of carburetted air. June 5.
 „ 12,107. Pilkington. Manufacture of plate or glass and apparatus therefor. June 9.
 „ 12,122. Cowper-Coles. Process of enameling metals. June 10.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 11,191. Braschler-Kurtz. Method of treating asphalt and like substances. [Ger. Pat., June 2, 1904.]* May 29.
 „ 11,294. Hasselmann. Chemically impregnating wood and other textile or fibrous substance or preventing putrefaction, rot, or fungus.* May 30.
 „ 11,594. Eccles. Treatment of wood for rendering it inflammable. June 2.
 „ 11,696. Carr and Urwin. Manufacture of fire bricks and other fireclay goods. June 3.
 „ 11,807. Bruce. Manufacture of cement. June 6.
 „ 12,105. Meyenberg. Insulating material and process for preparing the same.* June 9.
 [C.S.] 12,664 (1904). Fitzsimons. Preparation for laying dust on roadways, &c. June 7.
 „ 16,657A (1904). Butterfield. Composition for coating roads, pipes, walls, and other surfaces. June 21.
 „ 16,940 (1904). Müller and Jarek. Heat non-conducting material. June 21.
 „ 19,737 (1904). Boulton (Hülsberg und Co.). Impregnation of wood and other porous materials. June 21.
 „ 25,787 (1904). Michell. Manufacture of non-conducting coverings, blocks and slabs suitable for covering steam pipes, boilers, &c. June 7.

- 5,788 (1904). Michell. Manufacture of non-conducting coverings, blocks and slabs, suitable for covering steam pipes, boilers, &c. June 7.
 76 (1905). Singer. Composition for laying and absorbing dust. June 7.
 457 (1905). Armstrong. Manufacture of Keen's or other cements having a gypsum base. June 21.

X.—METALLURGY.

- 1,268. Brayshaw. Process of hardening high speed steel. May 30.
 1,334. Boulton (Cheswright). Alloys. May 30.
 1,335. Boulton (Cheswright). Nickel steel alloys. May 30.
 1,572. Atkinson. Preliminary treatment of refractory ores. June 2.
 1,681. Plumer. Hardening and tempering copper or its alloys.* June 3.
 1,793. Swinburne. Treatment of sulphide and other metallic ores. June 5.
 1,833. Fyfe. Ore roasting furnaces and means for producing and depositing fumes from ores. June 6.
 2,001. Auchinachie. Extracting gold from sea water. June 8.
 2,122. Cowper-Coles. *See under VIII.*
 2,200. Haddan (Fellner und Ziegler). Process of treating finely granulated or pulverised ores. June 10.
 2,320. Greenawalt. Roasting furnaces.* June 13.
 2,516. Noll and Trainer. *See under 11.*
 2,582. Rock. Process for the recovery or separation of gold and other metals from sea water. June 17.
 1,123 (1904). MacArthur. Treatment of ores containing antimony. June 15.
 2,347 (1904). Steuart. Apparatus for the extraction of metals from their ores. June 7.
 2,816 (1904). Brayshaw. Melt or bath for hardening steel. June 15.
 3,121 (1904). Nicholas. Treatment of zinc ores. June 15.
 11 (1905). Gayley. Method of smelting ore. June 7.
 194 (1905). Baggaley and Allen. Smelting sulphide ores. June 15.
 589 (1905). King, and Advertising Mirrors Co. Solder or flux whereby ordinary solder can be used to solder aluminium. June 21.

ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- 11,353. Luckow. Process for regenerating electric accumulators.* May 30.
 1,407. Tenber. Electric heating apparatus.* May 31.
 11,654. Schauschiff. Accumulator plates. June 3.
 11,861. Hubbell. Battery plates.* June 6.
 11,862. Hubbell. Battery plates.* June 6.
 12,160. Eveno. Electro catalytic process for obtaining fixed gases from any suitable carburant. June 10.
 12,221. Hepburn. Electrolytic apparatus. June 13.
 12,253. Kelly. Accumulator plates. June 13.
 12,291. Classen. Electrolytic production of lustrous metallic coatings upon metals.* June 13.
 12,454. Cowper-Coles. Electrodeposition of copper and other metals. June 15.
 13,579 (1904). Cowper-Coles and Co., Ltd., and Cowper-Coles. Deposition of metals or metallic compounds upon metals or metallic articles. June 21.
 14,958 (1904). Potthoff. Solutions for the electrodeposition of metals. June 7.
 28,434 (1904). Billwiller and Karrer. Electric insulating material and process of manufacturing the same. June 7.
 2313 (1905). Rosworth. Electric furnaces. June 15.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

- [A.] 11,444. Marchado da Cruz and Cardoso. Candles.* May 31.
 „ 11,679. Hennequin and Cayeux. Lubricants.* June 3.
 „ 11,950. Zonca. Devices for recovering waste oil.* June 7.
 „ 12,525. De Hemptinne. Process for eliminating the odour of fish oil. June 16.
 [C.S.] 17,218 (1904). Armstrong, Armstrong and Armstrong. Manufacture of soap and detergent compounds. June 15.
 „ 27,105 (1904). Lockell. *See under XX.*
 „ 1292 (1905). De Sales. Process of manufacturing soap. June 15.
 „ 7646 (1905). Buchanan. Apparatus for heating linseed oil with driers. June 15.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A).—PIGMENTS, PAINTS.

- [A.] 11,347. Thompson (Goldschmidt and Polzeniusz). *See under VII.*
 „ 11,782. Moysc. Method of protecting metallic construction against oxidation. June 5.

(B).—RESINS, VARNISHES.

- [A.] 12,460. Wachendorf. Manufacture of varnishes for producing mat surfaces. [Ger. Appl. April 3, 1905.]*

(C).—INDIA-RUBBER.

- [A.] 11,371. Hill and Leeson. Vulcanising rubber solution. May 31.
 „ 11,574. Perkin, and Whipp Bros. and Todd, Ltd. Manufacture of materials more especially for use as substitutes for india-rubber and gutta-percha. June 2.
 „ 11,575. Perkin, and Whipp Bros. and Todd, Ltd. Manufacture of a material more especially intended for use as a substitute for india-rubber and gutta-percha. June 2.
 [C.S.] 2655 (1905). Steenstrup and A. S. Gummi-Regenerations Societet. Process for de-vulcanising india-rubber. June 15.
 „ 8378 (1905). Gregory and Thom. Process for reclaiming waste vulcanised india-rubber. June 24.

XIV.—TANNING; LEATHER, GLUE, SIZE, Etc.

- [A.] 12,210. Thompson. Process for treating and utilising the spent bark of tan pits. June 13.
 „ 12,266. Trenckmann. Manufacture of parchment like skin. [Ger. Appl. Oct. 3, 1904.]* June 13.
 [C.S.] 12,388 (1904). Tollis. Tanning of hides into leather. June 7.
 „ 18,511A (1904). Amend. Bating, de-acidifying and oxidising of hides and skins. June 7.
 „ 19,244 (1904). Sonoff and Zwerckoff. Curing skins and hides. June 15.

XVI.—SUGAR, STARCH, GUM, Etc.

- [A.] 11,838. Wetter (Weinrich). Process for purifying masse-cuite syrups or impure sugar solutions. June 6.
 [C.S.] 10,664 (1904). Ewen and Tomlinson. Process for converting wood cellulose into sugar. June 21.
 „ 16,262 (1904). Börner. Manufacture of starch-like or amyloid-like substances and sugar. June 15.
 „ 16,546 (1904). Stein and Loewenthal. Manufacture of sugar. June 7.

- [C.S.] 16,546A (1904). Stem and Loewenthal. Manufacture of milk. June 7.
 .. 3972 (1905). Schuler. Process and apparatus for producing crystals from sugar solutions and the like. June 15.

XVII.—BREWING, WINES, SPIRITS, Etc.

- [A.] 11,117. Barker, Ronnberg and Co.). Manufacture of a product which enables beer to be hopped in a rational, economical manner.* May 29.
 .. 11,153. Hahn and Reiser. Method for the production of dry yeast.* May 31.
 .. 11,171. Dewar. Melting apparatus. June 1.
 [C.S.] 12,117 (1904). Storrer. Production of non-deposit beers and stouts for bottling. June 7.
 .. 13,227 (1904). Lemnox. Evaporator for evaporating the liquid in brewers' wash, sewage, waste or spent dyes and the like, and concentrating the solids in the same. June 21.
 .. 16,992 (1904). Baker and Lang. Sulphuring of hops, malts and other materials with special reference to the avoidance of contamination with arsenic and apparatus therefor. June 7.
 .. 17,651 (1904). Linzel and Bischoff. Process for the production from fermented liquid of a drink free from alcohol, by means of a vacuum. June 21.

XVIII.—FOODS; SANITATION, WATER PURIFICATION; & DISINFECTANTS.

(A.)—FOODS.

- [A.] 12,095. Heritte. Method of preserving organic substances. June 9.
 [C.S.] 2048 (1905). Schon. Apparatus for treating milk and like liquids to reduce the globules of cream or fat to a state of fine sub-division. June 15.
 .. 6617 (1905). Jones. Composition for making aerated beverages. June 21.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 11,410. Mackey. *See under V.*
 .. 11,431. Walker. Destruction of noxious or poisonous fumes or gases in blasting operations in mines or the like. May 31.
 .. 12,092. Swallow, Swallow and Fillburn. Composition for purifying sewage and other foul waters. June 9.
 .. 12,481. Spivey. Treatment of sewage, trade effluents, and other foul or polluted waters. June 16.
 [C.S.] 12,540 (1904). Casimir Rez et ses Fils. Means for preventing incrustation in steam generators. June 15.
 .. 13,227 (1904). Lemnox. *See under XVII.*
 .. 13,436 (1904). Vial. Water clarification. June 7.
 .. 13,588 (1904). Henderson. Treatment of sewage. June 21.
 .. 17,690 (1904). Bramby. Utilisation of a waste product for the treatment of boiler feed water. June 21.
 .. 17,920 (1904). Mather and Platt, Ltd., and Hepburn. Method of and means for softening water. June 15.
 .. 1776 (1905). McLean and Paterson. Process of treating and utilising sewage. June 21.
 .. 5200 (1904). Guttman. Apparatus for purifying or softening water. June 7.

XIX.—PAPER, PASTEBOARD, Etc.

- [A.] 11,165. Hawke. Printing papers. May 29.
 .. 11,166. Hawke. Writing papers. May 29.
 .. 11,179. Hawke. Manufacture of printing paper. June 1.
 .. 11,180. Hawke. Manufacture of writing paper. June 1.
 .. 11,512. Béal. Manufacture of celluloid.* June 1.
 .. 12,085. Zwick and Zwick. Process of preparing proofing paper, &c. June 9.
 .. 12,277 and 12,278. Cathelineau and F. Plastic transparent product for the manufacture of fibres, films, plates, or blocks, and preparing the same. June 13.
 .. 12,413. Binns. Manufacture of paper. Appl. June 15, 1904.* June 15.
 .. 12,523. Erkens. Paper making machines.* June 16.
 [C.S.] 10,664 (1904). Ewen and Tomlinson. *See under XVI.*

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 11,219. Ellis (Merck). Manufacture of carbaturic acids. May 29.
 .. 11,926. Lieber. Method of making radium substances. [C.S. Appl., July 30, 1904.]* June 7.
 .. 12,292. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of salts of *p*-aminobenzoic ether. June 13.
 .. 12,526. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of preparations of pepsin containing hydrochloric acid. June 16.
 [C.S.] 18,825 (1904). Newton (Bayer und Co.). Manufacture of a pharmaceutical compound. June 15.
 .. 27,105 (1904). Loebell. Process for preparing oils and fats containing iodine and sulphur. June 21.
 .. 10,976 (1905). Merck, Merck, Merck and Co. Manufacture of guanines from cyanamide, 6-diamido-6-oxypyrimidine and its homologues. June 15.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

- [A.] 11,239. Schaak. Production of collotype plates. [Ger. Appl., May 31, 1904.]* May 29.
 .. 11,452. Mercier. Means for developing photographic images.* May 31.
 [C.S.] 17,192 (1904). Strasser. Chrome-gelatine process of photography. June 7.

XXII.—EXPLOSIVES, MATCHES, Etc.

- [A.] 11,431. Walker. *See under XVIII. B.*
 [C.S.] 15,053 (1904). Cocking, and Kynoch, Ltd. Smokeless powders and their manufacture. June 15.
 .. 6651 (1905). Haddan (Roth). Explosives containing aluminium or other light metals. June 1.

XXIII.—GENERAL ANALYTICAL CHEMISTRY.

- [C.S.] 18,047 (1904). Haber. Process of and means for testing the composition of gaseous mixtures. June 15.

JOURNAL OF THE Society of Chemical Industry.

A RECORD

FOR ALL INTERESTED IN CHEMICAL AND ALLIED MANUFACTURES.

ISSUED TWICE A MONTH.

No. 13.—Vol. XXIV.

JULY 15, 1905.

No. 13.—Vol. XXIV.

Subscription of Members 25 - per annum;
Entrance Fee 21 -;
Election by the Council.

Price to Non-Members 30 - per annum;
To Members 25 - per Set of extra or back numbers.
Single copies (Members and Subscribers only)
1882—1901, 2 6 each; 1902 *et seq.* 1 9 each.

Society of Chemical Industry.

Past Presidents:

Henry E. Roscoe, B.A., D.C.L., LL.D., Ph.D., F.R.S.	1881—1882.
Frederick A. Abel, Bart., K.C.B., F.C.V.O., D.C.L., D.Sc., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
H. Perkin, LL.D., Ph.D., F.R.S.	1884—1885.
K. Muspratt	1885—1886.
David Howard	1886—1887.
James Dewar, M.A., LL.D., F.R.S.	1887—1888.
Ludwig Mond, Ph.D., F.R.S.	1888—1889.
Lowthian Bell, Bart., F.R.S.	1889—1890.
Kilder Cook	1890—1891.
Emerson Reynolds, M.D., F.R.S.	1891—1892.
John Evans, K.C.B., D.C.L., LL.D., F.R.S.	1892—1893.
C. C. Stanford	1893—1894.
E. Thorpe, C.B., LL.D., Sc.D., Ph.D., F.R.S.	1894—1895.
Thomas Tyrer	1895—1896.
Edward Schunck, Ph.D., F.R.S.	1896—1897.
Frank Clowes, D.Sc.	1897—1898.
George Beilby	1898—1899.
F. Chandler, D.Sc., M.D., Ph.D., LL.D. Jos. W. Swan, D.Sc., M.A., F.R.S.	1899—1900.
Ivan Lewinstein	1900—1901.
W. Ramsay, K.C.B., D.Sc., LL.D., F.R.S. A. H. Nichols, M.Sc., M.S., LL.D., D.Sc.	1901—1903. 1903—1904. 1904—1905.

† Deceased.

LIST OF COUNCIL, 1905—1906.

President: Dr. Edw. Divers, F.R.S.

Vice-Presidents:

Backeland.	Dr. J. Lewkowitsch.
Carl Bell.	N. H. Martin.
Ed. Colbentz.	Max Muspratt.
Dr. R. E. Hodgkinson.	Dr. Wm. H. Nichols.
David Howard.	T. J. Parker.
Ivan Lewinstein.	Sir Wm. Ramsay, K.C.B., F.R.S.

Ordinary Members of Council:

Dr. Dunn.	Dr. K. E. Markel.
Ed. Guttman.	B. E. R. Newlands.
Ed. Langway.	Prof. W. J. Pope, F.R.S.
Dr. R. Lang.	Sir Boverton Redwood.
Dr. R. Lang.	Walter F. Reid.
Dr. Arthur.	Dr. W. S. Squire.

Sectional Chairmen and Secretaries:

BIRMINGHAM.	
Dr. F. Frankland, F.R.S.	F. R. O'Shaughnessy.
CANADIAN.	
Dr. Smale.	Alfred Burton.
LIVERPOOL.	
Dr. Carey.	W. Roscoe Hardwick.
LONDON.	
Dr. G. Salomon.	Julian L. Baker.
MANCHESTER.	
Dr. Bailey.	Julius Hübner.
NEWCASTLE.	
Dr. Louis.	F. C. Garrett.
NEW ENGLAND.	
Dr. Howard.	Dr. W. H. Walker.
NEW YORK.	
Dr. Sell W. Moore.	Dr. H. Schweitzer.
NOTTINGHAM.	
Dr. Paton.	S. R. Trotman.
SCOTTISH.	
Dr. Merry.	Dr. Thos. Gray.
SYDNEY, N.S.W.	
Dr. Liversidge, F.R.S.	T. U. Walton.
YORKSHIRE.	
Dr. R. Procter.	Thos. Fairley.

Honorary Treasurer:

Samuel Hall, East London Soap Works, Bow, E

Hon. Foreign Secretary:

Dr. Ludwig Mond, F.R.S.

General Secretary:

Charles G. Crosswell, 59, Palace Chambers, Westminster, S.W.

THE JOURNAL.

Publication Committee:

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

CONGRESS OF CHEMISTRY AT LIEGE.

In connection with the Liège Exhibition, a Congress of Chemistry and Pharmacy will be held from the 27th to the 30th July next. By a subscription of 10 francs, members may take part in the Congress, and will receive a copy of the transactions. Application for Adhesion Forms and programmes should be made at once to M. J. Raymond, Pharmacien, Liège, or M. J. Wauters, Chimiste-adjoint de la Ville de Bruxelles.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

List of Members Elected.

July 10th, 1905.

Alpass, James, c/o The Clayton Aniline Co., Ltd., Clayton, Manchester, Secretary.
Collett, John H., Hillfield, Gloucester, Chemical Manufacturer.
Delal, Vasanji Premji, Dwarkadas Building, Hornby Road, Fort, Bombay, Lecturer on Chemistry, Elphinstone College.
Danker, Fred. E., 1, Atlantic Street, South Boston, Mass., U.S.A., Salesman, Oakes Manufacturing Co.
Dolan, H., "Duness," Grappenhall Road, Stockton Heath, Warrington, Chemist.
Duggan, Edward J., The Charles E. Sholes Co., 164, Front Street, New York City, U.S.A., Vice-President.
Ernst, C. A., Lansdowne, Pa., U.S.A., Chemist.
Lewis, F. W., Aetna Powder Co., Room 1718, Tribune Building, Chicago, Ill., U.S.A., Secretary.
McKerrow, W. J., c/o J. C. & J. Field, Ltd., Lambeth, S.E., Analytical Chemist.
McLellan, Basil G., c/o Rowntree & Co., Ltd., The Cocoa Works, York, Analytical Chemist.
Morgan, Jerome J., Scandia, Warren County, Pa., U.S.A., Teacher.
Nichols, W. H., jun., 25, Broad Street, New York City, U.S.A., President, San Carlos Copper Co.
Palmer, Dr. Charles S., c/o *Engineering and Mining Journal*, 505, Pearl Street, New York City, U.S.A., Associate Editor.
Raschig, Dr. F., Ludwigshafen a. Rhein, Germany, Manufacturing Chemist.
Sellers, George E., Rock View, Milnsbridge, near Huddersfield, Aniline Colour Maker.
Teepie, Dr. J. E., Industrial Laboratories, Easton, Pa., U.S.A., Director.
Waters, C. D., c/o Morrison & Carr Paper Co., Tyrone, Blair Co., Pa., U.S.A., Chemist.
White, Clarence B., 25, North Mountain Avenue, Montclair, N.J., U.S.A., Chemist.
Zinkeisen, Oscar T., 15, Cortlandt Street, New York City, U.S.A., Importer of Chemicals.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they temporary or permanent. Multiplication of addresses also to be avoided as tending to create confusion. Sending subscriptions, the use of the form attached the application helps in the verification of addresses which the safe delivery of the Journal depends.

Birthday Honour List.

His Majesty has been pleased to confer a Baron upon Mr. Samuel B. Boulton; and the honour of Knighthood upon Dr. Boverton Redwood and Col. Samuel Sadler, M.P.

PROCEEDINGS

OF THE

TWENTY-FOURTH ANNUAL MEETING.

LONDON.

MONDAY, JULY 10TH, 1905.

Twenty-fourth annual general meeting of the Society was held in University College, Gower Street, on Monday, July 10th, the President, Dr. Wm. H. Diver, occupying the chair.

Among those present were Dr. E. Divers, F.R.S. (President Elect), Sir Henry E. Roscoe, F.R.S., Dr. Perkin, F.R.S., Mr. E. K. Muspratt, Dr. L. Mond, Dr. J. Emerson Reynolds, F.R.S., Mr. Thos. Tyrer, J. F. Chandler, and Sir Wm. Ramsay, K.C.B., (Past Presidents); Dr. L. Baekeland, Dr. Virgil L. Ziegler, Prof. W. R. Hodgkinson, Messrs. E. Grant, Max Muspratt, T. J. Parker, Dr. F. B. Power (Residents), Dr. J. Grossmann, Messrs. Oscar Reisch, Hemingway, Ling, Dr. K. E. Markel, Prof. Pope, F.R.S., Sir Boverton Redwood, Mr. W. F. R. W. S. Squire (Ordinary Members of Council), Gordon Salamon (Chairman, London Section), Lillian L. Baker (Hon. Sec. London Section), Mr. Wightman (Treasurer, London Reception Committee), Mr. E. Carey (Chairman, Liverpool Section), Roscoe Hardwick (Hon. Sec., Liverpool Section), H. Bailey (Chairman Elect, Manchester Section), Julius Hübner (Hon. Sec., Manchester Section), T. Dunn (Chairman, Newcastle Section), Mr. Howard, (Chairman, New England Section), Dr. W. Moore (Chairman, New York Section), Dr. H. L. H. (Hon. Sec., New York Section), Mr. R. C. Cook (Hon. Treasurer, New York Section), Mr. J. T. Chairman, Nottingham Section), Mr. S. R. Trotman Sec., Nottingham Section), Mr. T. Fairley (Hon. Yorkshire Section), Mr. Samuel Hall (Hon. Sec. of the Society), Mr. Theo. Armstrong, Mr. Barry, Dr. Chas. Baskerville, Messrs. V. G. E. A. Byrnes, A. A. Claffin, Dr. W. A. Converse, Dreyfus, Miss Mary Lynn, Dr. H. A. Metz, Mr. Nichols, Dr. Maximilian Toch, Dr. Ida Welt, Dr. Viley, Mr. J. Bernays, Dr. Chas. A. Keane, Mr. J. Dr. L. T. Thorne, Prof. H. E. Armstrong, F.R.S., A. S. Calder, Mr. R. Forbes (Carpenter, Dr. B. Dyer, O. Forster, F.R.S., Mr. S. K. Muspratt, Mr. F. Sutton, Dr. W. A. Tilden, F.R.S., and Major-General J. Waterhouse, F.R.S.

PRESIDENT, in opening the proceedings, called upon Gordon Salamon, Chairman of the London Section, for a few words of welcome to the meeting.

GORDON SALAMON said that he had been asked by his colleagues to convey to the President, and to all those who crossed the Atlantic with him, their keen delight in meeting them amongst them; and also, in the name of the British Sections, to give them a hearty welcome, and to express the feelings of the British members from every point of view. They were delighted to have an American President for the Society, and especially to have the experience they had some time ago under the presidency of Dr. Chandler. Also, they held their ship with their American brethren in very great esteem, but, above all, they felt that the appearance of many of their friends from America was good evidence that the Society was going to be cemented for many years, and he hoped for all time. As representative of the interests of the Anglo-Saxon race in applied chemistry, they were proud to know that the continuity of development and progress of the Society was in every way assured.

PRESIDENT, on behalf of the Society, thanked Gordon Salamon and the English members for the cordiality

of their welcome. He did so from the bottom of his heart because he knew it came from the heart, and on that account was all the more appreciated. It was most difficult to express the feeling of appreciation which he and his associates from the other side of the Atlantic had of the magnificent reception which had been accorded them.

The GENERAL SECRETARY (Mr. C. G. Crosswell) then read the minutes of the twenty-third annual meeting, held in New York, on September 8th last, which were confirmed.

On the motion of Dr. H. W. Wiley, seconded by Dr. W. H. PERKIN, F.R.S., Dr. Wm. Dreyfus and Prof. W. R. E. Hodgkinson were appointed scrutineers of the ballot papers.

REPORT OF COUNCIL.

The SECRETARY then read the Report of the Council as follows:—

The number of members on the register is 4326 as compared with 4134 at the last Annual Meeting. During the year 452 members have been elected, as compared with 400 last year; the losses have been 260, as against 216 and there have been 41 deaths, as compared with 29 last year.

The names of the deceased members are as follows:—Wm. Ackroyd, Wm. Allen, Sir I. Lowthian Bell, G. A. Bicknell, J. Lloyd Bullock, John Campbell, Wm. Chittaway, J. F. Wyllie Clarke, W. Martyn Cook, P. Coward, Sir J. Neilson Cuthbertson, Fred Lall Dey, T. H. Dodd, Prof. T. M. Drown, John Dunn, C. D. Ekman, J. L. Ferrell, Jas. Foster, Jos. Glatz, F. A. Goodhue, Prof. E. B. Kenrick, Wm. J. Kent, J. G. McArthur, J. K. Mackenzie, F. M. Mercer, Dr. H. Salvin Pattinson, Archibald Pearson, F. G. du Pont, T. A. Pooley, Dr. A. B. Prescott, H. A. Rademacher, W. H. Richmond, Sir B. Samuelson, Geo. Shaw, Wm. R. Shaw, E. Seel, John Storar, T. T. P. Bruce Warren, Dr. C. Otto Weber, G. N. Williamson and F. G. Worth.

The JOURNAL for 1904 numbered 1252 pages, equal to 52.2 pages per issue, as against 57.5 in 1903. During the past session 92 original papers, with discussions, have appeared in the JOURNAL, as compared with 90 in the previous session. Of 17 papers returned to authors by the Publication Committee for amendment or condensation, 12 have been published after having been recast, rewritten or condensed, and five have been withdrawn.

The Hon. Treasurer's financial report was issued in the JOURNAL for June 30th and will be laid before the meeting.

The Council, on behalf of the Society, wish to express their very hearty appreciation of the exceedingly cordial welcome given to the Society by the New York Section on the occasion of the last Annual General Meeting, a welcome which was confirmed in every city visited in the United States, and it takes this opportunity of expressing the pleasure it now has in the visit of members of the New York, New England, and Canadian Sections.

In the autumn of 1904, the President requested Dr. Edw. Divers, F.R.S., to act as his deputy during his year of office. Whilst hearty thanks are due to Dr. Divers for his unremitting services in that capacity, a special welcome is offered to the President himself on his arrival in this country.

The Council has had the pleasure of congratulating its late President, Sir Wm. Ramsay, K.C.B., F.R.S., on having been awarded one of the Nobel Prizes, and its thanks are due to him for the manner in which he represented the Society during the visit to America.

The agreement with Messrs. Eyre and Spottiswoode for printing and publishing the JOURNAL terminated at the end of 1904, and a new contract, for three years, has been entered into with Messrs. Vacher and Sons, of Westminster. This involves some increased cost. The thanks of the Council are due to the Hon. Treasurer, Mr. David Howard, and Mr. R. E. R. Newlands, for their services in connection with the negotiation of the new contract.

The postage of the JOURNAL reaches the considerable sum of £550 a year; and enquiry is being made as to the possibility of joint action with other Learned Societies with a view to obtain some reduction on the rates of postage of Scientific Journals.

Since the last Annual Meeting, a New England Section has been constituted, covering the States of Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, and Vermont. The inaugural meeting of the new Section, at which the President and many members of the New York Section were present, to give it encouragement and support, was held on May 12th. The Birmingham Section has also been revived.

Last August, the Chancellor of the Exchequer appointed a Departmental Committee, which included our members Sir Wm. Crookes, F.R.S., Dr. T. E. Thorpe, C.B., F.R.S., and Mr. Thos. Tyrer, to enquire into the existing facilities for the use, without payment of duty, of spirits in arts and manufactures, and in particular into the operation of Section 8 of the Finance Act, 1902. By permission of the Controller of H.M. Stationery Office, the report, with its appendices, was published in the Society's JOURNAL on April 29th, 1903, and, in reply to a letter of thanks from the Council, the Chancellor of the Exchequer stated that it was his intention to propose legislation during this session of Parliament to carry out the recommendations of the Committee.

The Council has placed on record its appreciation of the persistent efforts of Mr. Thomas Tyrer in the cause of Industrial Alcohol, and has tendered him its thanks for his services on the Committee.

In this connection it may be stated that the Spirit Committee of the Society, the Chemical Sections of the London, Manchester, and Bury Chambers of Commerce, the Drug Club, the Auto-mobile Club, the Society of Motor Manufacturers and Trades, and the West India Committee, all co-operated in obtaining evidence to be laid before the Alcohol Committee.

Dr. VIRGIL CORLENTZ moved the adoption of the Report, which was seconded by Dr. BAEKELAND and carried unanimously.

THE TREASURER'S REPORT.

The Hon. TREASURER (Mr. Samuel Hall) read his Report as follows:—

It is my pleasant duty, as your Treasurer, to report on the finances of last year, 1904, and to give some indications of the probable condition of the present year.

The statement of "Income and Expenditure" for 1904 is in the 30th June number of our JOURNAL, as is also the Hon. Treasurer's account with the Society at 31st December, 1904.

The salient points, as compared with 1903, on the receipt side are £4,814, being an increase of £200 from subscribing members—naturally we have no annual receipts from members who have compounded, except in the form of dividends on accumulations.

Entrance and life composition fees amount to £472 and show an increase of £50. This money is always invested and does not reckon as ordinary income. The accumulations, as you will notice, are all in first-class securities, and are in the names of three trustees. They amount to £14,124 stock, giving a yearly income of £443, or £3 28. 8d. per cent. duty paid.

Sales of the JOURNAL are £509 and are almost exclusively from non-members (but not at a lower price); this shows the appreciation of the JOURNAL by the outside world. Altogether, the amounts make an available income of £5,776.

Turning to the other side of the account, 5000 copies cost for publishing, £1064; Editorial expenses, £1533. Your Publication Committee meet twice monthly and give their very careful attention to the work, having corrected the slip proofs which have been sent them. These items of publishing and editorial work together cost in 1904, £2597, or £120 less than in 1903. Annual and Sectional Meetings cost £584, an increase of £160. Salaries, £30 more, office expenses £70, the cost of enlarging the Council Room having been paid in 1903.

The result enabled us to give £100 to the National

Physical Laboratory, to devote £212 towards the Decennial Index for 1896-1905, which we hope to complete in 1906, and left a balance to the good of £1117 4s. During 1904, £1000 was invested, and £1000 has invested this year, coming into the accounts of 1905.

The following is the Auditors' Certificate on the Account of December 31st, 1904. The securities the same in both accounts, and the balance practical

"We have compared the above statement with vouchers, counterfoils of the receipts issued and records, and are of opinion it correctly exhibits cash transactions of the Society for the year. The amounts of the Metropolitan 3 per cent. solidated Stock, 3 per cent. New Zealand and cent. New South Wales Stocks have been confirmed by the Chief Accountant to the Bank of England. Certificates for the remaining investments have been inspected and the Bank balances have been certified to us by the Bankers.

"(Signed) MALL, WILKINS, RANDALL & Co., Chartered Accountants."

This is very satisfactory for 1904, but you must give the credit to your Hon. Treasurer, it belongs wholly to our late President, Mr. Levinstein, who in the twice monthly JOURNAL and made the contract our late printers; at that time we thought advertisement would have paid better than it appears to have. I still hope that it may be increased to the advantage of the Society, both in money and usefulness.

As foreshadowed in last year's Report, our late President having the option, terminated the three years' agreement at the end of 1904. To continue the work they now terms involving so much extra cost, that we could not accept them, and were obliged to obtain tenders elsewhere; from among several, we selected that of Messrs. Vacher and Sons, and have contracted with the three years certain, at a considerably greater cost than in 1904, but equally considerably less than our old printers required.

From this it is clear that unless made up in other ways—more members, advertisements, &c.—we cannot expect to put by as much in the next three years as we have done in the last three.

Though this may make your Treasurer have to lay a tight hand in some things, speaking from my personal knowledge of the Council and its individual members, the primary idea of us all is that the JOURNAL must not only be kept up to its present position, but to the highest standard for information and promptness.

The Publication Committee are always glad of new and useful papers read before the Society; if too long they hardly receive their proper attention from the readers; it is, therefore, desirable for their authors' sake to keep them as terse as possible; this may also assist the Society and your Treasurer, as every page has to be paid for *pro rata*.

I also wish to lay emphasis on our rule that for the two months, January and February, numbers of the JOURNAL are sent to all Members whether they have paid the year's subscription or not. If the subscription has been received by the end of February, the 15th March and following numbers ought to be received by the Member; should he by chance not receive it, there is some remedy, and I shall be obliged by his communicating with the Members who have not paid, and consequently have not received the March and following numbers will gladly understand that their subscriptions have not been received.

In conclusion I will only add that our relations are extended over the world, that our members live in 64 different countries, though the great divisions, the British Isles, United States, Australia, Canada, Germany and are only reckoned as one each. I claim that we are doing a large amount of seen and unseen good. We are a profit-making institution, though it is necessary to strengthen our backbone as we grow bigger. The JOURNAL is the flesh and muscles, the diffuser of the good work into it that energy is good seed—grow it will—we may not see how; but the world will be the better.

H. SCHWEITZER proposed a vote of thanks to the Treasurer for his continued and successful management of the financial affairs of the Society.

R. C. WOODCOCK seconded the motion, which was unanimously.

PRESIDENT'S ADDRESS.

THE MANAGEMENT OF A CHEMICAL INDUSTRIAL ORGANISATION.

I think it will be generally admitted, that the presidency of the Society of Chemical Industry is the highest honour kind within the reach of the chemical manufacturer, who pursue science in the abstract may hope for occasionally attain to niches in the Temple of Fame; no man whose life must be given up to its practical can hardly hope that such a result will crown his life. There may be other compensations, but fame cannot be expected. Not the least of these compensations is the opportunity that is afforded to so influence the work of others, that the world as well as the individual shall be the richer for it. Many a new discovery or useful invention would be still-born, if not at all, were it not for the aid, at the right time, of a practical man of science in affairs.

When you crossed the Atlantic and elected me to your Society, I held an exalted opinion of the office. I considered it as one of the highest honours which had come to my lot. Looking over the list of my distinguished predecessors, as I have often done, I beheld a long line of men who have had large influence for good in the world, of them having even attained to the niche in the Temple. Some have passed away, full of honours, to leave an account of useful lives; some remain for the work and the enjoyment of the fruits of that work accomplished. As I find myself about to be added to that list, I am humbled by the knowledge of the smallness of my services to the Society, and of my unworthiness to appear in that company. In one respect, however, I am the equal of any, and that is in the earnestness of my wish for the welfare of the Society, and that the Society shall profit in increasing measure by the work of its members. What the world already owes cannot be estimated. Its debt in the future will be limitless. The science of Chemistry and its applications enter very largely of life; and the men who form this and other societies, and those who shall be born into them, assume the major portion of the responsibility of the debt our science owes the world in turn.

This is an international Society, and yet it is after all a British Society. It was born here. Here it was nurtured wisely tended, during its childhood and youth, by members residing in all parts of the globe, it is, though not insular. Broad in its conception, its foundation, with a spirit of liberal conservatism, it has come from the beginning, and always will welcome, the science, theoretical or applied, of any country or language. What could be more natural, then, that its largest section should be in the new world, that the fourteen hundred or more members coming to it should be as loyal to the parent body, as the best living in the Old Country. If, however, anything needed to cement that loyalty, it was supplied when you elected, not only once but twice, an American President, thus giving additional evidence of that mutual respect and esteem which have been steadily growing among Anglo-Saxons everywhere, and which are to be potent forces working for the industrial welfare of the world, as well as for the peace of the nations.

The meeting in New York last year, the first ever held on this side of the Atlantic, was, I think, very successful, was largely due to the size and quality of the representation from this side, headed by that great scientist and one of good fellows, Sir William Ramsay. Ours is a country of magnificent distances, so we could do little in the three weeks allotted, than take you to St. Louis, give you a glimpse of the Exposition, and then, stopping occasionally to give the hospitality of one of our cities a chance to express itself. We were embarrassed by the number of invitations we were

obliged to decline, for your good. It was apparent on all sides that this Society was held in the highest esteem, and was widely known and understood. I allude to this memorable meeting, as I wish to thank you, on behalf of the American members, for coming over in such goodly numbers. You did us good. You brought us together closer than we had ever been brought before, and caused a cohesiveness in our membership, which on account of its rapid growth it needed greatly. I am glad that so many from our side are now returning the visit; and I thank you on their behalf as well as on my own, for the delightful programme you have prepared for our entertainment and instruction, in which everything is provided for except, possibly, time for meditation and sleep.

Residing as I do in New York, it has, of course, been impossible for me to attend the stated meetings of the Council, or to do many of the things which your President should do. Whatever may have been my own loss, the Society has not suffered, as my place has been more than filled by a resident Vice-President, Dr. Edward DRYDEN, soon to be your President-elect. I desire to thank him publicly, as I have already done in private, for this expression of his good will and loyalty. He will enter upon his duties as President *de facto* with a ripeness of experience, and a wealth of good wishes, which he will find to be very tangible assets indeed. I desire also to thank the Council for all the courtesies it has extended to me, and the kindnesses which have made me feel so comfortable in spite of my distance. I have been kept posted on all matters proposed. When delay would not be dangerous, my views have been awaited patiently, and, where advisable, have been carried out. In short, I have been made to feel that I was your President, without the fear that distance was preventing or hindering desired legislation. My correspondence with individual members also has been very delightful, and I realised I had made many friends, long before I had seen them, or felt the pressure of their hands. My experience since I landed on your shores has more than confirmed all that I have heard of English hospitality, and I have heard a great deal. I have, however, during my tenure of office, been able to perform at least one presidential duty of a most agreeable nature. I was present at and took part in the initial meeting of the New England Section, at Boston, on May 12th. I congratulate the Society on this latest acquisition, which I believe will develop into one of our largest sections, and trust its example will be followed in three or more other districts in the United States. The territory is much too large for one section, and many of the members have none of the advantages, except the JOURNAL. While this is worth the cost of membership many times over, it cannot take the place of regular meetings.

My distinguished predecessor, in his admirable address last year, gave the results of thirty years' experience in the education of chemists, as far as that education can be completed in the College laboratory. He suggested that I take up the question where he laid it down, and give the result of an experience, equal in years at least, from the point of view of one who made use of the chemist after graduation. He said: "The education of a chemist must be conceived in the sense that it consists in an effort to produce an attitude of mind rather than to instil definite knowledge. Of course, the latter must not be neglected." The "attitude of mind" is the pith of the matter. The young chemist, fresh from the College laboratory, is only after all just prepared to learn how to apply the knowledge he has acquired, and to build on it by his daily experiences. He must have learned how to study, and have a mind open to see the truth, and courage to follow wherever it may lead. He must have a good knowledge of the theory and science of Chemistry, and be expert in analytical work. If he has had a good teacher, he will have a strongly developed taste for research and original work, and considerable practice in the same; and to this end I recommend both teacher and student to commit Sir William's address to memory. It has occurred to me that it may be profitable to follow the suggestion though not too closely, even widening the field a little, and at the risk of dryness and over-abundance of detail, discuss the question of the

management of a chemical industrial organisation. In looking over the addresses of former presidents, I do not find this matter treated, and it seems to be a subject not out of place in a meeting of a society of the name and character of this. What I have to say will be but the expression of my own experience, and may vary widely from the views of others whose experiences have differed. Being the result of many years of observation and work of one who started as a raw chemical graduate, with but a single labourer to help him, it may be of some value to others, even if it serve only to emphasise what to avoid. In any event, I know the paper outlined has answered fairly well for the management of large and extended chemical industrial enterprises in a vast and rapidly growing country like the United States, and has stood the test of years in a company operating more than a score of plants, widely separated, and yet all working as a unit, controlled by the central governing body, but leaving the local managers sufficient freedom of action. While it possesses all the advantages of centralisation, it is intended to extract from the individuals of the staff wherever located, the entire benefit of their ability and superior knowledge of local conditions. I do not put it forward as novel, for I do not know whether it be novel or not; such matters not being often discussed publicly. In fact, I fear I may be addressing you on a subject with which many of you are more familiar than I am, even self; but I could hardly expect in this distinguished hearing to tell all of you something new and useful.

I have said that the plan is applicable in a large and rapidly growing country like the United States. I suppose it should be modified in a country in which industrial growth is slow. Few who have not lived in it, and studied the question carefully, can have an adequate idea of the wonderful progress made by the United States during the last thirty years, in the arts, manufactures and all else which makes for the greatness of a nation. And tower yet are those even of our own prophets, who have been bold enough to forecast the wonders of the future. The gradual though rapid unfolding of limitless resources which are only now beginning to be understood, remind one of an infant Newton attracted by the vision of his fingers and toes, and yet who knows nothing of the vast possibilities of his little life for time and eternity. Almost every natural resource needed by man in his most complex civilisation, is found there in prodigious abundance. Coal sufficient for ages. Water powers of wonderful proportions. Forests almost extensive enough to withstand the shortsighted and brutal assaults made on them by ignorance and greed. Ores of nearly all metals in surpassing abundance. Fields of grain and cotton, or tobacco and fruits sufficient to supply the home market and leave vast quantities for export. Such is the empire which in these last years has been opened up in some degree for its fortunate inhabitants, and for the benefit of that portion of the world less blessed with physical wealth. Whatever may be thought concerning the mission of the United States in the realms of thought and ethics, there can be no disagreement as to its destiny to supply food and raw materials to many millions without its borders. The growth of exports of manufactured goods as shown by statistical reports, indicates that we long ago entered the field as competitors for a share of the world's needs of these products as well.

In discussing the industrial future of the world we must take into account these new and enormous resources. The Americans did not create them. They might even feel humiliated that they have not accomplished more with them. The problems of the future for us are very great. If we were obliged to rely solely on natural increase of population, the unfolding would not be sufficiently rapid; but we are not. We can surely count upon a vast influx of immigrants, nearly a million a year, some of whom will be undesirable if it is true, but most of whom will make useful citizens after they have learned the difference between liberty and license, and have become assimilated and Americanised. Indeed, it is our pride that many come to us qualified from the start to bear their part of the burdens, and to contribute their full share to the elevation of the country.

Of course, in all this growth the chemical industry has

not stood still. It has kept full pace with all the changes. Thirty years ago it was comparatively insignificant. A study of the census reports for those three decades show startling advances. I shall leave the development of this subject to some future American President allude to it only as an excuse for the details to follow. In spite of its growth it is only in its youth, and to its full stature must be organised to accommodate it conditions which require almost constant construction of plants to meet the demand, and modifications to keep pace with the growth of knowledge.

I will pass over the necessary and customary Board of Directors, with its officers and Executive Committee, carry out its policies, simply saying that the success of any enterprise must depend very largely on the character and ability of its leading men. In the chemical industry they must of necessity include men educated as chemists and engineers, who are able to understand what subordinates are doing and to direct them as occasion offers. I have sometimes thought they must have virtues and graces, especially patience, as it sometimes takes many months to work out a process worth installing, and many years to bring to even partial completion important matters as the ammonia-soda process, the production of sulphuric acid by catalysis, and the coal tar chemical industry.

The detail work may be divided into the following general departments: Purchasing, Sales, Transportation, Finance, Construction, Operating, Research or Investigation, and Statistical; and yet all of these must closely interwoven and work in such harmony that best results shall be obtained without delay. To this object I have found it necessary to arrange committees composed as follows: First, a Manufacturing Committee; consisting of the managers of the Operating, Construction, Purchasing, and Investigation Departments, the chairman being the Chairman of the Executive Committee. This brings all departments having to do with the turning out of products, present and prospective, in regular and systematic touch with each other in the Executive Committee. Second, a Sales Committee, composed of the managers of the Sales, Operating, and Purchasing Departments, together with a member of the Executive Committee. This also results in a close touch of the department distributing products with the manufacturing department and with the active governing body.

The Purchasing Department should be managed by a man with a wide knowledge of the innumerable materials required in a large chemical enterprise, and where the best can be obtained. If he be also a good mechanical engineer so much the better, as that class of ability is frequently called upon in the purchase of parts of plants. If he be not, however, he must have the services of one at his disposal. In any case the efforts of the department must result in prompt work, properly inspected articles at low prices, and this is a most difficult and complex matter, as a large number of plants are calling constantly and simultaneously for supplies.

Time does not admit of a discussion of the work of the Sales, Transportation and Finance Department. To do them justice would be too great a tax on your patience. I have always believed that if your goods are wisely and economically produced—but not over-produced—the right geographical points, their sale follows almost as a matter of course. I do not pin my faith very strongly to that method of doing business, by means of which manufacturers by agreement fix prices without reference to cost, and thus court the competition which is sure to ensue. I believe that the best results in the long run are obtained by following natural laws wisely, rather than by combating them, invite the disaster is certain to follow the temporary benefit so derived.

The Operating Department is one of great complexity and importance, involving as it does all the details of the management of the various works in connection with the corps of superintendents and chemists and the foremen, processmen and labourers under them. Its headquarters should be in the main office of the company, in close touch with the officers. The questions daily before this department are so varied and of such great number that the necessity is a complete and systematic organization,

equipped as to be competent to carry on its business neatly and without confusion. Its affairs being so interwoven with the transactions of all of the other departments of the company, it is necessary that the complete co-operation should be maintained with all, whether located at the main office or at branch offices, and such methods must be employed as to prevent as possible the occurrence of friction in transactions where the interests of several departments are involved. The administration of this department should be conducted by a manager and assistant manager, who each morning for disposition of the mail, the discussion of such specific questions as require immediate attention, and for the formulation of general plans. The department being the one to which all technical questions are referred, except those concerning construction and litigation, its correspondence and telephone work is considerable, necessitating a suitable clerical force. From the questions submitted by correspondents, works in the vicinity of the head office receive daily instructions from the Operating Department regarding factoring, shipment of goods, &c. The manager and assistant manager, through membership on committees by frequent consultation with department heads, by correspondence with branch managers, are kept informed regarding the general policy and manufacturing of the company, and regulate manufacturing so far as possible in such manner as to provide a sufficiency of goods wherever required. While details of work management are of necessity left to the discretion of the various superintendents, this department should dictate general manufacturing policy to be pursued in accordance with the information which it collects by consultation with committees and with department heads relative to the company's manufacturing needs. Therefore the superintendents must look to this department for instructions defining the amount and quality of goods to be manufactured, and concerning all questions of works management requiring official direction and authorisation. The maintenance of the plants in a condition of proper manufacturing efficiency should receive continual attention, the cost of producing goods should be the subject of constant watchfulness. At frequent intervals the works should be visited by the manager or assistant manager for purposes of inspection and consultation with the superintendents. Upon these visits the physical condition of the plant should be carefully gone into, the methods of administration and manufacturing employed by the superintendents discussed, and such changes directed as appear warranted by the facts. Unusual trade demands strain points a deficiency of goods caused by interruption of manufacturing, the ability to produce goods cheaply in one works than another, owing to some change in conditions, and the greater convenience of one works as regards either or both the customer and the manufacturer, are all causes requiring the more or less frequent transfer of goods from one works to another. This department should watch the stocks on hand at the various works, and carefully regulate transfers in order to provide at points requiring additional amounts and to prevent the unnecessary moving of goods from one place to another. This is a more important question than it appears at first glance, and requires constant watchfulness. During periods of excessive trade demands it is an extremely difficult matter to so distribute the goods as to provide each works or shipping point with its proper share and to prevent a dearth of goods at any locality outside the jurisdiction of the department. It is, therefore, the policy of what precedes that the Order Department should be under the direction of the Operating Department. The Sales Department sells goods and designates the grade and where and when required, but the Operating Department alone can keep track of where the goods are located and can best decide regarding the proper grade to be peddled to each customer. Thus undue accumulations of stock at any point will be avoided, and advantage taken in the lowest freight rates in making deliveries. The costs of manufacture of every article produced by the company should be tabulated in detail each month in the Statistical Department, which will be alluded to later. From these records the Operating Department

is enabled to keep close watch upon the variation in the cost of producing goods and has constantly at hand a large amount of information to which frequent reference should be made in the conduct of manufacturing affairs.

This department naturally requires the services of a number of chemists used for the daily routine of the work. The selection of these men is highly important, as from their number may come those who will go into the research laboratory of the company, or possibly fill its superintendents' positions, and in later years its office. It is not sufficient that they shall show that they have received a good education and have completed a technical course, but they must evidence such personal characteristics as lead to the belief that they are capable of advancement to positions requiring the exercise of thought and judgment, and the assumption of responsibility. It is desirable that they should have some knowledge of mechanical engineering and the general principles of construction, but it has been found in my experience that this combination is rare, and we have been compelled in most cases to engage men who are either good chemists with but moderate knowledge of engineering, or good engineers possessing only an elementary knowledge of chemistry. It is to be hoped that the courses in technical chemistry now given in some of our colleges may turn out men better prepared for the work than those who have entered the field hitherto. In the past I have not found it a matter of so much importance from which technical school a man has obtained his degree, as that he should be practical, reliable, hard working and possessed of natural ability, and the capacity for development and advancement, or, as Sir William puts it, "have the right attitude of mind." As I have said before, the chemical education of the graduate can only be a foundation upon which the chemist who intends to become a manufacturer must build by study, observation and experience, and, therefore, it is only the ambitious, self-reliant, able, practical-minded men who can expect to graduate from the laboratory into the wider field of works management, where the personal equation is so largely a determining factor.

The apprentice should be kept long enough on one subject to make rapid and accurate analyses and at the same time be encouraged to make himself familiar with all the different methods of analysis bearing upon his particular work, and to be sure that he thoroughly understands the basic principles and theory upon which the work rests. For example, if a man be analysing sulphuric acid by the particular method employed by the company, he should not only know that method thoroughly, but by reading become familiar with all other methods of analysing sulphuric acid. Knowledge acquired in this way is apt to be more permanent than that acquired by promiscuous reading. After a sufficient experience along these lines, the apprentice arrives at a position where he may be able to improve existing methods or even invent new ones, owing largely to the thorough acquaintance with the needs of the department that would be apt to follow work and study carried on in this way. Of course all new methods he must test by rigid experiment before recommending.

In a works laboratory a variable degree of accuracy is required, depending upon the object for which the analysis is made. In some cases a tenth of 1 per cent. variation would not be serious. In other cases a ten-thousandth of 1 per cent., or even much less, is highly important, and as the object is to turn out analyses of the required accuracy in the least amount of time, it is of great advantage for the chemist to have such general knowledge of the use to be made of each analysis as will enable him to avoid waste of time in unnecessary accuracy. For routine work it is becoming more and more the custom to employ in works laboratories bright young men, graduates of high schools. Such young men are, of course, useful, but unless they pursue their scientific studies outside, as, for instance, at night schools, they are not likely to make great advances. In every laboratory there must be a chemist in control, who in turn shall be supervised by the chief chemist of the company. Unnecessary duplications being avoided, a force thus organised

becomes capable of doing an enormous amount of work in a given time and with great accuracy.

The apprentice confines his duties for a number of months, and frequently for years, to a works laboratory, and incidental to his analytical work he gains a certain knowledge of the general routine which obtains at that plant. After the laboratory service, if the chemist has displayed ability to advance, he is promoted to a position which will bring him into direct contact with the manufacturing processes, and his duties will gradually change from those of analyst to those of a manufacturing assistant, until he has become proficient enough to warrant promotion to the position of assistant superintendent, to which he is thereafter advanced at the earliest opportunity, either at the works at which he has received his tuition or at another works where such a position has become vacant.

The assistant superintendent is under the direction of the superintendent, and from him should receive a regular training in all the various duties pertaining to the position of superintendent, and when such a position becomes vacant, the assistant who, in the judgment of the department, is best qualified to fill the advanced position, is recommended for the promotion. The ability to administer chemical works can be obtained only by experience, and realising this fact the most efficient superintendents should act as teachers to the younger men in their development from one position to another.

Chemists who are not attracted by outside or works positions but who prefer research work, naturally graduate in due time from the works laboratory to the research laboratory. Occasionally one is found whose ambitions lie in the direction of mercantile affairs, for which he thinks the experience of the chemical laboratory will best qualify him. As a rule, however, the educated chemist does not select advancement in the Sales Department, or other business parts of the organisation, nor does it often happen that he is qualified.

The chemist, to succeed in technical work, must strive for material results. It has been my experience that the post-graduate course seems to incline him toward the search of learning rather than to its application. He must have a clear, logical mind, a singleness of purpose, and he must be able to separate the essential from the non-essential. This is true of all professions, but it is particularly true in chemical work, where the essential must be selected from an unusually large assortment of non-essentials.

The efficiency of a navy depends very largely on the "man behind the gun." So with chemists in a works or laboratory. The personal equation has much to do with the results. There is no "royal road" to success here. The rewards are for those who are willing to pay the price, and that price includes constant and intelligent work. The habit of study is rarely acquired after college days, and if the undergraduate does not develop it, he should seek a less exacting profession than that of chemistry, unless his ambitions will be satisfied with the daily grind of routine work.

The Construction Department, as its title implies, should have entire charge of the designing and construction of all new plants or parts of plants, and should, of course, act in the closest touch with the Investigation Department. In fact, all construction should be the result of careful investigation, and it rarely happens that it is wise to exactly duplicate a plant already constructed, for the reason that improvements are made so rapidly that a construction of a year or two in age frequently becomes in that time obsolete or partially so. This is one of the difficulties of all manufacturing business, but I believe the chemical industry from this cause is in a more difficult position than any other. The necessity of keeping plants up to the most modern standards makes an exceedingly large repair or reconstruction bill, which must not be lost sight of in determining the cost of the finished product. If this were more generally understood it would be better for the industry at large. No construction should be entered into that is not a part of a well digested plan, otherwise the result will be a heterogeneous mass of buildings and apparatus placed haphazard, without sufficient regard to the economical disposition of men, or the handling of materials. As a chemical industry,

like most others, is usually the growth of many years is, of course, difficult, but none the less important. Of course, no one is far-sighted enough to anticipate all requirements of the future, but I believe that if sufficient care be given to the question, enough can be foreseen to result in better engineering than we sometimes obtain in chemical plants.

The Construction Department should control all constructions, important repairs and maintenance. Maintenance requires the assistance of the Engineering Department. It is responsible for preparing specifications for all building materials, machinery, apparatus, and supplies required in connection with construction, important repairs, and approves of all works requis made in carrying out this branch of work.

Constructions include all new installations of apparatus, new structures, extensions or betterments of plants, and may be subdivided into constructions of plants and minor constructions.

1st. Constructions Proper.—These are formally authorized and numbered. Plans, specifications, and estimates are prepared, and presented to the Executive Committee for approval and appropriation before construction work is begun.

2nd. Minor Constructions.—These are authorized by the department without submission to the various committees for approval. They are aggregated quarterly and the necessary appropriation obtained for completion of the work. This list should be kept as short as possible and only permitted at all to save time in the many, but necessary matters which come up unexpectedly in chemical plants.

Superintendents should be encouraged to make recommendations to the Home Office for constructions which they deem necessary, but in no case should construction be permitted until the proper authority has been permitted by the Construction Department. A construction may be executed under the supervision of a works superintendent or by a special superintendent or inspector appointed at the discretion of the Construction Department.

Necessity for constructions may originate through recommendations of a superintendent, supported by the Operating Department, or may be ordered by the Executive Committee on account of general business developments. When a construction is settled upon, the Manager of the Construction Department confers with the General Manager, in order to arrive at a scheme of procedure which would be likely of adoption. The Engineer and Manager of the department then visit the works or property involved, to confer with the works Superintendent, if it be not found practicable to develop something by a study of the plans and records of the Superintendent in the head office. A pencil sketch with preliminary estimate is first prepared for a more intelligent consideration of the proposed construction and its cost. Consultations take place frequently with the Superintendent and Operating Department, so that no part may be omitted.

A construction at this stage does not reach the drafting office, and no attempt is made to develop plans until the approval of the General Manager has been received as to the form the proposal has now taken. When approval has been obtained, the design is put into the drafting office for development and final estimate. The final plans and estimates are presented to the Manufacturing Committee for approval, and recommendation made to the Executive Committee for the necessary appropriation.

When a plant is to be designed or built involving a new process or apparatus with which the staff is not familiar, the Investigation Department furnishes the data necessary or a consulting engineer is retained for that purpose.

The Investigation Department is that part of the manufacturing organisation which deals with all the propositions of a technical nature. Its work, which is entirely distinct from current manufacturing, has to do with new, and the improvement of old processes. A proposition is in the control of the Investigation Department from the time of its inception until sufficient data has been obtained to enable the Construction Department

sign the necessary plant, if one be authorised by Executive Committee. It is turned over to the Operating Department only after the process is working fully and the results considered satisfactory.

The organisation of the Investigation Department is sufficiently broad to permit the consideration of manufacturing proposition from the points of view of business man, the chemist, the engineer and the attorney. It consists of the Manager, a Chemical Engineer composed (in addition to the Manager) of the Chemical Engineer, the Chief Chemist who is or of the Research Laboratory, and such consulting chemists and engineers as the company employs. Appointments in this Council are intended to cover the most varied field of theoretical and technical chemistry, the Manager is permitted to consult outside experts if the company has not the necessary talent at hand. A group of chemists on Research Laboratory work, an expert of current chemical literature, patent experts, a small office force complete the department staff. The Research Laboratory, a body of chemists, under the supervision of the Chief Chemist, is employed on research work connected with investigation in hand. A limited number of men are permanently retained on research work.

The Research Laboratory reports weekly the progress of work in hand, and at the completion of each investigation sends in a statement of the steps taken, accompanied by the chief's recommendation as to further action. These reports are passed upon by the Chemical Council at its regular meetings.

Analyses required are made by the Analytical Laboratory, which is specially equipped for turning out quick and accurate estimations. Each works has its own analytical laboratory, but there is a central laboratory for the work of the head office. This laboratory itself examines and selects all analytical methods, which are adopted as standards and furnished to all laboratories.

The work of the Investigation Department originates from sources which may, in a general way, be divided into three classes:—

- (a) The probability of reducing manufacturing costs.
- (b) A decision to produce well established products not previously manufactured by the company.
- (c) New applications of science to industry.

The largest field is perhaps that of improving the processes at present in use at the different works, and which usually yields very profitable results. Aside from the chronic aim of the Operating Department to secure uniformly low costs, a decision to investigate a process in use may result from a drop in the market price of a product on account of trade conditions, or because the process is technically unsatisfactory. There may be developed, therefore, new methods or important modifications involving reconstruction or even new plants.

Consideration of the manufacture of products not previously produced by the company is usually given a high priority of market conditions or special wants of customers. A large consumption of a product of interest is developing, and the raw materials prove to be available. Investigation may be undertaken with a view to the introduction of a process and the construction of a plant.

The third source of investigation originates in the introduction of new processes so frequently offered to the company. Such processes, whether for a product manufactured by the company or of prospective interest, always given the attention which their merits seem to warrant. No one who has a sensible process to offer is refused a hearing, and the treatment accorded the process soon becomes public opinion. As a rule, the process is retained to direct the development of his work under the management of the department.

An investigation of a new manufacture includes a high examination of both the commercial and technical sides of the proposition, the commercial side, which the assistance of the Manager of the Sales

Department and other commercial branch is involved calls for consideration of the following:

1. Its relation to the interests of the company.
2. The market.
3. Manufacturing costs.
4. Investment necessary.
5. Source of raw materials.
6. Transportation.

1. *Its relation to the interests of the company.* The product should, in a general way, belong to its branch of chemistry. Consideration is frequently restricted by questions of policy, and the General Manager is always approachable if his views are required. The probable effects on the market of embarking in the manufacture must be studied. To a certain extent, new features arise in connection with the consideration of every proposition.

2. *The market.*—This calls for an examination of its general character and history, its probable stability, tonnage, whether local or general, and consequent freight costs; whether distributed over the twelve months or confined to a limited season, and the consequent question of storage and capital necessary to be tied up by goods in storage; cost of reaching the market, and advertising.

3. *Manufacturing Costs.*—This must have such a relation to the market price and the cost of marketing that a legitimate profit from the manufacture and sale of the product is apparent. No manufacturing should be undertaken for the purpose of injuring a competitor.

4. *Investment necessary.*—The investment must be so limited that a legitimate return is possible.

5. *Source of Raw Materials.*—The permanent availability of raw materials is a matter of the first consideration. As there is no likelihood of a chemical business controlling the supply of raw materials, the cost must at least be as low as that of any competitor.

6. *Transportation.*—Includes the investment and maintenance for containers, whether casks, drums, carboys, tank cars, tank boats or pipe lines.

On the technical side a study must be made of:—

1. The process.
2. Other processes.
3. Raw materials.
4. Quality of product required.

These topics indicate the method of working out or testing the practicability of the process. This phase of the proposition is entirely a chemical and engineering one, and calls for most of the work of the investigation staff.

In the usual order of procedure, a proposal reaching the Investigation Department is subjected to a preliminary consideration, and is entered for record if it is to be made a subject for investigation. It is then submitted to the Chemical Council, who decide on the method of investigation to be pursued. A résumé of the literature is generally made and a report obtained from foreign representatives on the latest European developments. We may soon have to add the Japanese. As the inquiry progresses, the Chemical Council, which meets weekly, is kept informed of the progress made.

The thorough consideration given at this early stage frequently prevents useless laboratory expense and much loss of time.

Where an investigation of a process in use is being made, a member of the Investigation Department is sent to each of the Works using it, to study the methods and management and analyse its defects. His reports thereon are considered by the Chemical Council in the manner indicated above.

If the final result of the investigation of a new process be favourable, an experimental plant may be recommended and an appropriation asked for. This may be advisable not only to assist in reaching a decision regarding the wisdom of adopting the process, but also for furnishing

data for the designing of a manufacturing plant, if one be ultimately decided upon.

In the case of the adoption of a process and the designing of a plant, the work of the Investigation and Construction Departments is very intimately connected. An investigation covers the inquiry regarding the proper design of the apparatus or plant, as well as the process *per se*.

Investigations in connection with construction naturally differ, to a certain extent, and include consideration of methods for handling the raw material, the solids, liquids and gases involved in the process; furnace, dissolving, filtering, evaporating, crystallising, distilling, subliming, drying, &c., and the packing and handling of the finished product.

The materials to be used in different parts of the construction are determined in an investigation into that important side be necessary, whether wood, cast iron, steel, lead, tin, aluminium, alloy, earthenware, porcelain, rubber, cement, &c. Any special data requested by the Construction Department in carrying out its work is furnished by the Investigation Department, such as the selection of fuel for special work, boiler and engine tests, consumption of steam, &c., and all chemical work.

The benefits resulting from organisation in the consideration of improvements and new processes are very evident. The results of experiments in one instance are applicable to others of distinctly different character. The full use of them demands a central bureau and clearing house of information.

The conferences held so frequently are not permitted to drag. Records are kept of all decisions, and even the local heads of departments present are notified in writing.

The routine work of the department consists in the collection and filing for easy access of technical and commercial data of all kinds connected with chemical manufacturing, for immediate and prospective use. Circulars containing useful information applicable to the works, and copies of research reports that may help operations, are transmitted to Superintendents. Records of failure are just as important as those of success. Every encouragement is given Superintendents to confer freely on any modifications, developments or conceptions which may occur to them. The *esprit de corps* resulting naturally reaches the junior men and foremen, so that a keen sense of responsibility and importance is felt throughout.

The frequent visits of Managers and Superintendents to the head office, and the periodic meetings of Superintendents which are called for conference and discussion enable the responsible men to continue in perfect familiarity with the technical resources of the company.

The Research Department would not be complete without a laboratory plant, large enough to work out processes on a small manufacturing scale. Such a plant should have all the standard appliances, and be so arranged that the results obtained in it are sufficient to form the basis for the engineering work resulting in the experimental plant to follow the successful investigation.

After all of the organisation has been perfected and the machinery lubricated and put in motion, it would be apt to run wild if some reliable and absolute method of control should not be at hand. This I have found completely accomplished by a department which has to do with the compilation of facts and the deductions from them. It is absolutely essential, in a company operating a number of plants, that those in control should not only know what each one of its manufactured products costs, but what enters into making up that cost, so that if for any reason there is a drain going on it will be quickly known, located and stopped; or if, on the other hand, something advantageous shall have been accomplished, that will also be noted and imitated at other points. This may seem like an exceedingly difficult undertaking in an industry of such infinite variety, but a brief consideration will show that it is not so. The Statistical Department, to which I allude, is not only able to advise the officers within a reasonable time after the end of each month of the cost of every product and step, but also of the profit or loss on each article and the total profit or loss of the company. These results have been so exact that for several years the profits

determined by public accountants at the end of the year have not varied 1 per cent. from those which have been worked up in this Statistical Department month by month. The importance of this information to those in control will be readily understood. For my own part, I see how it would be possible to intelligently run an enterprise involving a number of plants without such arrangement.

The exact plan which I would recommend is as follows:

Each factory furnishes monthly the following reports:

- Raw materials received.
- Raw materials used.
- Shipments of finished products.
- Stocks of raw materials.
- Stocks of finished products.

Productions and statement of statistical data (including manufacturing labour, labour on material taken from the storehouse for repairs, all material taken from the storehouse for manufacturing fuel and raw materials), packages, dry barrel included in the selling price and not returnable, factoring cartage (i.e., teams used around the steam and water.

The first shows the number of pounds of raw material received, together with cost of placing in the pile by adding the amount of bills, freight, &c., we get actual cost per hundred pounds of each. These are used in obtaining the material cost of each hundred pounds of production, which, with sundries, fuel and repairs, makes up the total manufacturing cost in connection with that shows what each department has accomplished during the month.

As each of the factory sheets is checked and every pound of raw material and finished product accounted for, nothing escapes which should be considered in cost.

In addition to the manufacturing cost are shown cost per 100 lbs. of special factory charges (including accounts as docks, dredging, fire equipment, labour, lighting, roads, maintenance of yards, watchmen, &c.) and cost per 100 lbs. of goods produced to salaries of superintendents and chemists, based on a proportion of labour of each department and the total manufacturing labour.

The factory shipment sheets are checked by the Accounting Department as well as repairs and net prices obtained, lighterage, cartage, allowances, cartage, freights, &c., being deducted.

By using the manufacturing costs and the net prices, we arrive each month at the gross manufacturing profits, and deducting taxes, insurance, office and other general expenses, the net results are obtained.

All organisation, whether in the chemical industry or any other, would fail to attain the best and most permanent results, if the personal equation be forgotten. We are not dealing with a collection of apparatus, but with an organisation of men, everyone an individual with his own peculiarities and ambitions. The best cannot come, if it ever will, when from purely altruistic motives a man will give his most efficient service. He must realise that while his best work must be done, it will not go unnoticed and unrewarded. He must be sure that he will receive just and proportionately liberal treatment. His proper ambitions must not be smothered, they must be directed. From an experience of many years, I believe the plan outlined above, provides fully the most important fact, and I can point with the greatest pleasure to many men as proof of my statement, every one more enthusiastic than at the beginning. The places of the leaders will some day be vacant. Who then shall fill them? Those whose lives have been spent in preparation for the work, and who will enter without shock or derangement of existing conditions, but as naturally as the stream flows into the river, will the natural ambition of the young man receive fulfilment in due time and thus will our beloved industry progress to points of attainment which some of us dream of, but will never see.

Dr. DIVERS, F.R.S., proposed a hearty vote of thanks to the President for his address, saying that he could not

no any subject of more interest and importance a Society of Chemical Industry, or to chemical facturing at large than that of the management chemical industrial organisation, especially when treated, as it had been, by a man of such great enee as their President. The benefit conferred the Society was inestimable. No words could be long for him to use in expressing on behalf of the y. of chemical technology, and of technical educa- tion, their high appreciation of this address. The storge happily made last year by their previous lent, Sir William Ramsay, that his successor, Dr. ls, should take up the subject of technical education he had dropped it, namely, at the point where uents had been trained at a College, University, or eal School, had been most happily adopted by resident.

S HENRY ROSCOE, F.R.S., said it was his great pleasure and the motion. He was almost overcome with the ordinary value of this discourse. To put it very y, it was a lesson to them from America—a wonder- ssion, a most valuable lesson; and it was for al manufacturers and all those interested in that industry to take this lesson to heart, if they could ary out all the splendid ideas of this wonderful sation which had been sketched out (and he doubted er it would be possible to find in this country an sation so complete as that which had been figured e President). Still, they could, no doubt, improve methods and adopt some, if not all, of the recom- tations which had been put before them, and so get enedit of this lesson from America. The idea unding the Society came from three of his s, whom he was proud and happy to see present that dr. Edmund Muspratt, Mr. Eustace Carey and Dr. ig Mend. Those gentlemen with some other friends to see him in Manchester nearly a quarter of a century sking his co-operation in the foundation of a Society. h, as they then thought, should be limited to the st of the manufacturing districts, that of South shire. He at once agreed with the desirability of ing a Society of the kind to bring together in con- mon the interests of those engaged in scientific try and in carrying out those principles in chemical ry, but he said that if it was worth doing at all s worth making a national society; and so the y arose. It had now become far more than a national y, for it was an international one. The fact that ad had two Presidents from the United States was ent proof of that. They all welcomed Dr. Nichols. hanked him for the address, and they would en- ur to carry out to the best of their ability the lessons ght. He wished to express on his own part, and he ure he was only the spokesman of all the British ers, the feeling that as time passed the two countries become united in still more common bonds, and hey might be brothers in heart and in deed.

Edw. DIVERS put the motion to the meeting, was carried by acclamation.

PRESIDENT then read the report of the Scrutineers, stated that 179 votes were cast, of which 11 were d. The nominations of the Council for the President ice-Presidents had been confirmed, and the following een duly elected ordinary members of Council: T. Dunn, Mr. Arthur R. Ling, Mr. J. S. McArthur, Dr. K. E. Markel.

PRESIDENT, having read the names of the retiring Presidents and Members of Council, said it was impossible to ask all those gentlemen to speak, ough he should have liked to have done so; but when nsidered that Mr. Tyrer had been on the Council at since the beginning, and had rendered yeoman ce in so many ways to the Society, it would not be e to let that opportunity pass without calling upon bi for a few words.

THOMAS TYRER said that they had never had any- th; but a unanimous vote in the acceptance of the

Reports of Council, and only two had the had their by-laws amended, once in a direction which they now regretted, when the subscription was reduced to £30, to 25s, with a view to increasing the influx of the younger members; but still the success of the Society, and then had shown that that step was after all not an unwelcome one. The only other alterations had been one or two of very minor character to facilitate business. He mentioned this because Sir Henry Roscoe had referred to the Society having grown to be international. The reason was that under his wise guidance and that of the Council at the time when they had no home or habitation, and no Council Meetings, the first Hon. General Secretary, Mr. George E. Davis, and Mr. Eustace Carey and himself (the Secretaries respectively for the North and the South), had a great deal to do in framing rules, which had never been altered, and which were framed on the basis referred to by Sir Henry, namely, that the Society should be so broad as to include everybody. They had had some difficulties and troubles, but through them all the Rules had been adhered to, and faithfully carried out; and the fact that they had been found equal to every stress and to the needs of every occasion, proved that the Society had been thoroughly well laid, and its foundation secured. He had had some experience in public, municipal and philanthropic matters and various governing bodies, but he had never heard greater freedom of expression and never seen so little friction, as in their Society. He felt it a great compliment to have been thus referred to, and he was very well satisfied in retiring to see how thoroughly the idea of internationalism was being carried out.

The PRESIDENT said it now became his very pleasing duty to inform the new President, Dr. Divers, of his election. Dr. Divers had, in fact, been the President of the Society for the past year, and he had done the work willingly, gladly, and very ably. He had intended to say something more on that point, but, as time pressed, he would reserve that for some other occasion, because he had something a little out of the ordinary to bring forward, and about which he hoped the Council would take appropriate action. That the Society at its formation had amongst its members 20 or 30 Americans was typical of the fact that, at any rate, from the standpoint of those gentlemen, it was an international society, and that American membership had grown until, in the New York and New England Sections, they had about 1500 members. He wished to state in the strongest possible terms that those 1500 gentlemen were members of the Society of Chemical Industry of Great Britain, and hoped to remain so, as long as the Lord would permit them. It was the desire of those gentlemen that there should be some little memento left with the English members of this visit. They did not quite know what to do, especially as they were aware that England was a country full of precedents, and they were afraid of destroying one at every turn. He did not know that he was not going to do something unprecedented now, but at any rate, he would take the blame. He found that the President of the Chemical Industry had no insignia of office in which to appear on public occasions such as the present. So they had ventured to provide something in the shape of a little medal which they hoped the Council would receive in the spirit in which it was offered, and instruct Dr. Divers and all future Presidents to wear it on official occasions.

The President then opened the case and displayed a very elegant star, having in the centre an excellent head of Sir Humphrey Davy, surrounded by the name of that Society, and an appropriate wreath joined together beneath by the two Hemispheres, the Eastern and the Western.

He hoped that as long as that Insignia of Office should endure, all Sections, whether in the New World or the Old World, would be part and parcel of the one old Society of Chemical Industry, started by the two or three men whom they had heard of that day. On behalf of the New York Section, he begged to present Dr. Divers with this medal, and to express the hope that the Council would instruct him to wear it on such occasions as might seem fit, and to hand it down to his successor as long as time should endure.

Dr. DIVERS said he desired to express his very deep appreciation of the honour which had been conferred upon him in electing him as President. He felt that the duties, with which he was somewhat familiar, were of an arduous character, and that the work of the Society at present was a very great work, that the possibilities of the future were exceedingly great, and that it required all the energies year by year of the President, supported by the other officers, to take full advantage of the opportunities that were presenting themselves. He therefore felt very deeply responsible of the task before him, but he would, as far as possible, emulate the example of his distinguished predecessors in office. With regard to the beautiful badge which had been brought over by the President, from himself and the American members, he could only thank him on behalf of the Society in general, and especially the British members, and could assure them that it would be greatly valued and esteemed as a special mark of the *rapprochement* that had been made between the members of the Society on both sides of the Atlantic.

On the motion of Mr. H. A. METZ, seconded by Mr. V. G. BLOEDE, Messrs. Miall, Wilkins, Randail, and Co. were appointed Auditors for the ensuing year, at a fee of 10 guineas.

Dr. G. H. BAILEY said that he had been requested by the Manchester Section to invite the Society to meet next year in Manchester. The Section would do everything possible to ensure the comfort, enjoyment, and instruction of the Society.

Mr. JULIUS HUBNER (Secretary of the Manchester Section) seconded the motion, and assured the Society of a hearty welcome.

Sir HENRY ROSCOE, as an old Manchester man, supported the resolution, which was carried unanimously.

Prof. C. F. CHANDLER, in moving a vote of thanks to the Council and Senate of University College, London, for the use of their room, said it was eminently appropriate that the Society of Chemical Industry should hold this meeting in London, in the first institution of the world that offered instruction in Practical Chemistry—an Institution which had been made familiar to every chemist in the civilised world by the eminent services rendered to chemical science by Sir Thomas Graham, Professor Williamson, and Sir Wm. Ramsay.

Sir BOVERTON REDWOOD seconded the motion, which was carried unanimously.

Sir WILLIAM RAMSAY, F.R.S., said the Council and Senate of University College had with the utmost willingness acceded to the request of the Council to place that room at their disposal. It had been the custom of the University College for the last 75 years to do all they could for the promotion of learning. Professor Chandler had mentioned the names of his predecessors in the Chair of Chemistry, but he ought to say that it was Professor Turner who, about 1828, opened his laboratories to a few young gentlemen. He was succeeded by Professor Graham, who subsequently became Master of the Mint, and by his colleague Professor Williamson, and he himself had the honour to succeed Professor Williamson. The College, therefore, had done its share in contributing what was possible to the advancement of chemistry.

The official business being then completed, the members adjourned to the Midland Hotel, where luncheon was provided by the London Section.

New York Section.

Meeting held at the Chemists' Club, on Friday, May 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

THE QUANTITATIVE ANALYSIS OF LARD

BY DAVID WESSON AND NATHANIEL J. LANE

It is proposed in this paper to collate and present in a compendious form the processes necessary to a complete quantitative analysis of lard. The methods here described have been employed by the writers in the course of somewhat wide and varied experience with satisfactory results. In many instances, the accuracy of the conclusions reached has been checked by work on samples the composition of which was known to the persons submitting the same, but not to the chemists.

In the preparation of commercial lard, the materials used are lard, cottonseed oil, oleostearin and paraffin. In lard compound the lard is omitted. Oleostearin paraffin has been detected, but this is a rare adulterant and only used by unscrupulous makers.

In the analysis the following preliminary qualitative tests should be made as follows:—1. The H test. 2. The Bechi test. 3. Microscopic examination. After which the following determinations are made:—(1.) Free acid as oleic. (2.) Titer test. (3.) Saponification value. (4.) Iodine value (Hübl or Wijs', not Iodine). (5.) Liquid acids and their iodine value. (6.) Warming and cooling test.

QUALITATIVE TESTS.

1. *Halphen test*.—This well-known test is applicable. It will not indicate cotton oil which has been heated to 150° C. in iron vessels. (Oilar, Amer. J., 24, 3.) It also fails to give a decided reaction with oils which have undergone special refining processes. This test is of value as a confirmation of other tests, or an indication, but must not be considered conclusive. (Lewkowitsch, Vol. II., page 534.)

2. *Bechi test*.—(Wesson's modification, J. Amer. Soc., 17, 725.) This method, while it has been superseded by the Halphen test, is nevertheless valuable on account of its speed. The solution required is made from alcohol, 160 c.c.; ether, 40 c.c.; silver nitrate, 1 g. Allow this to stand in the light until the supernatant liquid is clear; then decant into a glass stoppered bottle. Take about 50 c.c. of the melted lard, add an equal volume of 4 to 5 per cent. solution of sodium hydroxide, shake well and allow to stand on the water bath until it separates into two layers. Draw off the aqueous solution, and wash the residue twice with hot water; add the same volume of 2 per cent. nitric acid, warm, shake, settle and wash in the same manner. After the last washing has been drawn off, heat on the bath until the lard is clear, filtering if necessary. Take 10 c.c. of the lard and 10 c.c. of the solution in a small beaker, and heat on the water bath for fifteen minutes out of contact with the light. A reduction indicates the presence of cotton oil.

Without this purification there is usually enough reduction to render the result doubtful, although on occasions it may give none.

3. *Microscopic Examination*.—Melt 2 or 3 c.c. of lard in a test tube; dissolve in 7 or 8 c.c. of ether; the tube with cotton and allow to stand in a moderate cool place until crystals separate; decant the ether; melt the residue; re-dissolve it in ether, and crystallize again. Under a microscope with a power of 250 diameters the lard will show straight crystals with oblique ends, tall or oleostearin curved crystals with sharp pointed ends.

QUANTITATIVE TESTS.

Free Fatty Acids (Wesson's Method). Apparatus required.—A burette accurately divided into tenths; a convenient form is one holding 10 c.c., and about $\frac{1}{2}$ in. in diameter. A pipette deliver 7.05 grms. cottonseed oil at 15° C. A number of sample oil bottles. About 100 c.c. of phenolphthalein, 1 gm. dissolved in 100 c.c. alcohol. A solution of brine containing 150 grms. of sodium chloride per A one-fourth normal sodium hydroxide solution, using the salt solution add a few drops of the phthalein and run in enough of the caustic soda to render it slightly pink.

4 oz. bottle one half full of the salt solution, add 4 oz. of phenolphthalein, then fill pipette to the mark with the oil to be tested and deliver same into the bottle, draining the pipette carefully. Do not blow oil into the pipette. Start with the burette filled to the zero mark with the standard soda solution. Close the mouth of the bottle containing brine and oil and shake well, then add a few drops from the burette, shake thoroughly, continue until the salt solution has a distinct pink colour after continual shaking. Reading of the burette gives the percentage of free acid present.

Separation of the oily emulsion from the salt brine is observed the colour is hastened by holding the bottle in a slanting position.

Solids and solid fats the samples should be melted in salt solution heated 10° or 15° above their melting point.

Water Test.—By proposed method in U.S. Department of Agriculture, Circular No. 22:—

75 grms. of fat into a metal dish and saponify with 60 c.c. of 30 per cent. sodium hydrate (36 per cent. caustic soda) and 75 c.c. of 95 per cent. by volume alcohol, or 120 c.c. of water. Boil down to dryness, with stirring to prevent scorching. This should be done over a very low flame, or over an iron or asbestos plate.

Dissolve the dry soap in a litre of boiling water. Alcohol has been used, boil for 40 minutes in order to drive off the water, adding sufficient water to replace that lost. Add 100 c.c. of 30 per cent. sulphuric acid (unmixed sulphuric acid) to free the fatty acids, and boil to form a clear transparent layer. Collect the acids in a small beaker and place on the steam bath. The water has settled, then decant them into a dry filter, using a hot-water funnel, and dry twenty minutes at 100° C. When dried, cool the fatty acids to 20° C. above the expected titer and transfer to a test tube, which is 25 mm. in diameter and 100 mm. high (1 by 4 in.) and made of glass about 1 mm. in thickness. This is placed in a 16 oz. salt-mouth bottle of glass, about 70 mm. in diameter and 150 mm. high (6 in.), fitted with a cork, which is perforated so that the tube rigidly when in position. The thermometer graduated to 0.1° C., is suspended so that it can be stirred, and the mass is stirred slowly until the thermometer remains stationary for 30 seconds. The thermometer is then allowed to hang quietly, with the bulb in the centre of the mass, and the rise of the mercury noted. The highest point to which it rises is taken as the titer of the fatty acids.

The fatty acids are tested for complete saponification as follows:—

The c.c. of the fatty acids are placed in a test tube of c.c. of alcohol (95 per cent. by vol.) added. The mixture is brought to a boil and an equal volume of ammonia (0.96 sp. gr.) added. A clear solution should be turbidity indicating unsaponified fat. The room temperature must be reported.

Saponification Value.—This is taken as usual. It should be 193 to 198; a lower number would indicate the presence of paraffin.

Iodine Value.—The Hübl or Wijs' method should be used. The Hanus method is unsuitable owing to its peculiar action on the liquid acids of cottonseed oil, which will be referred to later. The iodine value of the lard is taken as a check; it has no significance in determining the composition of lard.

5. Liquid Acids and their Iodine Value. The method is based on the separation of the lead soap by ethyl ether or petroleum ether and is too well known to require a detailed description, which may be found in Leuckowitsch, Vol. I, p. 318, and J. Amer. Chem. Soc., Vol. 1893. There are several precautions which it is essential to observe. In saponifying the fat use pure ethyl alcohol, best prepared as follows: To ordinary alcohol add potassium permanganate in very fine powder or saturated solution until the pink colour holds for about 10 minutes; allow to stand overnight, filter and distil over a fixed oil and sodium hydroxide, the first portion of the distillate (about a quarter) being rejected. A sample of cotton oil having a liquid acid iodine value of 141.7 gave with impure alcohol a result of 131.7. The fat should be saponified as recommended by Muter in the original paper, by adding 50 c.c. of alcohol and about 1 gm. of pure potassium hydroxide to the fat in a 1 oz. Erlenmeyer flask, a guard tube being attached when boiling. It has been recommended to saponify with N/2 potassium hydroxide (stock solution); when a few days old this has a tendency to oxidise the unsaturated acids, as may be observed in the following results obtained with cotton oil by using an N/2 solution four days old.

	Regular Method.	N/2 Alkali.
Liquid acids	Per Cent. 76.29	Per Cent. 77.58
Iodine Value, Hübl	149.5	157.5
Iodine Value, Wijs	143.7	158.7

As low a result as 121 has been obtained by using an old N/2 solution. Furthermore, the ether solution of the liquid acids will be yellow instead of practically colourless as it should be. In precipitating the lead soaps use 1 gm. of lead acetate to each gm. of fat. Boiling the aqueous solution for five minutes after precipitation causes the lead soaps to fall down quicker, and the solution clears more readily on cooling. After the lead soaps are precipitated and washed, immerse the flask in a water-bath until the contents melt, then cool and shake out the water; it is unnecessary to dry. Dissolve the soaps in ether which has been distilled over calcium chloride; ether containing alcohol gives the amount of liquid acid too high, and their iodine values too low.

A lard gave these results:—

	Ether containing Alcohol.	Purified Ether.
Liquid acids	Per Cent. 68.00	Per Cent. 65.55
Iodine Value, Hübl	92.18	92.70

The use of the Buechner filter is an improvement in the filtration of the lead soaps. A convenient size is 10 cm. with three 12.5 cm. filter papers pressed on the plate with a bottle, which is nearly the same diameter as the funnel; this forms a tray-shaped filter. Use low suction, not more than 2 in. of mercury. If the filtrate is cloudy, it will clear on warming to 15°. The turbidity is due to cooling.

Another method is to weight 6 grms. and pour the ether solution into a 500 c.c. graduated tube. Dilute to 500 c.c., allow 2 c.c. for volume of precipitate, allow to stand overnight, and draw off an aliquot part, filtering if necessary, then proceed as usual (dilution method). This is especially recommended for use with petroleum ether.

If petroleum ether is used in the separation, the filtered solution should be decomposed with 20 per cent. acetic acid; when hydrochloric acid is employed, a compound is formed insoluble in petroleum ether and not decomposed by the acid. The liquid acids may be determined volumetrically or gravimetrically. The former method is far more rapid and convenient, the latter takes longer; it is difficult to get constant weight and guard against oxidation even when done in an atmosphere of carbonic acid, and the results are not as concordant. Apparently

there is some loss, the acids from the gravimetric determination requiring less alkali than is used for the acids in the same volume of ether. In a sample of cotton oil, the acids in 50 c.c. of the ether solution in the volumetric determination required 16.83 c.c. N/10 sodium hydroxide, while the weighed acids from the same volume required 16.70. In lard, the differences are greater.

The iodine value of the liquid acids should be determined by the Wijs' or Hübl method. The Hanus method fails to give concordant results on cotton oil liquid acid, as indicated by the following results.

Liquid acids

Iodine Value, Hanus	2 hours 142.0	3 hours 148.5
Iodine Value, Hanus	1 hour 145.0	3 hr 15 m. 152.4
Iodine Value, Hanus	1 hour 140.7	2 hours 147.1
Iodine Value, Wijs	1 hour 145.1	2 hours 143.7

The following results were obtained by the different methods on a sample of lard.

Ether not purified, solution not cooled.

Method	Ordinary Filter	Buechner.	Dilution.
Liquid acids—	Per Cent.	Per Cent.	Per Cent.
Vol.	67.48	68.00	67.12
Grav. (wt.)	—	67.45	—
Iodine Value—			
Hübl	93.00	92.18	91.60
Wijs'	12 hrs. 95.28	2 h. 25 m. 95.22	95.18
	12 h. 30 m. 95.28	3 h. 12 m. 94.85	—
Hanus	93.00	2 h. 25 m. 91.08	92.75
	—	3 h. 12 m. 91.90	—

Ether purified, solution cooled to 15° C.

Method.	Ordinary Filter.	Buechner.	Dilution.
Liquid acids—	Per Cent.	Per Cent.	Per Cent.
Vol.	65.30	1st 64.30 2nd 64.30	66.70
Grav. (wt.)	62.60	61.00 Diff. wt. sep. dets	—
Iodine Value—			
Hübl	94.50	96.35	93.72
Wijs'	96.78	96.83	95.62
Hanus	95.15	99.30	95.30

Ether Purified, Solution not Cooled.

Method.	Ordinary Filter.	Buechner.	Dilution.
Liquid acids	65.55	—	—
Iodine value, Hübl	92.70	—	—

	Liquid Acids		Iodine Value, Hübl.	Iodine Value, Wijs'.	Iodine Value, Hanus.
	Vol.	Grav.			
Highest	68.00	67.45	96.35	96.83	99.30
Lowest	64.30	61.00	91.60	94.85	91.88
Average	66.13	63.98	93.16	95.61	94.18
Difference	3.70	5.55	4.66	1.98	7.42

These results indicate that the lower the percentage of liquid acids found, the higher is the iodine value.

It will be seen from the above, that the Buechner filter gives the most accurate results (this has been proved on peanut and other oils repeatedly), also that the Wijs' is by far the best method for the iodine value, and that the ether solution of the lead soap should be cooled to 15° C. before filtration, in order to obtain concordant results. The Wijs' solution should be allowed to act for two hours, the Hübl overnight; this applies only to liquid acids. The following formula gives the per cent. of cotton oil.

a = Iodine value of liquid acids found.

b = Iodine value of liquid acids of lard (96—100).

c = Iodine value of liquid acids of cotton oil.

j = Per cent. of liquid acids found.

k = Per cent. of liquid acids in cotton oil.

x = Per cent. of cotton oil.

$$a - b = \frac{j}{k}$$

Then $\frac{a - b}{c - b} = x$.

$$c - b = k$$

The results are from 3 to 5 per cent. low when either is used in the separation, with petroleum nearly correct. (See this J., 1901, 1083.)

6. *Wesson's Cooling Test. Determination of Stearin in Lard Mixtures.*—Melted lard may be considered as a solution of the solid fats which it contains in which are liquid at ordinary temperatures. It has frequently been noticed in working with mixtures that a mixture of oleostearin and cottonseed oil of definite titer would crystallise at a much higher temperature than a mixture of pure lard of the same titer has also been noticed that a mixture of lard oil and stearin would crystallise at a much lower temperature than a similar mixture of lard oil and oleostearin. This is because the hard portions of the beef fat which constitute the bulk of the oleostearin are less soluble in cotton oil and lard oils at low temperatures than are the portions of hog fat.

In order to obtain the approximate amount of stearin in a mixture, it is, therefore, only necessary to observe the manner of its crystallisation as compared with a known mixture. This test will show as high as 2 or 3 per cent. of oleostearin when mixed with pure lard.

The apparatus required is as follows:—A 600 c.c. beaker, a 2000 c.c. beaker, a thermometer, and 6 test tubes. A piece of wood 8 in. square, $\frac{1}{2}$ in. thick, provided with six or eight holes to fit the test tubes and a hole in the centre for the thermometer, to be laid on top of the 600 c.c. beaker, and a thin piece of board or a large hole to fit the 600 c.c. beaker to be laid on top of the 2000 c.c. one. The apparatus is then put together.

The percentage of cottonseed oil having been determined, the approximate amount of oleostearin is calculated by the following formula

$$a - b' = \frac{3700 - 37b}{100} = 13x$$

When 37 is the average titer of lard; 33° average titer of cotton oil; 50° average titer of oleostearin; a = titer of sample; b the percentage of cotton oil found; b' = 33°; x the percentage of oleostearin.

In a sample of lard the titer was 38°, the cotton oil found by the liquid acid method 40 per cent. Then $33 \times 40 = 132$, $38 - 132 = 24.8$, $37 \times 40 = 1480$, $1480 \div 100 = 22.2$, $24.8 - 22.2 = 2.6$; $2.6 \div 13 = 20$ per cent. Therefore, 20 per cent. is the approximate amount of oleostearin in the sample. Make standards containing the per cent. of cotton oil found, lard, and 5, 2.5 and the same per cent. of oleostearin above and below that indicated by the formula. These standards are the carefully dried samples are filtered, as any moisture or solid particles of dust, &c., seriously interfere with the results. The test tubes are half filled with the standards and standards, and placed on the steam bath in a beaker of hot water, so that all may be of the same temperature. Sufficient distilled water to nearly fill the inner beaker is boiled to expel the air, and cooled to about 15° C. according to the melting point of the lard. The thermometer is inserted so that the bulb is in the lower part of the water, the beaker is put in the larger one, the test tubes corked and put through the holes, keeping the standards about half an inch from the bottom of the beaker by means of rubber bands around them. The apparatus is allowed to cool, and when the oleostearin commences to separate in the sample, it is compared with the standard which matches most closely and which consequently contains the same amount.

The cooling test must be taken as a whole. When the first indications (crystallising out) are generally correct,

will sometimes "catch up" with a standard, in case that standard must be taken as the correct one. This method may also be used in determining iodine. In making the standards, only the highest lowest in oleostearin need be made, the others obtained by mixing these in different measured amounts. The method is accurate to about 2 per cent., difference in gravity would be negligible. Three cent. of oleostearin in lard may easily be detected and removed.

In many cases, the calculations on the titer give a very slight; nevertheless, this should not be taken, as a good test has been found by experience to be far more accurate.

Following results were obtained by the formula and test on lard:—

Composition of Lard.	1.	2.	3.
.....	70.0	70.0	30.0
.....	15.0	25.0	60.0
.....	15.0	5.0	10.0
..... indicated by cooling test			
..... indicated by calculation on			
.....	17.35	7.5	11.5
.....	38.8°	36.3°	36.1°

CONCLUSIONS.

At present time there is no method for the detection of tallow, its constants being very similar to those of lard. It can only be detected qualitatively by the phytosterol test. The phytosterol test is probably one of the best methods for detecting vegetable oil in lard, but is not mentioned in this paper, because it was not in use when the writers were doing the work described. The methods described will give results which are to about 3 per cent. of the truth, and sufficiently accurate for commercial purposes. While the lard having the high iodine value of 115 on the liquid acids test (Vol. II., p. 788) may occasionally occur, it is infrequent to be taken into consideration.

Nottingham Section.

Held at Nottingham on Wednesday, May 24th, 1905.

MR. J. T. WOOD IN THE CHAIR.

TEMPERATURE CORRECTIONS FOR USE WITH THE ABBE REFRACTOMETER, AND REFRACTIVE INDICES OF SOME FIXED AND ESSENTIAL OILS.

BY T. F. HARVEY.

The determination of the refractive index of fluid substances is now a somewhat common laboratory operation. For ordinary commercial work the Abbe refractometer when fitted with a constant temperature attachment is very convenient. The readings obtained with this instrument by a practised observer are easily reduced to 0.0002. It has distinct advantages over the Pyro-Refractometer in that (1) it possesses a wide range of temperature, (2) it enables one to determine the refractive index of most substances, (3) by means of a special arrangement a sharply defined shadow, free from fringes, can always be obtained, (4) the instrument can at any time be checked and adjusted if necessary against pure distilled water. With liquid substances the use of a thermostat may be entirely avoided, the operation much simplified by making the observa-

tion at the temperature of the water bath. In the case of the main, reducing the readings to 0.0002 at 20° C. is not difficult, as the temperature, viz., 20° C. To ensure that the water and oil are at a common temperature the water should be allowed to circulate for about half an hour before the oil is introduced. No attention being required during the observation, solid fats at an elevated temperature may be used. Very few temperature corrections have been published. A few scattered ones have been found, e.g., Allen (Commercial Organic Analysis, Vol. II, p. 14) quotes from the Bulletin of the A.O.A.C. the corrections for butter fat as 0.000176. This appears to be erroneous, since I find the value 0.00036 on three samples, which is in agreement with the Zeiss correction, published for use with the Butyro-Refractometer, and is also in keeping with my other figures.

Lewkowitsch gives the correction in the case of pure water as 0.00008 for 1° C. Tölg and Manson calculated the correction for oils from observations made by Procter as 0.000365. Listing gives the correction 0.00032 for glycerin of sp. gr. 1.2535. Table I. gives the corrections for each 1° C. expressed as units of the fourth decimal, e.g., the correction for olive oil is 0.00036. The corrections are negative for lower temperatures than the standard temperature adopted, and positive for higher temperatures than the standard, since the refractive index decreases with rise of temperature. Two series of observations were made in each case, the lower at about 16° C., the higher about 25° C., each series comprising several observations. To test the accuracy of these corrections the refractive indices of a few oils were determined in the usual manner, and also directly at 20° C., with the following results:—

	Rape Oil.	Bergamot Oil.	Cubeb Oil.	Sandalwood Oil.
n _d at 12.5° C. calculated to 20° C.	1.4728	1.4666	1.4976	1.5057
n _d observed at 20° C.	1.4729	1.4667	1.4977	1.5057

It may be noted that the temperature effect due to the glass of the prisms is so small as to be negligible over a range of 30° C. See Pulfrich in "Zeitschrift für Instrumentenkunde," 1898.

Appended is also a table of refractive indices of a number of fixed and essential oils obtained in the ordinary routine work of the laboratory, distilled water at 20° C. being taken as 1.3330. Care has been taken to exclude all oils of doubtful purity. In no case were free fatty acids removed from fixed oils by washing with alcohol as has been recommended by some observers, an erroneous procedure with this class of instrument.

Most of the observations recorded in this paper have been made by my assistant, Mr. A. Tompkin.

DISCUSSION.

Mr. WHITE said the Abbe Refractometer did not appear to him to be so useful as the Zeiss Butyro-Refractometer. The latter apparatus showed on an arbitrary scale the difference between butter and margarine, and was therefore of some value in applying a "sorting" test. The actual refractive index of the substance examined was not often wanted. The Butyro-Refractometer could also be used for the examination of other oils and fats.

Mr. S. R. TROTMAN thought the instrument had many advantages over the Butyro-Refractometer; at the same time he thought the refractive index of little use except in case of very gross adulteration, and he could hardly recall more than six examples where it had been of much use to him in detecting 10 or 20 per cent. of adulteration. In a cod oil, for instance, the difference caused by 90 per cent. of adulteration might be taken to be simply due to experimental error.

Mr. S. F. BLUFORD expressed himself satisfied with the earlier instrument of Jean. He asked also whether clarifying the oils by means of calcium chloride would not give more constant results.

Mr. T. F. HARVEY, in reply to questions, said the refractive indices of petroleum products used for acidifying turpentine would be liable to much variation that he thought one of the best ways of examining turpentine, and the one which he had adopted, fractionate 50 or 100 c.c. and take the refractive index of the fractions.

The refractometer was of great value in the case of series of oils coming from the same source, giving an indication of their uniformity, and so avoiding the necessity of making a complete analysis of each. Persons had found it a most useful instrument for examining medicinal cod liver oils—for fresh cod oils the refractive index was nearly proportional to the iodine value; in fact the latter could usually be calculated from it within one or two units. The refractive index was doubtfully of most use for fixed oils showing extreme values such as sperm, linseed and castor. For essential oils systematic fractional distillation, as in the case of turpentine, greatly enhanced its value.

The instrument was just as useful for butter. The Butyro-Refractometer. In point of delicacy the two instruments were nearly comparable, on the Abbe equalling about 0.0007 on the Zeiss Refractometer. The alteration in refractive index caused by temperature was practically constant for the same substance, and was very appreciable for butter no matter what instrument was used. He thought it a mistake to remove free fatty acids from butter by washing with alcohol previous to determining the refractive index. The oils were liable to oxidation and alteration during the process, with consequent changes of refractive index, and the beautiful rapidity of the method was destroyed.

Meeting held at Nottingham on Wednesday, May 24th, 1905.

MR. J. T. WOOD IN THE CHAIR.

THE COMPOSITION OF NUX VOMICA SEEDS.

BY T. F. HARVEY AND J. M. WILKIE.

The occurrence of fat in nux vomica seeds has long been a source of annoyance in pharmaceutical preparations. On exposure of the liquid extract of the seeds to the air, deposits of fat are so common that various devices have been suggested for eliminating them during the process of manufacture. Since a examination of the fat presented somewhat unusual features, it seemed desirable to examine it somewhat in detail.

The only references we have found concerning nux vomica fat have been the following:—

Bullock ("Year Book of Pharmacy," 1871, 290) obtained 5 pints of oil from 150 lb. of nux vomica seeds.

Greenish and Smith (*Pharmaceutical Journal*, Dec., 1901, 667) found in nux vomica seed from 2.6 to 7 per cent. of fat (average, 3.2).

Pancoast and Graham (*Analyst*, 1904, 121) give a value of 0.935 at 15° C.

Three samples of fat were prepared by percolating with ether from nux vomica seeds reduced to powder, after being removed from the ethereal solution by agitation with dilute acid, about 4 per cent. of the fat being obtained.

The fats so prepared varied somewhat in consistency; all were slightly fluorescent when melted, of a yellowish

colour, with characteristic odour, and an ant taste, but not bitter.

ecular nature of the fat appears at once from its tent of unsaponifiable matter and great variation oil, the latter ranging from 56.7 in (a) to 69 in (b) d as oleic.

isaponifiable matter amounts to 12.4 per cent. in 12 per cent. in (b), and probably exists in a free n, at any rate in sample (b).

a yellow, waxy, rather sticky substance bearing able resemblance to anhydrous wool-fat, and d of a harsh odour. It therefore does not appear ble the well-known aliphatic alcohols, while its also is much higher than that of phytosterol or ol. Yet, after partial purification with alcohol, e colour reactions were obtained somewhat ng those of cholesterol or phytosterol.

pts to crystallise it from absolute and slightly l alcohol were unsuccessful, as also from chloro- nyl acetate, ether, and petroleum ether. On tions evaporation of the alcoholic solutions an s substance progressively separated which after eatments with alcohol still refused to crystallise, xperiments were temporarily abandoned through material. No greater success has yet attended o to crystallise the acetates.

olid fatty acids were repeatedly crystallised from e the last melting point obtained being 69.5, g the presence of stearic acid.

iquid fatty acids seemed to possess no abnormal rs, the iodine value and mean molecular weight ating much from those of pure oleic acid.

lycerol in sample (b) was estimated in the usual y by oxidation with permanganate in alkaline are being taken to eliminate other substances ight give rise to the formation of oxalic acid. tion was also obtained by the actual isolation 9 per cent. of impure glycerol.

her characters of the fat, as shown by analysis, are e the appended table:—

	Sample (A)	Sample (B)	Sample (C)
Specific gravity, 100/15.5 C.	0.8638	—	—
Melting point	Softens at 29.4° C. Clear at 41.2° C.	—	—

Acetyl value, ditto	—	105.9	—
Specific rotation, ditto in chloroform sol.	—	+ 39	—

DISCUSSION.

MR. T. F. HARVEY, in reply to questions, said that they had not been able to account for the great variation in the content of free acid in the different samples. They had found it was not due to enzymic action occurring after the seeds had been ground, for the fat from different samples of freshly-ground seed still showed the same great variation. The unsaponifiable matter was strongly dextro-rotatory; no combustion experiments had been made upon it, since the authors had not yet obtained from it anything of the nature of a pure substance.

ts of Electric Incandescent Lamps; A New Form of Carbon Specially Suitable for —, H. C. Lewis, Jr. From General Electric Co. of Schenectady, N. Y. Eng. Pat. 6959 A., March 22, 1904.

ment is first formed in the usual way, and then to a high temperature in a carbon tube electric It is afterwards "flashed" in the presence of a rhon, and then again heated very strongly in ance. The resulting carbon filament consists of a m of graphite, the specific resistance of which at apertures is less, and at high temperatures is than that of the ordinary filament; it is very nd flexible, and is claimed to last much longer and ore efficient.—W. H. C.

UNITED STATES PATENTS.

Bagasse-Burning —, H. G. Gimera and J. Keech, Honolulu. U.S. Pat. 791,023, May 30,

nace consists of a front wall and a rear wall, a y short horizontal grate at the lower end of the ll, an inclined, step-ladder grate, which supports asse as it burns and extends from the horizontal ward towards the front wall, an inclined floor, ng from the top of the inclined grate to the front hich the bagasse rests before it reaches the grate, ction depending from the arch of the furnace the inclined floor and forming with the rear wall ution chamber above the inclined grate; lastly, ue in the rear wall at its lower end, for delivering above the horizontal grate, the rear wall extending to the same height as the downward projection ng a throat-way above it for the products of tion.—J. F. B.

Combustion; Process of Preparing —, G. W. d and T. A. Tyas, Hoboken, N.J. U.S. Pat. 9 13, June 6, 1905.

air are mixed and heated in a chamber, and the mixture formed together with the unvaporised hen passed downwards through a narrow passage, hey are agitated together, into a second chamber, econd chamber the mixture is further heated and d downwards to the burner.—W. H. C.

ducer Apparatus, C. Ellis, New York. U.S. Pat. 791,461, June 6, 1905.

RODUCER is combined with a gas-burning furnace extensive "baffling-surfaces" and containing one receptacles for the material to be heated. By a arrangement of flues and a fan or other draughting device, a regulated portion of the products ustion is returned to the producer mixed with a d quantity of air. The mixture is preheated in y the hot products of combustion.—W. H. C.

Apparatus for Washing —, J. S. Oursler, nor to J. Reis, Newcastle, Pa. U.S. Pat. 791,160, 30, 1905.

paratus consists of a receiving chamber having a t pipe, and placed above a washing chamber a gas-outlet pipe. In the bottom of the receiving r, a number of dust-receiving pockets are formed, s passes from the receiving to the washing vessel row channel, having vertical sides, and projecting rds to a point just below the level of the water n the washing chamber. The pockets, which have penings at the bottom, are separated by vertical ns, placed between them and reaching to a point ow the level of the water outlet.—W. H. C.

FRENCH PATENTS.

Mineral or Vegetable Origin; Process for Reducing Density of] —, in View of their Application as A. Cănera di Salasco and C. Rovere. Fr. Pat. 77, Dec. 7, 1904.

g. Pat. 26,192 of 1904; this J., 1905, 236.—T. F. B.

Briquettes; Process of Consolidating — by means of the Agglutinant, B. Wagner. Fr. Pat. 300,536, Jan. 5, 1905.

Two briquettes are passed continuously through a steadily inclined tube, through which furnace gases flow in the opposite direction. The tube is rotated so that the briquettes, as they travel forward, are turned over and over, exposing each side in turn to the action of the gases. The briquettes leave the tube at the lower end, through an opening provided with a flap door, opening outwards. This allows the briquettes to pass out easily, but hinders the entrance of air which might cause combustion of the material.—W. H. C.

Coke Ovens; Evacuate Coppers —, E. Coppée. Second Addition, dated Dec. 30, 1904, to Fr. Pat. 299,799, July 13, 1899.

According to the present additional patent, the conduit through which the mixture of gas and air is conveyed to the heating flues, is constructed with a progressively decreasing cross-section, the object being to ensure a more uniform distribution of the mixture, and also, owing to the increased velocity consequent upon the diminishing section, to prevent it burning in the conduit before reaching the heating flues.—W. H. C.

Gas; Process for Making a Combustible —, J. Bowing. Fr. Pat. 349,426, Dec. 22, 1904. Under Int. Conv., Dec. 28, 1903.

SEE Eng. Pat. 28,498 of 1903; this J., 1904, 1140.—T. F. B.

Gas Generator, A. von Kerpely. Fr. Pat. 350,509, Jan. 3, 1905.

SEE Eng. Pat. 28,966 of 1904; this J., 1905, 324.—T. F. B.

Gases; Electro-catalytic Process for Obtaining Fixed — from any Carburetted Body, A. A. Eveno. Fr. Pat. 350,528, Jan. 4, 1905.

This invention consists of a process of obtaining gases, such as hydrogen, oxides of carbon, methane, ethylene, &c., from a carburetted body for lighting or heating purposes, the feeding of motors, &c. The liquid is submitted in the form of spray to the action of the electric spark or an electric discharge at a high tension, in the presence of catalytic bodies such as platinum, iridium, &c.—B. N.

Gas; Process of Desulphurising Illuminating — by means of Ozone, J. Marchal. Fr. Pat. 350,679, Jan. 11, 1905.

SEE Eng. Pat. 28,765 of 1904; this J., 1905, 491.—T. F. B.

Gases from Explosion Motors; Utilisation of Nitrogen contained in Exhaust —, E. Bombard-Praciq. Fr. Pat. 349,425, Dec. 22, 1904.

THE claim is for the use of compressed exhaust gases from explosion motors, which after purification consist of nearly pure nitrogen, instead of compressed air to displace combustible liquids from monte-jus apparatus or blowing eggs. The absence of oxygen prevents any danger of explosion.—W. H. C.

GERMAN PATENTS.

Briquettes; Process for the Manufacture of Durable — by means of a Binding Agent Soluble in Water, Sächsisches Bankges. Quellmalz und Co. Ger. Pat. 158,497, June 14, 1901.

THE briquettes are exposed to a temperature at which the binding material is carbonised or coked, whilst the combustible material from which the briquette was prepared suffers no appreciable alteration.—A. S.

Briquette with an outer Layer consisting of a Mixture of an Oxygen-yielding and a Combustible Substance, F. Schumann and F. Sattler. Ger. Pat. 158,469, July 25, 1903.

A LARGE portion of the surface of the briquette is provided with a coating of a mixture of an oxygen-yielding sub-

stance and a combustible material (powdered charcoal, &c.) the composition of the mixture being so adjusted that the oxygen-content of this coating progressively decreases from the outside towards the interior, so that on placing the briquette in the fire, the first evolution of gas is accompanied by the strongest evolution of oxygen, whilst as the briquette burns away, the amount of oxygen evolved diminishes concurrently with the amount of gas produced.—A. S.

Fuel from Carbonised Peat: Process for the Manufacture of Artificial — J. Kuops. Ger. Pat. 158,756, Feb. 16, 1904.

THE binding agent used consists of a meal prepared by boiling leather waste and grinding the dried residue. Peat charcoal is mixed with this meal, and briquettes are formed from the mixture by the simultaneous application of heat and pressure.—A. S.

Water-gas: Process for the Purification of — W. Lazarus. Ger. Pat. 159,136, March 19, 1904.

THE water-gas is first passed through a heated retort filled with coke, whereby the carbon dioxide contained in it is converted into carbon monoxide, and is then freed from sulphur and cyanogen by passing it, in the hot condition, over oxides, hydroxides, carbonates or silicates of alkali, alkaline earth, or earth metals, or the oxides or hydroxides of iron or zinc, heated for example to 500° C.—A. S.

Gas Retorts: Process for Cleaning — by means of Compressed Air. Berlin-Anhaltische Maschinenbau Act.-Ges. Ger. Pat. 159,203, April 4, 1904. Addition to Ger. Pat. 149,854, Feb. 24, 1903.

AFTER the layer of tar and carbonaceous matter adhering to the walls of the retort has been burned by the aid of compressed air, steam, together with air under a lesser pressure is introduced, in order by reduction of pressure in the retorts to accelerate the removal of the graphite adhering to the walls. The steam may be introduced directly into the retorts, or may be produced in the retorts from water introduced through the air-inlet pipe.—A. S.

Mantles for Oxygen-Coal-gas Burners: Process for the Manufacture of Incandescence — S. Saubermann. Ger. Pat. 157,811, March 18, 1903.

A TEXTILE fabric is impregnated with a solution of calcium and cerium nitrates or of calcium-zirconium and cerium nitrates, then dried, ignited, immersed in a solution of thorium nitrate, either pure or containing cerium, and again ignited. It is stated that by this after-treatment with thorium nitrate, the illuminating power of the mantle is increased to a much greater extent than by impregnating with an equal quantity of thorium nitrate added to the first bath.—A. S.

Carbon Electrodes of Arc Lamps: Process for the Utilisation of Waste — R. Peters. Ger. Pat. 158,151, Jan. 19, 1904. XIII. 1., page 742.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

Pyridine: Purification of — [also Determination of Ammonia in Pyridine, and Preparation of Ammonium Magnesium Phosphate and its Substitution Derivatives]. L. Barthe. Bull. Soc. Chim., 1905, 33, 659–661.

COMMERCIAL samples of pyridine contain from 1 to 20 per cent. of ammonia, which cannot be completely removed by ordinary methods of separation. It is removed by the author by shaking with magnesium hydrogen phosphate, $MgHPO_4$, in excess, together with a very little water, filtering, and rectifying. Pyridine, freed in this manner

from ammonia, does not turn litmus solution distinctly blue, but only to an undecided claret colour. It is therefore possible to determine the amount of ammonia in commercial pyridine by titration with N/10 sulphuric acid, using litmus solution as an indicator. Ammonium magnesium phosphate and its aliphatic derivatives, such as methylammonium magnesium phosphate, $Mg(NH_2CH_3)PO_4$, may be prepared by agitating magnesium hydrogen phosphate with ammonia or an amine in presence of water.—E. F.

ENGLISH PATENT.

Spirituous Fluid from Water-Gas Tar and Process for Obtaining Same. W. Oppenheimer and T. C. London. Eng. Pat. 4271, Feb. 20, 1904.

WATER-GAS tar from which the greater part of the water has been removed (see Fr. Pat. 334,472 of 1903; 1904, 55) is distilled until the residue consists of a pitch; the distillate is then acidified, neutralised, distilled, the distillation being continued until the distillate assumes a yellow tinge and an oily nature, the process is then repeated. The product has then a density of 0.86–0.94, and contains toluene, the xylenes, and a trace of naphthalene. It is intended for use as a solvent for rubber, resins, &c., and also for purposes; it is stated to have a higher flash point than petroleum.—T. F. B.

UNITED STATES PATENTS.

Wood Distillation: Retort for — A. J. Assignor to the International Wood Distill Co., Cleveland. U.S. Pat. 790,097, May 16, 1905.

THE still consists of an inner retort adapted to receive charge of wood, surrounded by an outer casing, in a manner as to leave a space between the latter and the sides of the inner retort. The furnace, placed around the retort, is connected with the space between the retort and the casing by means of flues. Both the retort and the casing are divided into a series of compartments by vertical partitions; in each of these compartments is provided a valved outlet pipe connected with a main pipe. Air inlets are also provided in the lower parts of each compartment.—T. F. B.

Ammonia-Still. H. A. Abendroth, Berlin, Germany. U.S. Pat. 792,379, June 13, 1905.

THE still consists of a series of superimposed compartments, the bottoms of which are constructed to form inclined terraces, each of which has terraces sloping from the point of inflow to the point of outflow of the ammonia water. All of the terraces except the highest and lowest are provided with hooded steam-inlet pipes. (Compare U.S. Pat. 712,891 of 1902; and 771,031 of 1904; this J. 1902, 1526, and 1904, 978.)—E. S.

GERMAN PATENTS.

Hydrochloric Acid: Manufacture of — with the Simultaneous Recovery of the Products of the Distillation of Wood. Bosnische Elektrizitäts A.-Ges. Ger. Pat. 158,086, April 24, 1903.

IT is claimed that by subjecting wood or allied substances, such as cellulose, paper, peat, &c., to distillation at 150°–350° C., in a current of chlorine, 70 per cent. of the latter is converted into hydrochloric acid, while the distillation products of the wood, &c., contain much smaller quantities of substances of empyreumatic nature than those obtained in the usual manner. In carrying out the process, the retorts, which are provided with thermometers, are heated slowly to 150° C., and chlorine is then introduced. The reaction which takes place causes a rise of temperature, so that further heating of the retorts is unnecessary. When the temperature falls considerably, the supply of chlorine is cut off, and the retorts are heated strongly, in order to extract the chlorine from the residual charcoal.—A. S.

ignite and the like; Process of and Furnace for Coking Combustible Substances containing Large Quantities of Moisture, such as —. P. Hoeting and Mjöen. Ger. Pat. 158,032, June 27, 1903.

Steam evolved from the fresh charge of peat, &c., cooler part of the furnace is led away with the gaseous products, either directly or after being heated in the coking zone of the same or a neighbouring furnace. The cooler part of the furnace through which the peat, &c., passes first, communicates by a suitable connection (hopper, or the like) with the coking zone of the furnace, or an adjacent furnace; the gas-discharge pipes from the coking zone of the furnace. By this means the dry peat which is being carbonised in the coking zone is subjected to the action of the steam evolved during the drying of the wet peat, whereby, it is dried, larger yields of tar and ammonia are obtained. A. S.

Carbons, especially Mineral Oils; Process and Apparatus for Drying —. Dampfkessel- und Gasmaschinen-Fabrik vorm. A. Wilke and Co. Ger. Pat. 158,032, July 14, 1903.

hydrocarbon or mineral oil is heated by hot air (which is forced through *b*) to 100° C., in the apparatus shown in the figure; the steam and light oils are condensed in the denser *e*, and run back through the pipes *f* to the bottom of the vessel, where they are no longer heated, but run off from time to time by the cock *g*.—T. F. B.

IV.—COLOURING MATTERS AND DYESTUFFS.

Compounds [and Nitrites]; Reduction of — with Sodium Hydrosulphite. J. Aloy and Rabaut. Bull. Chim., 1905, 33, 654—655.

The authors reduced various nitro compounds of both aromatic and the fatty series by boiling with con-

centrated sodium hydrosulphite solution. The reduction of aniline and *n*-naphthylamine from the nitro compounds were good. The yield from nitro compounds such as *m*-dinitrobenzene was poor. 1,2- and 1,4-nitrophenols were reduced to the corresponding aminephenols. Nitroethane was reduced to ethylamine, at least, to methylamine. Nitroacetone was easily reduced by sodium hydrosulphite to the corresponding acetone; nitrites, on the contrary, were not reduced. E. F.

Diazo-Derivatives of Monosubstituted Aromatic Para-diamines. G. T. Morgan and F. M. G. McIlhenny. Chem. Soc. Proc., 1905, 21, 179—180.

DIAZO-ANHYDRIDES of the type $X-N=N-XSO_2R$, where X

represents a phenylene or analogous group, and R an acyl group, are formed by treating monosubstituted para-diamines with nitrous acid. The following compounds have been prepared:—*Benzenesulphonyl-p-phenylenediazoimide*, *camphorsulphonyl-p-phenylenediazoimide*, *benzenesulphonyl-2,5-tolylenediazoimide*, *benzenesulphonyl-2,5-xylylenediazoimide*, and *benzenesulphonyl-1,4-naphthylendiazoimide*. Similar cyclic diazoimides could not be obtained from formyl, acetyl, succinyl and benzoyl derivatives of *p*-phenylenediamine. The formyl and acetyl compounds yielded ill-defined nitrosoamines of the type $R.CO.NH.C_6H_4.NH.NO$, whilst benzoyl-*p*-phenylenediamine when diazotised and treated with a cold aqueous solution of potassium carbonate, yielded a stable diazonium carbonate, $C_6H_5.CO.NH.C_6H_4.N_2.HCO_3$. This salt is very sparingly soluble in cold water; it forms azo compounds readily with phenols and aromatic amines, and gives benzoyl-*p*-aminophenol when boiled with acidified water. A sparingly-soluble yellow diazonium nitrite, which readily forms azo compounds, was also obtained from benzoyl-*p*-phenylenediamine. A. S.

Fisetin; Some Less Highly Hydroxylated Compounds Related to —. J. Berstein, C. Fraschina and St. v. Kostanecki. Ber., 1905, 38, 2177—2182.

FOURTEEN compounds which differ from Fisetin, 3,3',4'-trihydroxyflavonol, by the absence of one or more hydroxyl groups are theoretically possible. These had all been prepared by Kostanecki and his pupils during recent years with the exception of two compounds, namely, 3',4'-dihydroxyflavone and 3',4'-dihydroxyflavonol, which compounds have now been prepared by the authors. 2'-Hydroxy-3,4-dimethoxychalcone, prepared from veratric aldehyde and *o*-acetylphenone, was converted by boiling with alcoholic hydrochloric acid, into 3',4'-dimethoxyflavanone. This was brominated, forming a monobromo-derivative which, on boiling with alcoholic potassium hydroxide solution, was converted into 3',4'-dimethoxyflavone, which yields 3',4'-dihydroxyflavone on heating with strong hydriodic acid. This dihydroxyflavone,

dyes mordanted wool strongly, in light yellow shades on alumina mordant, and grey to black on iron mordant. 3',4'-Dimethoxyflavanone is converted by amyl nitrite and hydrochloric acid into an isonitroso-derivative which yields 3',4'-dimethoxyflavonol on boiling with dilute sulphuric acid. 3',4'-Dihydroxyflavonol, prepared by boiling the dimethoxy compound with strong hydriodic acid, has the formula

It dyes mordanted fabrics strongly, in orange-yellow shades on alumina, and grey to black shades on iron mordant. Those hydroxyflavones which dye on mordants,

yield pure yellow shades on alumina mordants, whereas the corresponding hydroxylflavonols (including Fisetin) give orange-yellow shades under these conditions. A similar difference is apparent on comparing Luteolin (1,3,3',4'-tetrahydroxylflavone) with Quercetin (1,3,3',4'-tetrahydroxylflavonol), the former yielding jonquil-yellow and the latter brownish-yellow dyings on alumina mordant. —E. F.

p-Nitrobenzene-diazonium Chloride. *Repts. Dis. Commission of* C. Schwallbe. Ber., 1905, 38, 2196–2199.

The author finds that the stability of *p*-nitrodiazobenzene solutions is much improved by the addition of neutral salts, such as common salt. This effect is most marked in the case of acetic acid solutions, containing no free mineral acid (as used for ingrain colours), which are much less stable than mineral acid solutions. The presence of free nitrous acid reduces the stability of the solutions very seriously, as does also the action of light. The decomposing action of light is greatly helped by the presence of free nitrous acid. Strong solutions, as prepared under technical conditions, are less stable than weak ones. The author states that it is possible to prepare solutions of such strength that solid *p*-nitrobenzene-diazonium salts separate out. —E. F.

α - α' -Dichloro- β - β' -dinaphthylamine. W. Schaposhnikoff and F. Göbel. Z. Farben-u. Textil-Chem., 1905, 4, 281–283.

DILUTE solutions of equimolecular quantities of quinone-dichloroaniline and β - β' -dinaphthylamine were mixed and allowed to stand at a temperature not higher than 45° C. The main product which was isolated, consisted of α - α' -dichloro- β - β' -dinaphthylamine ($C_{10}H_6.NH.C_{10}H_6.Cl$), which forms dinaphtho-carbazole on heating with quick-lime. A dyestuff was obtained as a by-product, which dyes silk in a similar manner to Safranine, and can be acetylated and diazotised. —E. F.

have been unsuccessful. On heating trimethylbasilone with phenylhydrazine, Gilbody and Perkin obtain deoxytrimethylbasilone by the removal of two atoms of oxygen, the phenylhydrazine acting as a reducing agent. However, by moderating the reaction with phenylhydrazine, the authors have obtained a nitro compound $C_{25}H_{22}N_2O_4$, which crystallises in yellow needles melting at 230°–242° C. For its preparation trimethylbasilone (one part) is heated on the water-bath with phenylhydrazine (four parts) and glacial acetic acid (10 parts). Attempts to obtain a nitro compound from tetramethylhaematoxylene have given negative results, a substance analogous to deoxytrimethylbasilone being formed, which crystallises from benzene in small white needles, melt at 170°–175° C.—D. B.

Dyestuffs: Sensitising of Properties of some New — K. Kieser. XXI., page 751.

ENGLISH PATENTS.

Colouring Matters [Azo Dyestuffs]; Manufacture of Nitro-ortho-oxazo — T. R. Shillito, London. From Aniline Colour and Extract Works, formerly J. Geigy, Basle, Switzerland. Eng. Pat. 15,619, July 19, 1904.

THE nitro-1-diazo-2-hydroxynaphthalene-4-sulphonic acid (or its anhydride) is combined with bodies of the following classes: Naphthols and their monosulphonic and carboxylic acids, aminonaphthols and their sulphonic acids, dihydroxynaphthalenes and their sulphonic acids, *m*-dihydroxybenzenes, *m*-aminophenols, and *m*-diamines. The products dye wool from an acid bath. After subsequent treatment with an alkali chromate or copper sulphate, the shades range from reddish-violet to green black. The effect of the nitro-group is to intensify the tinctorial power of the dyestuffs, and also to increase the combining power of the diazo-compound, enabling combination to be effected at a lower temperature.

Some of the results which can be obtained are shown in the following table:—

Shade of Dyeing on Wool.

Second Component.	From Acid Bath.	After Chroming.	After Treatment with Copper Sulphate.
<i>m</i> -Tolylene diamine	reddish-brown	dark-brown	dark violet
β -Naphthol	dark reddish-brown	soot-black	dark brownish-violet
2-6-Naphthol sulphonic acid (Schäffer)	blackish-violet	greenish-black	dark violet
1-5-Aminonaphthol	greenish-black	greenish-black	dark bluish-black

—E. F.

Dyestuffs: New Class of Quinoline — H. E. Besthorn and J. Hebe. Ber., 1905, 38, 2127–2129.

IN a previous communication (this J., 1904, 542) the authors described a new class of red dyestuffs, distinguished by forming strongly fluorescent solutions, and by great instability to light, which were obtained by the action of quinoline- α -carboxylic acids on the acid anhydrides of aromatic monocarboxylic acids. They now find that the same dyestuffs can be obtained in almost quantitative yields, by the action of the acid chloride of quinaldinic acid on 2 mols. of quinoline or of any quinoline derivative which is not substituted in the α -position. For instance, the quinoline cannot be replaced by quinaldine. The quinaldinic acid chloride may be replaced by the acid chlorides of other quinoline- α -carboxylic acids, but not by cinchonic acid chloride. —E. F.

Quindin and Hamatoxylin. J. Herzig and J. Pollak. Ber., 1905, 38, 2166–2168.

It has been previously shown, that trimethylbasilone and tetramethylhaematoxylene react with hydroxylamine hydrochloride to form oximes, but attempts to prepare phenylhydrazine derivatives from these compounds

Colouring Matters [Azo Dyestuffs]. Manufacture of Ortho-oxazo — from 2-Diazo-1-naphthol Sulphonic Acids. T. R. Shillito, London. From Aniline Colour and Extract Works, formerly J. R. Geigy, Basle, Switzerland. Eng. Pat. 16,566, July 27, 1904.

2-DIAZO-1-HYDROXYNAPHTHALENESULPHONIC ACIDS (or their inner anhydrides) are combined with bodies of the following groups: the naphthols and their monosulphonic and carboxylic acids, aminonaphthols and their sulphonic acids, dihydroxynaphthalenes and their sulphonic acids, *m*-hydroxybenzenes, *m*-aminophenols, and *m*-diamines. In most cases combination takes place very easily at ordinary temperature. The products dye wool from an acid bath in shades ranging from violet to bluish-black and green after subsequent treatment with alkali chromate or copper sulphate. Some of them are distinguished by fastness to light and by the beauty of the blue shades produced on subsequent treatment with copper sulphate. Some of the results obtained are shown in the following table:—

Diazo-compound from	Combined with:	Shade of Dyeings on Wool.		
		From Acetic Acid Bath.	After Treatment with Bichromate.	After Treatment with Copper Sulphate.
1-amino-1-naphthol-4-sulphonic acid	m-Amino-phenol	dark brown	black with violet tint	dark violet brown
Ditto	β -Naphthol	dark violet brown	blue black	dark violet
Ditto	1-Amino-8-naphthol-3-6-disulphonic acid	dark violet blue	green	dark blue
1-amino-1-naphthol-3-6-disulphonic acid	β -Naphthol	blackish violet	dark blue	violet
1-Amino-1-naphthol-5-sulphonic acid	1-Amino-8-naphthol-3-6-disulphonic acid	dark violet blue	green	deep dark blue

Dye-stuffs; Manufacture of Violet Sulphurised [Sulphide] —, O. Imray, London. From Farbwerke vorm. Meister, Lucius und Brüning, Hoechst-on-the-Maine, Germany. Eng. Pat. 16,269, July 22, 1904.

SEE U.S. Pat. 778,713 of 1904; this J., 1905, 83.—T.F.B.

50 per cent. Naphthazarin paste, 500 parts of water, and 22 parts of a 24 per cent. solution of sodium hydroxide are boiled together, a current of air being meanwhile passed through the mixture, until the colour has changed to a magenta tint, which occurs in three to four hours. After cooling, the new dyestuff is precipitated in brown crystals by the addition of sulphuric acid. It is soluble in water and dyes wool from an acetic acid bath in orange-red shades, which become reddish-black on subsequent treatment with a bichromate. When printed with chromium acetate on cotton, a fast, full black shade is obtained, superior to that obtained similarly with Naphthazarin. The new dyestuff is converted into a soluble compound by treatment with sodium bisulphite.—E. F.

Anthraquinone Derivatives [Anthracene Dye-stuffs]; Manufacture of New —, H. E. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 17,589, Aug. 12, 1904.

8-TRIHYDROXYANTHRAQUINONE is obtained by saponifying the sulphuric ester produced by the action of fuming sulphuric acid (or sulphuric anhydride) and boric acid on resazurin. Ten parts of the latter are added to a solution of three parts of boric acid in 200 parts of fuming sulphuric acid (80 per cent. of SO_3) at a temperature of 30° – 35° C., the mixture is maintained at this temperature until resazurin can be no longer detected in the mixture (about 4 hours); the melt is then stirred into 200 parts of sulphuric acid (60° B.), and the resulting mixture poured into water. The precipitate is dissolved in hot sodium hydroxide solution, dilute hydrochloric acid is added, and the 1.4.8-trihydroxyanthraquinone is filtered off, and may be purified by re-crystallisation from pyridine. It is soluble in sodium hydroxide solution with a violet colour, and its solution in sulphuric acid is violet-red, turning bluish-violet and showing a red fluorescence on addition of boric acid. It is stated to be a "valuable intermediate product for the production of dyestuffs."

Badische Anilin und Soda Fabrik. Fr. Pat. 349,331, Dec. 21, 1904. Under Int. Conv., March 25, and Aug. 12, 1904.

New derivatives of anthracene, termed *benzanthrones*, are obtained by condensing with glycerol, in presence of a dehydrating agent such as sulphuric acid, any of the following compounds: β-aminoanthraquinone and other derivatives of anthraquinone with an amino group in the beta position (with the exception of 1,2-dihydroxy-3-aminoanthraquinone and its derivatives), anthraquinone and its homologues and also sulphonic acids of these compounds and their reduction products, anthracene and its homologues and derivatives, and naphthantraquinone and its reduction products and derivatives. By heating the benzanthrones with caustic alkalis, with or without the addition of alcohol, dyestuffs suitable for vat dyeing and for printing are obtained. (See also this J., 1905, 192.)—A. S.

Dyestuff; ———. *Method of Preparing a Sulphide* ———. Chim. des Usines du Rhone, ancien. Gilliard, P. M. et Cartier. Ger. Pat. 158,927, Dec. 1, 1903.

By boiling dinitrosalicylic acid with alkali sodium carbonate and sulphur, (the solution being of a strength that it boils at about 120° C.) under a condenser for a long time, a valuable black dyest obtained.—T. F. B.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILE YARNS, AND FIBRES.

Fibres from British Central Africa; ———. "Denji" "Nzonogwi" ———. Bull. of the Imp. Inst., 1903, 23—25.

SAMPLES of the fibres of *Sida rhombifolia* ("Denji") and of *Triumfetta rhomboides* ("Nzonogwi") fibre) of which grow abundantly in the neighbourhood of Zomba, gave the following figures as the results of chemical examination:—

The figures for samples of *Sida rhombifolia* Bengal, and for Indian jute of "extra fine quality" (the new fibres closely resemble), are added for comparison. The fibres are considered somewhat inferior to jute in spinning qualities, and to be suitable chiefly for tow yarns. Each is valued at approximately 12l. per ton.—T. F. B.

Dyestuffs; ———. *Affinity of Artificial* ——— for Connective Tissues. Curtis and P. Le-mout. Comptes rend., 1905, 140, 1606—1608.

In preparing histological preparations a mixture of acid and Acid Magenta is frequently employed, and is used to differentiate the connective tissue very well at first, but the coloration is fugitive. The authors have experimented with substitutes for both the picric acid and Acid Magenta. They find that the picric acid may be replaced by other trinitro-derivatives, such as those of cresols, β-naphthol and resorcinol without disadvantage, and that the Acid Magenta can be satisfactorily replaced by triphenylmethane-, mono-azo- or polyazo-dyestuffs which contain at least three sulphonic acid groups, distributed, as far as possible, uniformly throughout the molecule. Under these conditions only the connective tissue is selectively dyed in a satisfactory manner. Satisfactory results were obtained with Acid Magentas and Violet Reds 4 R S and 5 R S, and also with Ponce Extra, Diamine Blue 2 B and Naphthol Black B; the latter dyestuffs offering the advantage that the results are permanent.—E. F.

ENGLISH PATENTS.

ing Agents; Manufacture and Application — J. V. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 13,955, June 20, 1904.

FORMALDEHYDE-HYDROSULPHITE compound, of sodium nature, is extracted by methyl alcohol, to obtain, on treating the filtered solution *in vacuo*, a crystalline dehydro-sulphoxylate, having a greater reducing power on indigo than the original substance, whilst the residue left undissolved by the methyl alcohol only feeble reducing power. Or the formaldehyde-hydrosulphite compound is treated with methyl alcohol; the crystals formed, of practically equal reducing power, are separated, and the solution is treated as in the previous case. Or, again, a concentrated solution of the formaldehyde-hydrosulphite compound is slowly evaporated at a gentle heat, and the crystals are separated from time to time as they form, their reducing power is tested with iodine solution, or method of obtaining the reducing compound consists in heating a formaldehyde-sodium hydrosulphite solution with zinc dust in presence of acetic acid; the precipitate by sodium carbonate, and on evaporating the filtrate *in vacuo*, a crystalline mass is obtained of sodium salt of formaldehyde-sulphoxylate acid, mixed with sodium acetate. The same product is obtained by sodium bisulphite and formaldehyde by giving a solution containing the two substances alternate additions of zinc dust and of acetic acid. After addition of sodium carbonate and giving the filtrate is evaporated *in vacuo*. The use of the agents in dyeing, and in discharging colourings from textile fibres, is claimed. (Reference is made to Eng. Pat. 3288 of 1900; 5867 of 1903; and to 7397 of 1904; this J., 1901, 247; 1904, 369; and 1905, 132, respectively. (See also Fr. Pat. 341,718 of 1904; this J., 1905, 100).)—E. S.

UNITED STATES PATENTS.

Process of Manufacturing Viscose-coated — C. N. Waite, Lansdowne, Pa., Assignor to S. W. Pettit, Philadelphia, Pa. U.S. Pat. 791,385, May 30, 1905.

AL coats of viscose are applied in succession to textile fibres, which are dried after each such application, and the viscose is "reverted." The viscose on the material may be superficially redissolved before "reverting." —B.

Waterproof, Viscose-coated — and *Process of Manufacturing same*. C. N. Waite, Lansdowne, Pa., Assignor to S. W. Pettit, Philadelphia, Pa. U.S. Pat. 738,636, May 30, 1905.

FIBRES are coated with viscose, as described in U.S. Pat. 738,636 (see preceding abstract), and are then covered with a layer of "a varnish." —E. B.

Apparatus for Dyeing — C. M. Hanson, New Bedford, R.I. U.S. Pat. 791,148, May 30, 1905.

ROTATED, rotary, cylindrical cages, serving for the treatment of textile fibres in the form of sliver, are arranged in a central, vertical shaft, above a dye-tank. The shaft has an inclined, false bottom, with a central opening closed by a dome, from which radiate liquor-conducting pipes connected with (i.) perforated pipes, which extend radially upwards close to the inner sides of the rotary cages, and with (ii.) branch-pipes, leading into perforated, vertical pipes at the centres of the cages. When the cages revolve, the dye-liquor in the tank is raised and forced into them by centrifugal action.—E. B.

Process of Making Coloured — C. Bucher, Mannheim, Germany. U.S. Pat. 790,718, May 23, 1905.

The method consists of moistening the fabric and then

progressively applying under pressure the part of a design in colour to it, and removing the pressure from the portion upon which the parts of the design have been applied, thereby producing a coloured fabric with mottled design.—T. F. B.

FRENCH PATENTS.

Textile Fibres and Threads; Coating with Cellulose or Cellulose. J. M. de Sauverzac. Fr. Pat. 349,620, Dec. 27, 1904.

TEXTILE threads, composed of fibres of either animal or vegetable origin, are passed in a continuous manner through solutions of cellulose or of colloidal substances. They are thus rendered more lustrous and thicker. Vegetable textile fibres in an unspun condition, may be united together, by means of the same solutions, to form continuous threads.—E. B.

Bleaching and Dyeing Textiles in Vacuum or under Pressure; Apparatus for — C. Crépelle Fontaine. Fr. Pat. 349,821, Nov. 26, 1904.

THE apparatus consists of an air-tight vat of suitable shape, in the top and bottom of which are situated the liquid inlet and outlet. The fabric is wound on rollers or bobbins mounted on rods, which are connected, outside the vat, with suitable means for rotating them. A number of empty rollers is provided in the vat, and the fabric is wound on these as the operation proceeds; when the latter rollers are fully wound, the driving machinery is automatically reversed, so that the fabric is rewound on the original rollers, this process continuing until the treatment is complete.—T. F. B.

Tissues, Paper, &c.; Apparatus for Printing — by means of *Sprays of Dye-stuff Solutions* [Stencil Printing]. Soc. Welting, Calisch Fils et Cie. Fr. Pat. 349,616, Dec. 27, 1904.

THE tissues, sheets of paper, &c., to be printed are drawn from a roll and intermittently passed downwards in contact with a vertical, printing table, in front of which a stencil plate is mounted so as to be capable of being strongly pressed against them. While they lie against the table, solutions of mordanting compounds, dyestuffs, &c., are applied in the form of sprays to their exposed parts. The stencil is afterwards removed, the tissues, &c., are pulled downwards to withdraw the printed portion and to substitute another portion for it. The stencil, which may be the same as was previously employed or one bearing another pattern, is then again applied, and a second length is printed as before, this procedure being repeated as often as is necessary to effect the printing of the tissue, &c.—E. B.

Aldehyde Derivatives and their Application as Discharging Agents; Production of — Badische Anilin und Soda Fabrik. Fr. Pat. 350,607, Jan. 7, 1905. Under Int. Conv., April 21 and 25, 1904.

SEE Eng. Pat. 13,955 of 1904, preceding these.—T. F. B.

Condenser for Benzene [from Dry-Cleaning Works]; *Radiating* — E. Delhotel. Fr. Pat. 349,360, Dec. 3, 1904.

THE apparatus consists of three condensing chambers, placed side by side, the first cooled by a worm condenser traversed by a current of water, and the second by the overflow from the third, which is cooled by water at a temperature of about 0° C. passing through a series of pipes. The current of hot air containing benzene, &c., *e.g.*, such as is obtained in cleaning fabrics; see Fr. Pat. 344,848 of 1904; this J., 1904, 1213) is thus cooled progressively, and the fractions which condense in the three compartments may be collected separately if desired. The cooled air passing from the last condensing chamber is led to a larger vessel, provided with any suitable means for arresting any admixed particles of benzene. The whole apparatus is surrounded by an insulating jacket. —T. F. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

UNITED STATES PATENT.

Printing upon Pyroxylin Materials: Process of —.

R. E. Roehm, Assignor to The Whitehead and Hoag Co., Newark, N.J. U.S. Pat. 791,503, June 6, 1905.

An adhesive coating is applied to the surface of the "pyroxylin material," which has previously been rendered porous, and the pattern is then printed on and allowed to dry. The material is now subjected to simultaneous heat and pressure, and the surface is afterwards suddenly chilled, pressure being maintained.—T. F. B.

FRENCH PATENT.

Tissues, Paper, &c.: Apparatus for Printing — by means of Sprays of Dyestuff Solutions [Stencil Printing].

Soc. Weidling, Calisch Fils et Cie. Fr. Pat. 349,616, Dec. 27, 1904. V., page 727.

VII.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

Alkali, &c., Works: Forty-first Annual Report on —, by the Chief Inspector. Proceedings during the year 1904, &c. Feb. 27, 1905. Price 8d.

Works scheduled as alkali works show a reduction of two as compared with 1903; but other works subject to registration have increased by eight. There have not been any prosecutions under the alkali acts for the year dealt with. The "Alkali, &c., Works Bill, 1904," was withdrawn under pressure of time in August last, but will be, it is expected, re-introduced in the coming session. There has been increased demand for salt-cake, though not for chlorine products. The production of chlorine for bleaching powder manufacture in different countries, by the electrolytic and Leblanc processes respectively, is quoted from Hasenclever as follows:—

	Electrolytic.	Leblanc.
	Per cent.	Per cent.
Germany	65	55
England	18	82
France	19	81
America	100	—
Austria	66	34
Spain	100	—
Russia	55	45
Belgium	54	46

Of the total 260,000 tons of bleaching powder produced by the world, half is stated to be contributed by electrolytic methods, and the other half by methods having hydrochloric acid as their source.

Experiments in treating the acid discharges from the chimneys of alkali-waste works with alkaline waste slurry described in the Report for the preceding year (this J. 1904, 784) have been continued, but under somewhat changed conditions, the residual gases entering the absorbing towers at a much higher temperature than before. Under these circumstances difficulties arose: "the carbonator waste assumed an extraordinary gelatinous physical condition, so much so that it was necessary to revert to the use of carbonated waste itself in the absorbers in place of alkaline raw waste slurry." The function of the waste, at this higher temperature, was limited to neutralisation of the sulphurous acid portion of the gases, the hydrogen sulphide portion being unaffected. A table is given showing details of the relative efficiency of the raw and the spent slurry used, as derived from laboratory experiments.

The average amount of acid gases escaping from sulphuric acid works for the year covered by the Report, is slightly under that of the preceding year, and none of the 168 works concerned has given serious cause for anxiety,

although there have been occasions for protests, involving temporary stoppages of plant.

Further experience has been gained in the past year to details of the lead chamber process for the manufacture of sulphuric acid, especially in reference to securing tightness of draught and in the replacement of steam by finatomised water. The statement of C. R. Alder Wright is quoted and italicised, that the normal action of a vit chamber "does not go on in virtue of the interaction one another of gaseous or vaporous substances solid but takes place on the surface of the liquid water vesicles formed by the partial condensation of the steam at the moment of its entering the chamber," and it is inferred that "the greater part of the steam blown in must precipitate as vesicles of liquid water mist immediately on entering the chamber; and that the chemical changes "largely go on at the surface of the floating vesicles." (See C. R. Alder Wright, this J., 1904, 1178.) In respect to any desirability of enquiry as to the sources of the loss of nitre in the chamber system, the chief inspector directs attention to the new method introduced by Mr. Inglis, in his paper on "The Loss of Nitre in the Chamber Process" (this J., 1904, 643-5), of freezing the exit gases and subjecting the product to fractional distillation, whereby it has been shown that only a small proportion of the losses are attributable to formation of nitrous oxide. In one sulphuric acid factory in Scotland, Dr. Meyer's tangential system, in which the chambers are cylindrical or drum-shaped, the gases entering at the top of the drum tangentially, and being withdrawn at the bottom from the centre, have been introduced. The initial difficulties met with in the process have been overcome. In contact processes for sulphuric acid manufacture, there has been no extension; but at one of the works the conditions of successful application of dilute milk of lime for reducing the acidity of the exit gases run down a coke-packed scrubber have been studied. It is found necessary to arrange that the milk of lime should not settle until it enters the top of the tower, and it is therefore delivered from a tank supplied with an agitator and a constant stream of water, into "a trough in which is an air-pipe to the bottom, compressed air keeping the lime from settling. Four or five pipes from this trough deliver into four or five smaller troughs in which also are air-pipes delivering compressed air." The milk of lime flows from several openings in these smaller troughs to the lutes on the top of the tower.

The Kessler process for rectifying sulphuric acid continues to give satisfaction. In a recently developed process of concentration, rectification has been effected at a lower temperature by blowing heated air through the acid in the concentrating vessel.

The increased demand for sulphuric acid free from arsenic, has directed the attention of manufacturers to the precautions necessary in the use of hydrogen sulphide for precipitating arsenic from the acid. An explosion (happily without loss of life) occurred at a factory, attributed to contact of an explosive mixture of hydrogen sulphide and air with the scaly iron oxide on the pipe leading to the lime purifier. The ignition is presumed to have been caused by the rapid sulphiding and re-oxidation of the iron oxide. In the case referred to, the iron pipe was subsequently replaced by a lead pipe.

In chemical manure works, the manufacture of superphosphate is practically dependent on imported material, of which the amounts, in tons, are:—

	1904.	1903.	1902.
Guanos	24,276	28,000	9,000
Muriatic phosphates	419,221	392,714	365,000
Nitrate of soda	120,526	115,000	105,000

The exports of ammonium sulphate in 1904 were 177,000 tons, the home consumption being 68,500 tons as against 162,300 tons and 71,700 tons respectively for the preceding year. The manufacture of superphosphate in Belgium, largely for export to this country, is to a great extent dependent upon the supply of crude sulphuric acid pro-

ced as a bye-product of the spelter works, the activity which have increased of late, there, as well as in Silesia in the United States.

In gas-liquor and ammonium sulphate and chloride works, account is given in the Report of numerous points at which the working is liable to go wrong, unless under official supervision. A fatality, involving the loss of 6 lives, occurred at the Batley Corporation Gas Works, due to a mistake in the order of closing and opening the re-vivifying apparatus in the foul-gas branch pipes. It is stated that "the Claus sulphur recovery plant has advanced value now that the recovery of cyanogen ducts is being undertaken at many of the larger gas works." Gas-liquor sometimes contains a very notable portion of ammonium cyanide, and attention is directed to the necessity of precautions against poisoning, owing to the presence of hydrocyanic acid gas in the gaseous ducts evolved.

Under the heading "Recovery and Production of ammonia," the following table is given:

Amount of Sulphate of Ammonia Produced in the United Kingdom:—

	1904.	1903.	1902.
1 works	150,208	149,489	150,055
2 works	19,568	19,119	18,801
3 de works	42,486	37,353	36,931
4 ce oven works	20,848	17,438	15,352
5 ducer gas and carbonising			
6 works (bone and coal) ...	12,880	10,265	8,177
Total	245,990	233,664	229,316

There has been considerable extension of the application of ammonia recovery to coke oven plants, an extension which will probably be still greater in the current year. A table is given showing the analyses of ammoniacal liquors from two different sources, in one of which a proportion of cyanide is exceptionally large. There is a further Memorandum from Mr. Linder respecting the Analysis of Ammoniacal Liquors," supplementary to that given in the Report for the preceding year. Field's method of estimation of thiocyanate (thiocyanate) and thiosulphate (this J., 1903, 1068) in these variations, is followed, and the results are summarised in two tables, a third table being given of details of the estimation of ferrocyanide. Certain precautions are to be observed, one of which is that in the thiosulphate present must be exactly oxidised to tetrathionate by the iodine used.

This process has been applied, with certain precautions, in the following cases:—Ferrocyanide alone present; ferrocyanide and thiocyanate both present, organic matter absent; and ammonium ferrocyanide in gas-works liquor. In the first case, either hydrochloric or sulphuric acid may be used to decompose the mercuric cyanide in a final distillation; in the second and third cases, the best results are obtained when sulphuric acid is used. Attempts to quantitatively estimate ferrocyanide as Prussian blue (method given in detail) did not afford satisfactory results.

In salt works, gaseous fuel from Mond producers fitted for ammonia recovery, has been applied with good effect, the salt obtained being of good quality and colour. It is further intended to utilise the steam evaporated from the brine as a source of supply of water vapour to the producer itself. The output of white salt and salt contained in brine used in the ammonia-soda process was, in 1903, 1,719,223 tons, as compared with 731,688 tons in 1902. There is an increase in the output of coke oven works in which producer gas manufacture is accompanied by ammonia recovery. In one of these works, the purified gas is used for the production of electrical energy in an engine of 1000 h.p. of the Oechelhauser type, in which a cylinder with open ends is provided with two pistons moving in opposite directions, the charge being compressed by their approach on the return stroke, so that a fresh impulse is given by explosion on every revolution of the shaft. Such gas engines have

been successfully used at Hörde in Germany. In connection with blast-furnaces using coke, a large quantity of the Société Cockerill type to compress the blast, is worked by the gases coming from the plant for the recovery of ammonia. The effluent gases are singularly free from fixed impurities.

There has been depression in the cement manufacture, both at home and in Germany, lower prices practically supplies her own needs. The use of the rotary kiln is extending, and the smoke nuisance is being minimised by the improvements introduced.

The production of arsenic continues to diminish, with the final closing of operations at Devon Great Consols. The chief inspector states that "with increasing demand for tungsten for alloying steel, wolfram is now especially valuable: it occurs associated with molybde, and is first calcined for separation of arsenic by volatilisation."

Although in the production of zinc no electrical process has as yet succeeded in (generally) supplanting the old-established processes, yet one such process, that of Höpfer, forms the basis of operations whereby the metal is obtained from blende at one factory, from which no nuisance proceeds, the earlier difficulties encountered having been overcome.

Part III of "Studies of the Claus Kiln Reaction," is given under the heading "Influence of the various Contact Substances on the Interaction of Steam and Hydrocyanic Acid," (A) in absence of hydrogen sulphide and air; and (B) in presence of these bodies. Under (A), experiments were made using as contact material, broken brick, iron oxide, and Weldon mud, of which the latter exerts a "much more powerful oxidising action upon the reaction-products than oxide of iron, no carbon monoxide or hydrogen surviving." Under (B) the three contact materials named were tried. Generally, the presence of hydrogen sulphide and air favours a high yield of ammonia under certain conditions of temperature for the several contact substances used. With respect to the presence of ammonium sulphate in the sulphur recovered from Claus kilns in gas-liquor works, and its relation to the nitrogen entering with the saturator gases in the form of hydrocyanic acid, the paper appearing in this J., 1904, 586, is referred to. The results of further experiments are given in tabular form, accompanied with descriptions of processes and apparatus.

The Report consists of 155 pages, of which 11 pages are devoted to Scotland.—E. S.

Sulphuric Acid Manufacture; Equilibrium in the Contact Process of —. M. Bodenstein and W. Pohl. Z. Elektrochem., 1905, 11, 373—384.

RESEARCHES undertaken to ascertain whether the reaction in the contact process obeys the law of mass-action, i.e., whether (C being the concentration)

$$\frac{C_{SO_2}^2 C_{O_2}}{C_{SO_3}^2} = K \text{ a constant, dependent}$$

on temperature only, not on the proportions of the reacting gases, their dilution with inert gas, or the nature of the catalyst. Knietzsch, in his report to the 1903 Congress of Applied Chemistry, gave the results of some measurements indicating a constant value for K, but only for one mixture and for almost complete conversion; and Bodländer and v. Köppen's measurements (this J., 1903, 1128), were restricted in range of temperature, and lacked the necessary exactness to decide the question. The authors have adopted a method similar to that of Knietzsch, passing a steady stream of sulphur dioxide and air or oxygen, or both, over platinum in a quartz tube heated by an electric furnace, and determining the composition of the mixture before and after contact. Extreme care was taken to keep the composition of the mixture constant during the whole time of an experiment, to secure as nearly as possible uniformity of temperature throughout all parts of the hot tube, to ascertain that temperature accurately, to maintain it constant, and to prevent alteration of the composition of the gas in its passage from the catalytic chamber to the absorption tubes in which it was analysed.

The experiments of the first series, 14 in number, were carried out at 727° C. (1000° Abs.). The actual variations of temperature in the different experiments were from 998 to 1003° C.; but after the results of the later series were obtained, it became possible to apply a correction, which gave the value of K at 1000° in each case. The pressure varied from 753 to 770 mm.; the amount of sulphur dioxide present with 1 vol. of oxygen varied from 0.21 to 3.97 vols.; in some of the experiments there was also present nitrogen to the extent of 3.76 vols. per vol. of oxygen; the speed of travel varied from 5.4 to 53.4 c.c. per minute; and in one of the experiments the apparatus was so arranged that the amount of sulphur trioxide formed in the first portion of the catalytic apparatus was greater than that ultimately present, so that equilibrium was reached from the other direction. The amount of sulphur trioxide formed, expressed as percentage of the original dioxide, varied from 20.8 to 59.6; and the value of K varied only from 3.42×10^{-3} to 3.67×10^{-3} , averaging 3.548×10^{-3} .

A number of shorter series of experiments at different temperatures were then undertaken, and showed in all cases most satisfactory concordance among the individual results. The average results of the whole are tabulated below:—

Temp. C.	Value of $K \times 10^3$	Temp. C.	Value of $K \times 10^3$
528	1.55	727	354
579	7.55	789	1260
627	31.6	832	2800
680	112.0	897	8160

The correctness of these values is confirmed by the fact that the heat-evolution of the reaction $2\text{SO}_2 + \text{O}_2 = 2\text{SO}_3$ calculated from them agrees well with the determined value, and that the specific heat of gaseous sulphur trioxide deduced from them ranks amongst those of similar gases. The values of K , however, determined by Knietseh and by Bodländer and v. Köppen do not agree at all well with those of the authors. Probably in Knietseh's case errors in the determination of the temperature account for the difference; were his temperatures too high by amounts varying from 15 to 70°—quite a possibility, as the difficulties of fixing and determining it are so great—his results would agree with those of the authors'. Lunge and Reinhardt are in agreement, as close as the nature of the case allows, with the authors. The conclusion is that this reaction obeys the law of mass-action closely, and may indeed be chosen with advantage from among other reactions as illustrating and demonstrating the operation of the law.

The authors have also calculated from their results, and embodied in the following tables, the yields (per-

Composition by Volume.

—J. T.

Sodium Carbonate and Hydroxide; Densities of Solutions of —, R. Weischeder and H. Walter. Mon. Chem., 1905, 26, 685–725.

The following determinations were made of the densities at 60° and at 80° C. of solutions of sodium carbonate, of sodium hydroxide (always containing some sodium carbonate), and of mixtures of the two:—

Gram-Equivalents per Litre.			Percentage by Weight.		Density (Wat. at 4° C.)
Na ₂ CO ₃ .	NaOH.	Total.	Na ₂ CO ₃ .	NaOH.	
7.027	—	—	28.74	—	1.21
5.960	—	—	25.20	—	1.21
5.111	—	—	22.25	—	1.21
4.036	—	—	18.23	—	1.17
2.988	—	—	14.06	—	1.13
0.142	6.938	7.080	0.61	22.57	1.27
0.108	6.018	6.126	0.48	20.04	1.20
0.078	4.976	5.054	0.35	17.04	1.10
0.082	4.018	4.100	0.38	14.16	1.11
0.074	3.007	3.081	0.36	10.92	1.10
3.660	3.348	7.008	15.38	10.63	1.20
3.198	2.923	6.121	13.79	0.52	1.22
2.725	2.474	5.199	12.10	8.29	1.17
2.178	1.986	4.164	9.965	6.86	1.11
2.056	1.927	3.983	9.47	6.70	1.11
1.618	1.453	3.071	7.69	5.22	1.11
6.900	—	—	28.59	—	1.22
3.995	—	—	18.26	—	1.10
0.127	6.951	7.078	0.55	22.81	1.27
0.088	3.927	4.015	0.42	14.01	1.12
3.598	3.480	7.078	15.26	11.14	1.22
2.040	1.975	4.015	9.48	6.93	1.11

The following results were obtained by weighing a measured quantity in a graduated pipette at 11° C., measuring the expansion, and hence calculating the density at 80° C.:—

Gram-Equivalents per Litre.			Percentage by Weight.		Density.	
Na ₂ CO ₃ .	NaOH.	Total.	Na ₂ CO ₃ .	NaOH.	At 11°5.	At 80°
6.866	4.207	5.073	3.845	14.10	1.196	1.157
6.706	4.020	4.726	3.171	13.63	1.182	1.142
6.483	3.631	4.114	2.204	12.51	1.164	1.126
6.351	2.879	3.230	1.642	10.17	1.136	1.097
6.060	4.923	4.983	0.269	16.64	1.186	—

centage of SO_2 converted into SO_3) for different mixtures and at different temperatures:—

Composition by Volume.				Temperature.					
Air.	N ₂	SO ₂	O ₂	400	500	600	700	800°	900°
<i>Stoichiometric Mixture, with Nitrogen.</i>									
—	0.0	66.67	33.33	98.4	91.3	76.3	51.5	30.1	16.0
—	79.00	14.00	7.00	99.3	84.7	62.2	35.2	18.3	8.2

Interpolation formulæ were calculated, by which the densities of all solutions of sodium carbonate and hydroxide of concentrations up to 8N, for all temperatures between 0° and 100° and between 15° and 80° C. respectively, could be calculated. The formulæ giving results agreeing most closely with the determinations of the authors are those previously published by others were for carbonate:—

$$d_t = d_{(w)} + (0.05534 - 0.0001273t + 0.000000867t^2)N_t \\ - (0.0012244 - 0.00000859t + 0.0000000507t^2)N_t^2 \\ \text{or} \\ d_t = d_{(w)} + (0.0111726 - 0.00003918t + 0.000000232t^2) \\ + (0.000016956t + 0.0000007272t^2 - 0.00000000478t^3)N_t$$

hydroxide

(w) is the density of water at the given temperature; n is the number of gram-equivalents per litre and percentage by weight of the substance. Formulae for densities of mixed solutions can be calculated from the formulae

$$d = d'' + \frac{(d' - d'') N'}{N}$$

N is the total number of gram-equivalents per litre and d'' the densities respectively of sodium hydroxide and sodium hydroxide solutions of that "normality" and N' the "normality" in sodium carbonate solution (so that $N - N'$ is its "normality" in hydroxide). These formulae do not apply with accuracy to all solutions, but for details of the cases the original must be consulted.—J. T. D.

es; Reduction of —. C. Brückner. *Monatsh. f. Chem.*, 1905, 26, 675—682.

The author has examined the phenomena of reduction of the sulphates when heated with magnesium powder, carefully excluding. The alkali sulphates give sulphur dioxide under these circumstances; but, sulphide, thiosulphate and polysulphide are always in the products. The alkaline-earth sulphates, those of magnesium, zinc, aluminium and nickel, of sulphur dioxide, and there remain sulphide, phosphate, and polysulphide of the metal, together with free sulphur and, of course, magnesia. The behaviour of copper sulphate is similar, save that cuprous and metallic copper are always among the products. Ferrous and manganous sulphates leave no metallic higher oxide, along with the products of reduction. Iron takes place to some extent with most of these when they are merely rubbed in a mortar with magnesium powder. In this case sulphide is the only product. Magnesium reacts on sulphur trioxide, promagnesia and magnesium sulphide, and liberating sulphur dioxide.—J. T. D.

ium Chlorate; Conversion of — into Iodate, means of Iodine in presence of Nitric Acid. M. Söster. *Z. angew. Chem.*, 1905, 45, 270—274.

The progress of the reaction depends upon the concentration of the nitric acid. If that be low, the chief reaction occurring is that of Ostwald:—

With high concentrations, Thorpe and Perry's reaction: $2\text{KClO}_3 + \text{I}_2 = 2\text{KIO}_3 + \text{Cl}_2$ takes place almost exclusively, if the proportions of chlorate and of iodine be appropriate. With excess of iodine, however, chlorine is produced instead of chlorine: $\text{KClO}_3 + \text{I}_2 + \text{ICl}$. The conversion of chlorate into iodate is effected in this way with quantitative exactness for analytical purposes.—J. T. D.

ENGLISH PATENTS.

Furnaces for Use in the Manufacture of Soda, for the Smelting of Metals, and for like purposes; Engls. Pat. —. H. L. Wrinkle, Thebe, and N. Wrinkle, Koeler, both of California. *Eng. Pat.* 15,792, July 15, 1904.

The furnace is built for use with fluid or pulverised fuel, and is formed with a melting chamber having tangential tuyères, and an upright shaft having at the top a charging hopper and bell, and outlet conduits on opposite sides for the passage of waste gases. The crucible or melting chamber has a lower dome constituting its top, and an upper dome which supports the shaft (both removable), the space between the domes forming an air chamber, in which is a radial partition serving to deflect the air-blast led into it. The air thus heated leaves the chamber on the opposite side of the partition to that by which it enters, and passes into a pipe half-surrounding the furnace, and thence to the tangential tuyères through which the liquid fuel is injected. The crucible is so constructed that the material charged into it from the stack takes the form of a truncated cone, affording an unobstructed passage for the burning gases which reverberate from the sides upon the mass of the charge. The arrangements for mechanically discharging the furnace material are shown as adapted to a soda-manufacturing furnace; but may be modified by addition of a fore-hearth with separate means for tapping off slag, when the furnace is used for smelting metals.—E. S.

Alkalis; Manufacture of Dehydrated Caustic —. J. V. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. *Eng. Pat.* 4762, March 7, 1905.

Sodium or potassium hydroxide, or a mixture of these, hydrated, but solid at ordinary temperatures, is dehydrated by moderate heating in a vacuum. An iron vessel may be used. Reference is made to *Eng. Pat.* 12,320, 1895.—E. S.

Ammonia; Process for the Production of —. H. C. Wolfreck, London. *Eng. Pat.* 16,504, July 26, 1904.

See *Fr. Pat.* 345,399 of 1904; this *J.*, 1904, 1215.—T. F. B.

UNITED STATES PATENTS.

Hydrohalogenic Acid [e.g., Hydrochloric Acid]; Process of Making —. F. W. Westhauser, Stuttgart, Germany. *U.S. Pat.* 791,306, May 30, 1905.

HYDROCHLORIC acid is produced by bringing a moist mixture of its "components" into contact with aluminium chloride under the influence of heat. In more general terms, the process for the production of a hydrohalogenic acid consists "in conducting a mechanical mixture of its components in a humid condition and under the influence of heat over porous bodies charged with decomposable corresponding halogenides of metals."—E. S.

Sulphuric Anhydride; Catalytic Apparatus for Making —. G. Eschellmann and A. Harmuth, Assignors to Tov. Tentelevskago Khimichesk Zavoda, St. Petersburg. *U.S. Pat.* 792,205, June 13, 1905.

See Addition of Oct. 4, 1904, to *Fr. Pat.* 321,275 of 1902; this *J.*, 1905, 277.—T. F. B.

Oxides of Alkaline Metals; Apparatus for Obtaining —. G. W. Roepper and W. E. Harmar, Assignors to Amer. Electrolytic Co. *U.S. Pat.* 790,922, May 30, 1905. *XLII.*, page 738.

Ammonia; [Electrical] Process of Manufacturing —. W. Hoopes, Pittsburg, Pa. *U.S. Pat.* 791,194, May 30, 1905.

An aqueous solution of an ammonium salt is electrolysed in the cathode compartment of a cell having a porous diaphragm, whilst the anode compartment is charged with sodium chloride, or other chloride than ammonium chloride. The ammonia and hydrogen produced at the cathode are separated, and the hydrogen is combined with chlorine.—E. S.

FRENCH PATENTS.

Aluminium Hydroxide; Calcination of. —, Comp. des Prod. Chim. D'Als et de la Camargue. Fr. Pat. 349,709, April 8, 1904.

The calcination of aluminium hydroxide for the production of anhydrous alumina, suitable, for instance, for use in obtaining aluminium by electro-metallurgical processes, or for lining furnaces, is found to be greatly facilitated by the addition to the hydroxide of a small proportion, such as 1 per cent., or less, of a fluoride. Preferably, the fluoride is added as ammonium fluoride; or the aluminium hydroxide may be moistened before calcination with hydrochloric acid. The calcined product is stated to retain, at most, only traces of fluoride.—E. S.

Calcium Phosphate Minerals containing Calcium Carbonate; Process of Treating. —, A. Gaudet and F. Gernaert. Fr. Pat. 349,715, Dec. 29, 1904.

MINERALS composed of calcium phosphate together with calcium carbonate, but comparatively free from aluminous compounds, such as might form double silicates under the intended treatment, are mixed with silica, and, if not previously calcined, also with an agglutinant, preferably with calcined calcium phosphate. The moistened mixture is agglomerated into bricks, which, after drying, are roasted at a high temperature, to induce the formation of calcium silicate from the calcium carbonate present. The product is treated with an acid, preferably with dilute sulphuric acid, in proportion to form phosphoric acid or soluble compounds of the same, and calcium sulphate, the silicate remaining unattacked.—E. S.

Nitrates; Process for Preparing. —, Aktieselskabet det Norske Kvælstofkompagni. Fr. Pat. 350,619, Jan. 9, 1905. Under Int. Conv., Jan. 22, 1904.

Carbon Dioxide; Process of Manufacture of Liquid. —, Mdme Syssoyeff, né Fischer, and C. Cheynet. Fr. Pat. 349,416, March 24, 1904.

A STRONG reservoir, communicating on one side with a series of iron bottles, adapted for holding liquid carbon dioxide, and on the other with another strong vessel containing moistened sodium carbonate, is charged with a

milk of chalk and with an aqueous solution of sodium bisulphate. Connection being made to the bottles, which are suitably cooled, the carbon dioxide evolved collects in them. The charge is renewed as often as may be necessary to attain a stated pressure, when the connection bottles is cut off, and the current of gas is directed into the vessel containing sodium carbonate, the latter cooled. When the sodium carbonate is converted into bicarbonate, the vessel is put into communication with the bottles, and heat is applied to it until the absorbed carbon dioxide is driven off and collected as desired, with recovery of sodium carbonate.—E. S.

Carbon Monoxide; Apparatus for the Detection and Determination of. —, A. Lévy and A. Pecou. Fr. Pat. 349,714, Dec. 29, 1904. XXIII., page 71.

VIII.—GLASS, POTTERY, AND ENAMELS.

UNITED STATES PATENT.

Glass; Process of Manufacturing. —, C. Ellis, Assignor to Eldred Process Co., both of New York, N.Y. U.S. Pat. 792,123, June 13, 1905.

THE raw materials for making glass are heated to high temperature by means of combustible gas. The gaseous products of the reaction are withdrawn from the furnace and passed, together with air or oxygen, if necessary, through a deep bed of fuel to produce a combustible gas, rich in hydrogen, owing to its low contents of nitrogen and carbon dioxide, of high calorific value.—A. G. L.

IX.—BUILDING MATERIALS, CLAY MORTARS, AND CEMENTS.

Lime-sand Bricks; Influence of added Fine Sand. —, M. Glascenapp. Tonind. Zeit., 1905, 29, 689—690.

IN order to increase the conversion of calcium hydroxide into hydrosilicate, and thus minimise the waste caused by the presence of the former in the finished product, it is advisable to replace a portion of the ordinary sand by some in a more finely divided condition. Thus, a mixture of 97 parts of dune sand and three parts of lime as a standard, the substitution of three parts of fine quartz powder for an equal weight of sand, increases the dissociation of silica by 8.38 per cent., five parts of quartz powder giving an increase of 16.76 per cent. in the case of a mixture containing 6 per cent. of lime; the corresponding figures were 11.88 per cent. and 23.56 per cent. respectively. Similar results have been obtained

large scale by Seger and Cramer, the use of 3 per cent fine quartz powder increasing the crushing strength of the bricks by 58 per cent. A further advantage is that the bricks are (theoretically at least) better able to resist the action of fire, the free lime or calcium oxide being a special source of weakness under the action of high temperatures.—C. S.

Purifying — C. Lorenz. *Tonind.-Zeit.*, 1905, 29, 621.

By sedimentation is the best means of eliminating impurities, since any lime, marl, or pyrites present are rushed and more widely distributed in the mass mills are used, the result being deterioration of the whole batch. In any event, before deciding on the use of a purifier to use, the clay should be subjected to a test, to determine whether mills or washers should be used.—C. S.

Portland Cement; Constitution of — from a Physico-chemical Standpoint. C. Richardson. Association of Portland Cement Manufacturers, Atlantic City, N.J., 15, 1904.

It is well-known that the mineral constituents of rocks can be identified under the microscope, in thin sections, and with the aid of polarised light, and these petrographic methods have been applied to sections of Portland cement clinker. In this way Le Chatelier and Tönnemann identified four constituents, which were named *alite*, *celite*, and *felite*, and are recognisable by their optical properties. The author has synthesised the compounds which might exist in Portland cement, mono-, di-, and tricalcium silicates, and mono-, di-, and tricalcium aluminates, and tricalcium di-silicate. Definite compounds of iron and lime and magnesia exist, but are not essential to the formation of clinker, and the author has also found that definite mineral entities such as occur in industrial Portland cement, but solid solutions of aluminates in silicates, a consideration of the theory of solid solutions, the author concluded that Portland cement might be a solid solution of aluminates in tri-calcium silicate, and the essential constituents of clinker, what are their components and are they in a structure like steel, a solid solution of carbon in iron, at a definite temperature.

Analyses were made from pure silica, alumina, and lime in the proportions found in industrial clinker. From exact analyses of clinker, the relative number of molecules of the different substances was calculated, the molar proportion of iron being added to the alumina, similarly the proportions of the lime and other bases, and the relative amounts of silica, alumina and lime calculated to give a clinker of the same basicity and molar ratio, but with the unessential elements absent, the lime present in combination with sulphuric acid being deducted. From the amounts thus arrived at, it was found in No. 1, that after deducting three molecules of lime for combination with silica as tri-calcium silicate, the amount of lime left for combination with alumina was not closely with the formula $2\text{Al}_2\text{O}_3 \cdot 3\text{CaO}$, in No. 2, a quantity insufficient to form even a monomeric salt was left, which necessitates the conclusion some di-calcium silicate must be present. Sections of clinkers thus prepared showed that No. 1 contained both *alite* and *celite*, and was not therefore a homogeneous solid of the aluminate $2\text{Al}_2\text{O}_3$ in tri-calcium silicate; in No. 2 a larger amount of *celite* was present. Clinkers made in which the different aluminates were present in certain definite molecular ratio to the tri-calcium silicate. That in which the monocalcium aluminate was present contained the most *celite*, while that in which the di-calcium aluminate was present in a tri-calcium form contained the most *alite*. Hence this constituent is a solid solution of di-calcium aluminate in tri-calcium silicate, and *celite* di-calcium aluminate in di-calcium silicate, since tri-calcium silicate and di-calcium aluminate would react to yield di-calcium aluminate with a corresponding reduction of tri-calcium to di-calcium silicate. In these experi-

ments the ratio of silicate to aluminate was varied, and taking the ratios 3 to 1, 1 to 1, and 5 to 1, the amounts of *alite* and *celite* can be calculated, and also the amount of lime on the ratio of silicate to aluminate, and on the composition of the clinker as a whole. The extreme composition of an industrial cement within the limits of the above ratios, if the cement is perfectly burned, would be as follows:

Silica	18.5	23.2
Alumina (R_2O_3)	6.1	11.9
Lime (without magnesia and alkalis)	63.1	65.1

When the *celite* is rich in aluminate, the cement was found to be quick-setting, and probably the rate of cooling affects the amount of *celite* formed. An increase of lime in the cement No. 1 would have given an increased amount of *alite*, and the cement was actually found then to be slower setting. Cement No. 2, containing 1 per cent. less alumina, is a much less concentrated solution of aluminates in silicates, but on the other hand is less basic, and contains a larger amount of dilute *celite*. For the first reason cement No. 1 should be slower setting, but for the second the latter clinker would be less "volume constant," since *celite*, being a di-calcium silicate solution has the characteristic lack of volume constancy. The terms "mild," "medium" and "hard" are suggested for cements with increasing amounts of aluminate, by comparison with steels with increasing amounts of carbon.

To test the concentration of aluminates in silicate within which the clinker exists as a normal Portland cement, series of clinkers were prepared with varying amounts of tri-calcium silicate and tri-calcium aluminate or of tri-calcium silicate and di-calcium aluminate, to determine the effect of a reduction of lime and consequent increased formation of *celite*, and of di-calcium silicate and di-calcium aluminate. The results obtained are complicated, and the mineral entities occurring in the clinkers vary with the concentration towards either silicate or aluminate. In the second or "cement" series the Portland cement ratio was found to extend from—

	SiO_2	Al_2O_3	CaO
Pure tri-calcium silicate	26.4	0.0	73.6
To 7 ($\text{SiO}_2 \cdot 3\text{CaO}$), 3 ($\text{Al}_2\text{O}_3 \cdot 2\text{CaO}$)	18.9	13.6	67.5

Beyond this concentration, the clinkers lose the characteristic structure of Portland cement, although they are hydraulic.

It is evident that basic silicates and aluminates are miscible in all proportions in the fused condition, but not so in a state of solid solution. *Alite* and *celite* are solid solutions—but not saturated—of aluminates in silicates, and the question arises how these solutions are formed during the conversion of raw materials into clinker, at temperatures below the fusion point. From the fact that diffusion occurs not only in gases and liquids, but also in solids, it is not difficult to understand that particles of silica, alumina, and lime may diffuse at a temperature below the melting point of the resulting clinker to form a Portland cement, the stability of which depends partly on its composition, and partly on the completeness of the diffusion. The time of exposure of the materials to the high temperature should be longer the lower the temperature. Further, the raw materials must be ground fine enough to provide a sufficient area of intimate contact for diffusion to be complete at the given temperature and in the allotted time; otherwise the resulting clinker will not be homogeneous in constitution, and therefore not in equilibrium, and will lack volume constancy. Again, just as aqueous solutions can be made supersaturated, so silicate of lime may dissolve more aluminate at high temperatures than will remain in solution on cooling, and such a solution would be in a state of tension, and tend to return to equilibrium with a change of volume, and the liberation of some aluminate, which may explain the change of rate of setting, with age, observed in some cements. If raw materials are ground sufficiently fine, a satisfactory clinker may be produced at a lower temperature, and consequently the greatest economy will depend upon a proper balance between fineness of grinding and fuel expenditure, the balance depending upon the cost of

fuel. The longer time of burning required in the dome kiln, is probably due to the fact, that diffusion occurs more slowly than in the rotary kiln. The higher the percentage of lime, the higher the temperature required for complete diffusion with silica, and the greater the necessity for fine grinding. —W. C. H.

ENGLISH PATENTS.

Kilns, Stoves, and the like; Process and Apparatus for Purifying them, and for Separating the Constituents thereof. R. Eugner, Lamoges, France. Eng. Pat. 21,199, Nov. 8, 1904. Under Int. Conv., Nov. 9, 1903.

SEE Eng. Pat. 336,490 of 1903; this J., 1904, 372. —T. F. B.

Covers, Blocks and Slabs; Manufacture of Non-Conducting — suitable for Covering Steam Pipes, Boilers and the like and for other Purposes. H. C. Michell, London. Eng. Pat. 25,787, Nov. 26, 1904. Under Int. Conv., Nov. 27, 1903.

A MIXTURE of flake mica and a silicious binding agent, *q.p.*, sodium silicate solution, with or without the addition of asbestos or other refractory fibre, is moulded, dried, heated to about 1000° C., and cooled slowly. The flakes of mica should be arranged, as far as possible, parallel to one another and at right angles to the direction in which heat is passing from the article to be protected. —A. G. L.

Covers, Blocks and Slabs; Manufacture of Non-Conducting — suitable for Covering Steam Pipes, Boilers and the like and for other Purposes. H. C. Michell, London. Eng. Pat. 25,788, Nov. 26, 1904. Under Int. Conv., Nov. 27, 1903.

A MIXTURE of asbestos and a silicious binding agent, such as sodium silicate, is moulded, dried, and heated to a high temperature, say about 1000° C., in order to effect combination between the asbestos and the binding agent. Mica or other light filling material may be added to the mixture according to Eng. Pat. 4970 of 1901. —A. G. L.

UNITED STATES PATENT.

Brick or Artificial Stone; Process of Making — L. F. Kwiatkowski, New York, N.Y. U.S. Pat. 790,901. May 30, 1905.

INGREDIENTS including lime and sand are mixed and the lime is hydrated. The mixed material is placed in a V-shaped receptacle in "layers of different ages," and after a certain time, portions of each layer are removed from the bottom and moulded together. —A. G. L.

FRENCH PATENTS.

Pumice; Process for the Agglomeration of Natural and Artificial — Soc. Geoffroy, Jacquet et Guillermin. Fr. Pat. 349,618, Dec. 27, 1904.

THE pumice to be agglomerated is mixed with silicates or fluosilicates, or both, either in the form of solutions or of powders, with the addition of enough water to give a plastic mass. This is moulded, dried in the air, or by a gentle heat and burnt at a dark red heat. —A. G. L.

Wood-Composition; Manufacture of — F. Matas y Rols. Fr. Pat. 349,782, Dec. 31, 1904.

THE composition consists of wood sawdust or shavings, with a solution of nitrocellulose in methyl alcohol as binding agent. The mass is agglomerated in heated moulds under pressure; the heat causes the individual particles of wood to distend, so that they are forced against each other not only by pressure from the outside,

but also by pressure from the inside of each piece. The moulds consist of perforated metal sheet or gauze; pressure is preferably exerted simultaneously in two directions at right angles to each other in order to ensure a uniform product. Ether or acetone is added to the methyl alcohol solution in order to increase its rate of evaporation, if desired. Gum arabic is added to the mass to retard evaporation and to render the product more coherent. The nitrocellulose solution may be altogether replaced by a solution of animal vegetable glue or similar material. —A. G. L.

Wood; Process of Impregnating — E. B. Fr. Pat. 350,758, Jan. 14, 1905.

Agglutinant Suitable for use in the Manufacture of Moulded Objects, and also for other Purposes. L. and E. Perry. Fr. Pat. 349,839, Dec. 31, 1904.

SEE Eng. Pat. 21,842 of 1903; this J., 1905, 198. —T. F. B.

GERMAN PATENTS.

Tiles [for Decorative Purposes]; Manufacture of — A. Biberfeld. Ger. Pats. 157,383, Dec. 6, 1902; 158,612, Sept. 23, 1903; and 158,613, Jan. 13, 1904.

THE tiles are prepared by forming crystals of sugar (sugar-candy) on a backing of textile material of suitable size and shape. According to Pat. 158,612, other catalisable substances, such as alum, rock salt, copper sulphate, ferrous sulphate, &c., are substituted for the sugar in Pat. 157,383, and the tiles so prepared are coated with celluloid, collodion, lacquer, varnish, or the like. According to Pat. 158,613, tiles prepared according to Pat. 157,383, are also coated with celluloid, lacquer or the like. —A. S.

Solid Articles, Pipes, or the like from Moist Peat; Process for the Manufacture of — F. Stötzel. Ger. Pat. 159,651, March 19, 1903.

PEAT, either in its natural moist condition or in which a portion of the water has been removed by pressing, is mixed with cement in such proportions that the hardening of the mass is effected by the moisture contained in the peat. For the manufacture of drain-pipes, a suitable quantity of tar or asphaltum is added to the mass. —A. S.

Stone; Process for the Manufacture of Artificial — from the Residues of Paper Manufacture. O. Wendt. Ger. Pat. 159,615, Aug. 14, 1903.

THE residue obtained as a by-product from paper-making machines, containing chloride of lime, alum, caustic soda, residues of vegetable glue, and various colouring matters, is ground, mixed with organic substances such as sawdust, sawdust, &c., and a refractory binding agent such as clay, moulded into the desired forms, dried and burnt. —A. S.

Tiles, &c.; Process for the Manufacture of — from Slate or Slate Waste. Aktieselskabet Ardeise. Ger. Pat. 158,364, Oct. 25, 1903.

THE slate powder is mixed with from 5 to 8 per cent. of powdered chalk and formed into tiles with the aid of a binding agent consisting of rosin soap and water (alkali silicate solution) with or without the addition of kaolin. The binding agent is prepared by boiling three parts by volume of powdered caustic soda and 16 parts of powdered rosin with 30 parts of water, and adding to the mixture one part by volume of kaolin, 10 parts of water and 30 parts of sodium silicate. The tiles are formed by the aid of a pressure of 15–40 kilos. per sq. cm. and allowed to stand for some days at the ordinary temperature, dried for about three days at 60°–100° C., glazed and baked at 800°–1000° C. —A. S.

X.—METALLURGY.

Effect of — in Low-Silicon Cast Iron. H. Londenbeck. Trans. Amer. Foundrymen's Assoc., J., 1905, 17—19.

NESE can be used to advantage in low-silicon and iron (a) where the percentage of scrap is large and phur high; (b) when plates having hard chilled and soft backs are desired; (c) when the amount of r in the iron employed exceeds 0·07 per cent.

he manufacture of large hydraulic cylinders, the nese should be kept low, otherwise the casting may coarse graphitic structure which is very unsatis-. The following analyses are given of cylinders ick:—

—J. H. C.

Melting — with Cast Iron. R. P. Cunningham. Trans. Amer. Foundrymen's Assoc., June, 1905, 8—10.

ther states that by a judicious use of steel scrap, s can be produced of any required strength, but that lose attention is required in charging the proper ties of materials, fuel, and fluxes. For thin castings little steel can be used; for thick, heavy castings mere is permissible. It is an advantage to use a rro-silicon and ferro-manganese unless the iron used is manganese and silicon in fair proportions. The of 18 casts with different percentages showed that ore than 33 per cent. of steel could be used with age, as above this proportion there was excessive age and only a slight gain in strength. For ry work 25 per cent. of steel is recommended. The st in the middle of each heat were always the best.

—J. H. C.

and Cobalt; Alloys of —, with Iron. W. Guertler G. Tammann. Z. anorg. Chem., 1905, 45, 205—224.

ron used in making the nickel- and cobalt-steels ned was very pure; that for the nickel-steels con- 0·06 per cent., and that for the cobalt-steels 0·24 nt. of carbon. The *nickel-steel melting point curve* ts of two branches, with a discontinuity at 35 per cent of nickel (1510° C.); the curve for alloys higher in descends from this to a minimum at 66 per cent.) and gradually rises thence to the melting-point of ickel (1485°), whilst the curve for alloys lower in remains at about 1500° down to 20 per cent., and gradually rises to the melting-point of iron (1550°). 6 per cent. alloy corresponds to Ni₃Fe, and, being an of minimum m. pt., ought to crystallise out leaving a r-liquor of the same composition; but this property e to characterise the whole of the nickel-iron alloys, solidify as a whole, whatever their composition, ag crystal-mixtures of Ni₃Fe with nickel or with where the nickel exceeds 35 per cent., and solutions kel in γ -iron where it falls below that percentage. ination of the magnetic permeability shows that the r cent. limit divides the reversible steels containing r nickel from the irreversible containing less. In the r, the temperature at which magnetisation occurs on ag is identical with that at which it disappears on ag; in the latter, supercooling occurs, and magnetisa- does not appear till far below the temperature at

which it is lost on heating. The authors' determination of these critical temperatures agree very closely with those of Osmond, the differences being no doubt caused by the different amounts of minor constituents present in Osmond's steels and in the authors'. Apparently both nickel and Ni₃Fe undergo on cooling a transformation from a β - to an α condition. The *cobalt-steel melting-point curve* is practically a horizontal line at 1500° C. from 100 per cent. to 5 per cent. of cobalt, and below that rises to the melting point of iron. Like the nickel-steels, the cobalt-steels of every composition show no separation of constituents on solidifying. In regard to transformation on cooling (as shown by change of magnetic permeability) they group themselves into four classes:— 1. From 100 to 75 per cent. of cobalt, reversible, changes on heating and on cooling occurring at the same temperature. 2. From 75 to 60 per cent., the change occurs not suddenly but over an interval of about 100°, which interval is between the same temperatures whether the temperature is rising or falling. 3. From 60 to 5 per cent., irreversible, a supercooling of 20°—30° making that difference between the transformation-temperatures on heating and on cooling. 4. Below 5 per cent., the transformation-temperatures on heating and on cooling are on first heating almost identical, 760°—752° C., but on repeated heating the former gradually rises to 820°, while the latter remains constant.

All these alloys exhibit when polished and etched a polygonal structure, varying greatly in distinctness and in the size of the polygons; the authors have not yet, however, been able to draw from the micrographic examination of these alloys any conclusions as to their constitution.—J. T. D.

Silver; Cyanidation of —. A. Chidley. Eng. and Mining J., 1905, 79, 1053.

THE ore treated contains argentite, chalcopyrite and, occasionally, specks of tetrahedrite; a small quantity of copper is also present, but has no injurious effect on the extraction of gold and silver. The ground ore is passed over amalgamated plates and then separated roughly into sand and slime by settling. The sand is mixed with lime in the proportion of 25 lb. per ton and treated for 12 hours with nearly one-half of its weight of a 0·4 per cent. solution of cyanide. After draining off the solution, the charge is raked and levelled, allowed to stand exposed to the air for six days, then leached continuously for four days with a 0·2 per cent. solution of cyanide, and washed with water. The sand contains from 13 to 15 oz. of silver and from 3 to 5 dols. of gold per ton, and the average extraction is 85—90 per cent. of the silver and 90—92 per cent. of the gold.—A. S.

Aluminium; Alloys of —, with Tin, Bismuth, and Magnesium. H. Pécheux. Comptes rend., 1905, 140, 1535—1536.

THE action of water on these alloys (see this J., 1904, 609 and 716) has already been noticed by the author, and he has recently demonstrated it on a larger scale, having obtained in 20 minutes, from 2 c.c. of the filed tin alloy, 5—6 c.c. of hydrogen. The bismuth alloy yielded more hydrogen than the tin alloy, and the magnesium alloy more than the bismuth alloy. The oxygen of the decomposed water combines with the aluminium. Larger quantities of hydrogen are obtained from copper sulphate solution, apart from the decomposition of this solution by precipitation of copper at the expense of the metal alloyed with the aluminium. The alloys of aluminium with zinc and lead do not decompose pure water, but do decompose the water of copper sulphate solution, and, more slowly, that of zinc sulphate solution.—J. T. D.

Copper; Corrosion of — in Sea-Water. Uthemann. Engineer, 1905, 99, 442—443.

IN the following table the results of some tests of the author's method of protecting copper by means of a spiral of iron wire from corrosion by sea-water (see Eng. Pat. 21,661 of 1904; this J., 1905, 623), are given:—

b, are secured at the points at which a spiral drawn
the centre of the vessel intersects those arms, and
the ends of the paddles are set at one and the same angle

ward to their radii, and so arranged that the leading
of any blade traces out the same path as the outer
edge of the preceding one, except the blade of the
last paddle *b*, which is turned towards the outer wall
of the vessel. The two outermost blades project into
the vessel, extending round the edge of the bottom of the
vessel. Mercury and the crushed ore-pulp are delivered
to the revolving paddles, and the metallic particles
are thrown towards the outer wall, gravitate into the
space in which amalgamation is effected. The amalgam
concentrates are drawn off through a tap, whilst the
residue is led to a shoot.—E. S.

for use in the Manufacture of Soda, for the
refining of Metals, and for like purposes: Impts. in—
E. and N. Wrinkle. Eng. Pat. 15,792, July 15, 1904.

2, 1904.

U.S. Pat. 779,037 of 1905; this J., 1905, 138.—T. F. B.

UNITED STATES PATENTS.

Manufacture of — J. Vernon, Newton Stewart,
Scotland. U.S. Pat. 791,170, May 30, 1905.

Eng. Pat. 1966 of 1903; this J., 1904, 609.—T. F. B.

Chinese-Steel Rails or Shapes: Manufacture of —
A. Hadfield, Sheffield, England. U.S. Pat. 791,189,
May 30, 1905.

Billets or blanks are heated gradually to about 880° C.,
and then afterwards rapidly to about 950° C. They are then
immediately worked to the desired section, reheated as
necessary, and quickly quenched.

In casting the ingots, the upper ends are cast with larger
heads than the lower ends and with large feeding heads.
The feeding heads are then removed and the billets are
drawn to the required section from the lower solid and
sound portions of the ingot.—J. H. C.

and Steel; Process of Treating Ferruginous Ore
for the Manufacture of — therefrom. M. Moore,
Melbourne, and T. Heskett, Brunswick, Australia.
U.S. Pat. 791,928, June 6, 1905.

U.S. Pat. 341,169 of 1904; this J., 1904, 827.—T. F. B.

and Steel; Apparatus for Treating Ferruginous
Ore for the Manufacture of — therefrom. M. Moore,
Melbourne, and T. Heskett, Brunswick, Australia. U.S.
Pat. 792,440, June 13, 1905.

U.S. Pat. 345,599 of 1904; this J., 1905, 32.—T. F. B.

Nickel: Extraction of — H. A. ...
U.S. Pat. 791,090, May 30, 1905.

The mattes or other nickel-bearing substances are re-
duced to powder, mixed with sulphuric acid, and
heated.—J. H. C.

Ore: Process of Smelting — E. Riveroll, Los Angeles,
Cal. U.S. Pat. 791,577, June 6, 1905.

The ore is delivered down an inclined covered passage
leading from the base of the stack to a vessel into which
the reduced molten metal flows. At intervals in the arched
cover of the channel, jets of burning fluid fuel are injected,
the supply of air being so controlled that the ore in the
upper part of the inclined channel is deoxidised by exposure
to a flame depositing carbon on it, and also to the action
of carbon monoxide gas, produced from the ore in the
lower part of the passage, where it is exposed to a smelting
heat by means of a "perfect combustion flame."—E. S.

Ore-Briquette. W. A. Kōneman, Chicago, Ill. U.S. Pat.
791,799, June 6, 1905.

The claim is for briquettes composed of a mixture of
"ore-fines," finely divided, bituminous coal and anthracite
to which a binding agent is added. The mixture is formed
into briquettes and dried without allowing the coal to
become coked. The dried briquettes are charged into a
blast-furnace, where they are coked during the initial
heating, the ore particles, which were formerly held
together mechanically by the binding agent, being now
bound together by the coked coal.—W. H. C.

Furnace; Roasting — F. Klepetko, New York.
U.S. Pat. 792,053, June 13, 1905.

Is a furnace having one or more hearths, claim is made
for a vertical, hollow rabble-shaft, having horizontal
hollow rabble-arms projecting from it. On the inner
surface of each rabble-arm, parallel to the longitudinal
axis, is a series of ribs, by means of which the cooling
medium, (air), drawn into the arms from the hollow shaft,
is split up into a number of individual currents.—A. S.

Furnace; Rotary [Ore] — W. S. Rockwell, Assignor
to Rockwell Engineering Co., New York. U.S. Pat.
792,169, June 13, 1905.

SEE Eng. Pat. 1503 of 1904; this J., 1904, 443.—T. F. B.

Furnace; Metallurgical — J. W. Lansing, San
Francisco, Cal. U.S. Pat. 792,223, June 13, 1905.

The plant consists of a combination of a number of up-
right furnaces, each having an ore-chamber with a fire-
box beneath, a closed receptacle containing water, and a
stack, together with the necessary connections. In the
upper portion of the closed receptacle, above the level of
the water therein, is an exhauster, which draws the gases
evolved in the ore-chambers into the receptacle, beneath
the surface of the water. A continuous flow of water
into and out of the receptacle is maintained. The exit
passages from the fire-boxes lead to the stack, and
dampers are provided by means of which the fire-gases
may be diverted from any one of the ore-chambers at
will.—A. S.

Copper [and Copper Alloys]; Process of Hardening and
Tempering — C. R. Plumer, Seattle, Wash.
U.S. Pat. 792,070, June 13, 1905.

COPPER or a copper alloy is heated to a high temperature,
treated while hot with copper sulphate, and poured into
moulds. After partial cooling, the metal is subjected
to the action of sulphur until it is coated with "sulphur-
oil," and then allowed to harden.—A. S.

Alloy: Antifriction Composition or — and Process for its Manufacture. L. Boudreaux. Fr. Pat. 349,459, March 26, 1904.

THE invention (as to its main features) consists in the agglomeration of finely-divided metals, with in most cases a lubricating material, into blocks under pressure. Such metallic powders are obtained by a variety of methods, adapted to special cases; such as by reduction of the oxides or salts (of copper for example) by heating with carbon; by precipitation from solution, by for instance zinc powder, (or copper, antimony, tin and lead); by electro-chemical means; or by condensation of the vapours, as with zinc; always with precautions to ensure that the powders obtained be extremely finely-divided, constituting a "sponge" having a "molecular porous or crystalline structure," suitable to enter into combination, of the kind above indicated, with lubricating substances, which may be in the form of powders, pastes or liquids. Graphite may be so used, being added before or during the compression of the powdered metals into blocks. Also, during compression of the powdered metals, substances may be added, capable of subsequent removal as vapour by heat, or by solution in a suitable medium, leaving the block with a porous structure, analogous to that of platinum sponge. Numerous applications of such antifriction powders or alloys to mechanism in movement are specified and claimed.—E. S.

Ores: Process and Apparatus for the Separation of — on Shaking Tables by the aid of Water. Maschinenbau-Anstalt Humboldt. Fr. Pat. 349,689, Dec. 9, 1904.

IT is proposed by varying the inclination of the washing tables according to different methods, to regulate the force of the currents of washwater.—J. H. C.

Amalgamator for Gold and Silver Ores. B. A. Langridge. Fr. Pat. 349,832, Dec. 31, 1904.

SEE Eng. Pat. 28,490 of 1904; this J., 1905, 335.—T. F. B.

Gold from Water Containing it; Process and Apparatus for Extracting —. H. C. and U. Ciantar. Fr. Pat. 350,668, Jan. 10, 1905. Under Int. Conv., Jan. 11, 1905.

GERMAN PATENTS.

Steel and Steel-Alloys: Process for the Manufacture of Mild — in the form of Castings. F. Siewert and A. Thomas. Ger. Pat. 159,474, Sept. 19, 1903.

THE mild steel or steel heated considerably above its melting point is poured into the moulds, in which are suspended rods or plates of the substance which it is desired to alloy with the steel. The alloying substance is melted by the heat of the molten steel, and the ebullition which takes place causes a thorough mixing of the metal.—A. S.

Metals: Process for the Manufacture of Alkali, Alkaline-earth, Earth and Heavy — or of Alloys of these Metals. J. Malovich and Co. Ger. Pat. 159,632, Aug. 14, 1902.

OXIDES or salts of the metal or metals are mixed with the sulphate or sulphite of another metal, a reducing agent and sulphur, and the mixture is heated to a temperature above the melting point, but below the volatilisation point of the metal or alloy it is desired to obtain. For example, a mixture of 100 parts of aluminium silicate (brick dust), 33 parts of sodium sulphite and 11 parts of sulphur is heated in a crucible for 5—7 hours at 800°—900° C., whereby metallic aluminium and a vitreous slag are stated to be obtained.—A. S.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Cell for Industrial Laboratories; Standard —. Rosset. L'Eclair. Electr., Paris, 1904, 40, 449. Proc. Inst. Civil Eng., 1905, 159, 71.

THE Daniell cell is the most suitable one for industrial laboratories, but its E.M.F. which is dependent upon degree of concentration of the solutions of zinc and sulphates, is subject to variations, owing to changes in these concentrations caused by diffusion, evaporation, chemical action of the zinc, and electro-deposition of copper. In order to overcome this defect, the inventor proposes the employment of equimolecular solutions of zinc and copper sulphates, separated by a semi-permeable membrane of copper ferrocyanide formed in the cell by an ordinary porous pot. By the use of the Daniell cell the strengths of the two solutions are maintained equal, and in these circumstances, the E.M.F. of the cell and the thermal co-efficient remain constant, independent of the absolute concentrations of the solutions.—

Combustion of Organic Compounds; Electrical Method for the —. H. N. Morse and L. S. Taylor. U.S. Pat. 792,022, June 13, 1905.

ENGLISH PATENT.

Insulating Material and Process of Manufacture of the same; Electric —. J. Billwiller, Goldach, and P. Karrer, Moriken, Switzerland. Eng. Pat. 27,194, Dec. 27, 1904.

UNITED STATES PATENTS.

Furnace; Electric —. E. Haagen, Assignor to W. C. Heraeus, both of Hanau, Germany. U.S. Pat. 792,022, June 13, 1905.

ONE terminal of the source of electric current is connected to a conductor leading to the heating or melting chamber of the furnace, the second terminal being connected to another conductor, which enters a recess in the side of the furnace and reaches nearly to the inner surface of the melting chamber. A second conductor leads from the heating chamber also to the recess, and the two terminals in the recess are joined by a rod made of a metal, the melting point of which is a little above a red heat; the rod may be observed from the outside of the furnace, and indicates "by its commencing red heat" the correct strength of the current.—B. N.

Furnace; Electric —. F. A. J. FitzGerald and P. M. Bennie, Niagara Falls, N.Y. U.S. Pat. 792,251, June 13, 1905.

THE furnace comprises a base, with apertures in which a heat-insulating material is disposed, and a number of independent compartments on the base. The compartments are separated by hollow walls of refractory material, within which are placed resistances, connected electrically in series and also connected with an auxiliary terminal.—B. N.

Oxides of Alkaline Metals; Apparatus for Obtaining —. G. W. Roepper, Philadelphia, Pa., and W. E. Brier, Mechanic Falls, Me., Assignors to American Electrolytic Co., Delaware. U.S. Pat. 790,922, May 30, 1905.

AN apparatus for mercurial alkaline processes consisting of a transferring wheel (for effecting circulation of mercury) mounted transversely in the de-amalgamating compartment, and dipping below both the water and the amalgam. The wheel is fitted with peripheral pockets containing loose pieces of electrically-conductive material held in position by wire gauze round the periphery of the wheel. Perforated plates forming circumferential compartments are also provided to divide the pockets into smaller compartments and facilitate the discharge of the alkaline amalgam.—G. W. McD.

Electrolysing Salt Solutions with the Use of a Liquid Cathode; Method of ——. R. F. Anderson. Ger. Pat. 158,590, Dec. 2, 1902.

The mercury cathode is kept in motion by applying to the outside of the electrolytic cell the poles of a powerful electro-magnet.—T. F. B.

Electrode; Nickel —, for Use with Alkaline Electrolytes. M. Roloff and H. Wehrlin. Ger. Pat. 159,393, June 7, 1903.

A PASTE, suitable for coating nickel electrodes for use in processes in which alkaline electrolytes are used, is prepared by precipitating with alkali a solution containing 5 mols. of a nickel salt and 1 mol. or less of a silver salt. These electrodes are said to have a higher specific capacity than those containing more silver than is indicated above.—T. F. B.

Oxides or Hydroxides of Metals mixed with Graphite in the form of Granules; Product obtained from — for Electrolytic Processes with Invariable Electrolytes. Kölner Accumulatorenwerke Gottfried Hagen. Ger. Pat. 158,800, Oct. 17, 1903.

The granules of graphite are electrolytically coated with a thin shell of some easily conducting metal, which is not attacked by the electrolyte, and are then worked up into a paste with metallic oxides or hydroxides for plates of electric apparatus in which an invariable electrolyte is employed, the object being to increase the conductivity of the resulting paste.—T. F. B.

Chlorates of the Alkalies or Alkaline Earths; Process of Preparing — by Electrolysis. H. Landolt. Ger. Pat. 159,747, May 31, 1904.

By the addition of a small quantity of bleaching powder solution to the chloride solution in the electrolytic production of chlorates, the cathode becomes covered with a film of lime, which prevents reduction of the chlorate at the cathode, whilst the hypochlorous acid generated at the anode assists in the oxidation of the chloride. Two litres of a clear solution of bleaching powder, containing 50 grms. of available chlorine per litre, are added to 100 litres of saturated sodium chloride solution, and the mixture is electrolysed, at a temperature of 80–100° C., by means of a current of 1000 amperes per sq. m. of cathode surface. Further addition of bleaching powder solution (300–500 c.c. per 100 litres of electrolyte) is necessary every 24 hours or so. By this method, it is stated that solutions containing 600–700 grms. of sodium chlorate per litre are ultimately obtained.—T. F. B.

(B).—ELECTRO-METALLURGY.

Copper and Zinc and their Cyanide Solutions; E.M.F. between —; and their Behaviour on Electrolysis. F. Spitzer. Z. Elektrochem. 1905, 11, 345–368.

THE E.M.F. which copper and zinc exhibit in cyanide solutions is dependent on the concentration of the solution and its content in free potassium cyanide. In both cases, higher concentration of the metal cyanide and greater excess of free potassium cyanide give rise to a larger potential difference, but with copper the effect is much more marked than with zinc. As a result, zinc, which in dilute alkali cyanide solutions is a less noble metal than copper, just as it is in most other salt solutions, in very concentrated potassium cyanide shows a smaller P.D. than copper.

That copper and zinc mutually precipitate each other from the corresponding cyanide solution, is ascribed to the formation of alloys, since the results are not in accordance with the above potential measurements.

The yield in the electrolytic deposition of zinc and copper from cyanide solutions is greatly influenced by the current density and content in free cyanide, which must both be

kept very low, as otherwise hydrogen is evolved at the cathode, and very little metal is deposited. In the electro-deposition of brass, the alloy is obtained at a potential which is far below that at which pure zinc could be deposited.—R. S. H.

Copper; Effect of Impurities on the Electrical Conductivity of —. L. Addicks. Bull. Amer. Inst. Mining Eng., May, 1905, 559-568.

THE author's experiments were made with a view of determining the amounts of various elements which would lower the electrical conductivity of copper by 3 or 4 per cent. The results obtained are shown in the following table. —

Element Added.	First Sample.			Second Sample.			Third Sample.			Fourth Sample.

ENGLISH PATENT.

Metals; Solutions for the Electro-deposition of —. L. Potthoff. New York. Eng. Pat. 14,058, June 21, 1904.

THIS invention relates to an electrolytic bath for the deposition of metals, and is composed of a mixture of equal parts of an aluminium salt and a salt of the coating metal, dissolved in water to form a solution having a density of from 11 to 18 B. When a double salt of aluminium is not used, about 2 per cent. of an organic acid or 4 per cent. of a carbohydrate is added. The bath may also be made from a mixture of 5 to 8 per cent. by weight of an aluminium salt, with from 25 to 50 per cent. of a salt of the coating metal, dissolved in about 100 parts of water.—B. N.

UNITED STATES PATENTS.

Gold or other Diamagnetic Metals; Art of Separating [Electrically] —. L. T. Weiss, New York. U.S. Pat. 791,305, May 30, 1905.

THE diamagnetic particles are first electrolytically coated with a magnetic metal, and the coated metallic particles are then separated from the accompanying matter by magnetic means.—E. S.

Metals; Electrolytic Deposition of —. H. C. Harrison, London, and J. Day, Weston-super-Mare. U.S. Pat. 791,341, May 30, 1905.

Furnace; Electric —. P. Girod. Second Addition, dated Dec. 24, 1904, to Fr. Pat. 329,822 of Feb. 28, 1903 (this J., 1903, 1054 and 1904, 1225).

THE modification, described in this addition, relates to a form of furnace containing a number of independent crucibles; the base of the furnace is either in one piece or lattice-like in character, and the top is covered with several removable refractory plates. The heating is effected as described in the main patent and in the first addition.—J. N.

Galvanising, Tinning and Coating Wire and other Metallic Bodies; Process of —. G. A. Goodson. Fr. Pat. 349,664, Dec. 29, 1904. Under Int. Conv., Jan. 9, 1904.

SEE Eng. Pat. 3798 of 1905; this J., 1905, 550.—T. F. B.

Sulphides, Antimonides and Arsenides; Treatment of —. N. H. M. Dekker. Fr. Pat. 349,730, Dec. 30, 1904.

THE powdered minerals are suspended in acidulated water, and treated with nascent hydrogen and oxygen produced by the electrolysis of water. The hydrogen unit with a portion or the whole of the sulphur, antimony, or arsenic, whilst by the action of the oxygen, sulphates (or antimonates or arsenates) or oxides are produced. The apparatus employed consists of a rectangular vessel containing fixed and revolving electrodes.—J. H. C.

Electrostatic Separation [of Ores]; Method and Apparatus for —. C. H. Huff. Fr. Pat. 350,601, Jan. 7, 1905.

SEE Eng. Pat. 27,449 of 1904; this J., 1905, 282.—T. F. B.

Copper; [Electrical] Process for Colouring —. M. J. Fr. Pat. 350,508, Jan. 3, 1905.

THE copper article is made the cathode in a bath containing a potassium cyanide solution of an arsenic or antimony salt and iron chloride, the anode being an iron plate, and the current is passed until a film of arsenic or antimony is formed upon the copper. The coated article is then removed and heated to redness. It is stated that the copper article thus treated acquires a brilliant enamel-like resistant coating of a red or violet tint.—E. S.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Test [Fatty Acids]; Co-operative Work on the — Assoc. of Official Agric. Chemists, 1904. U.S. pt. of Agric., Bureau of Chem., Circular No. 22, 1905.

The result of experiments by a number of chemists agree independently on the titer test, the following conclusions are drawn:—(1) The method of preparing the acids has no influence on the results. (2) The fatty acids should be dry; filtering, and heating for 20 minutes at 40° C. is recommended. (3) The varying results are chiefly due to differences in the method of drying the fatty acids during the test. (4) The Wolfbaur method of stirring gives the best results (see this J., 1894, 8). (5) A standard thermometer should be used.—A. S.

Hydrocarpus Wightiana and Hydrocarpus Anthelmintica; Constituents of the Seeds of —. Isolation of a Homologue of Chaulmoogric Acid. F. B. Power and M. Barrowcliff. Chem. Soc. Proc., 1905, 21, 175–176.

Seeds of *H. Wightiana* yielded 32.4 per cent. of a fatty expression, and 41.2 per cent. by extraction with ether. The expressed oil had the following characters:—*n*_D²⁰, 22°–23° C.; sp. gr. at 25° C., 0.958; [*a*]_D²⁰ in chloroform, + 57.7°; acid value, 3.8; saponification value, 207; iodine value, 101.3. From the seeds of *anthelmintica* 16.3 per cent. of oil was obtained by expression, and 17.6 per cent. by extraction with ether. The expressed oil had the following characters:—*n*_D²⁰, 25° C.; sp. gr. at 25° C., 0.953; [*a*]_D²⁰ in chloroform, 2.5°; acid value, 7.5; saponification value, 212; iodine value, 86.4.

The two oils resemble very closely chaulmoogra oil. *Taraktognos Kurzii* (this J., 1904, 669) both in physical characters and in composition. They consist of the glyceryl esters of chaulmoogric acid, $C_{32}O_2$, and a new acid, *hydrocarpic acid*, $C_{16}H_{32}O_2$, a homologue of the same series, which has also been isolated from chaulmoogra oil. Hydrocarpic acid crystallized from alcohol in glistening leaflets, melting at 60° C., having [*a*]_D²⁰ = +68° in chloroform. It is an unsaturated acid, but contains only one ethylenic linkage, therefore possesses a closed carbon ring. Besides the constituents mentioned, the oil of *H. Wightiana* contains a very small proportion of an acid or acids of the linolenic series, whilst the oil of *H. anthelmintica*, on the other hand, contains small quantities of oleic and palmitic acids.—A. S.

Gynocardia Odorata; Constituents of the Seeds of —. F. B. Power and M. Barrowcliff. Chem. Soc. Proc., 1905, 21, 176–177.

Power and Gornall (this J., 1904, 669) have previously shown that the oil from *Taraktognos* seeds is identical in physical character and chemical composition with the chaulmoogra oil of commerce. The results of the present investigation now show conclusively that the oil known in European commerce as "chaulmoogra oil" and sometimes "gynocardia oil" could not have been obtained from seeds of *Gynocardia odorata*, as was generally believed to the year 1900. Chaulmoogra oil is a solid at the ordinary temperature (*m. pt.*, 22°–23° C.), is optically active, and consists chiefly of the glyceryl esters of acids of the chaulmoogric series, whereas the oil from *Gynocardia* seeds is a liquid at the ordinary temperature, is optically inactive, and contains neither chaulmoogric acid nor its homologues.

Gynocardia seeds yielded, on expression, 19.5 per cent., by extraction with ether, 27.2 per cent. of an oil having a light yellow colour, and an odour resembling that of linseed oil. The expressed oil had the following characters:—Sp. gr. at 25° C., 0.925; acid value, 4.9; saponification value, 197; iodine value, 152.8. It consists of the glyceryl esters of the following acids:—Linolenic acid, or isomerides of the same series, constituting the largest proportion of the oil; (2) palmitic acid in considerable amount; (3) linolenic and *iso*-linolenic

acids, the latter preponderating; and (4) oleic acid in relatively small amount. (See also this J., 1905, 558.)—A. S.

Cod Liver Oil and other Fish Liver Oils: A Comparative Study of —. R. T. Thomson and H. Dunlop. Paper read before Assoc. Pub. Analysts of Scotland, June, 1905, 1–18.

THERE is a close correspondence between the density value and refractive index in fish liver oils, and the latter is, therefore, regarded by the authors as only affording corroborative evidence. The saponification value is not of much use as a differentiating test with the exception that dog-fish oil has a very low value (e.g., 169.7), corresponding with its high proportion of unsaponifiable matter, whilst porpoise blubber oil has an exceptionally high value (256.6), indicative of the presence of volatile fatty acids. The amount of unsaponifiable matter in seven different fish-liver oils, including cod-liver oil was low (1.0 to 1.38 per cent.), whereas dog-fish oil contained 8.4 per cent., and shark liver oil 15.28 per cent. In the authors' opinion it is at present impossible to differentiate between cod, ling, coal-fish, hake, whiting, haddock and skate liver oils, whilst the detection of small proportions of seal or whale oil or even of dog-fish or shark liver oils in cod liver oil is very difficult, though probably less than 5 per cent. of porpoise oil could be detected. As regards the Pharmacopœia tests for cod liver oil, the authors consider that the range of the iodine value should be extended to 181, and that the sp. gr. should range from 0.923 to 0.931, whilst the unsaponifiable matter should not exceed 1.5 per cent.—C. A. M.

UNITED STATES PATENT.

Oil; [Paint—] and Paint, and Process of Making same. W. N. Blakeman, jun. U.S. Pats. 792,113 and 792,114, June 13, 1905. XIII.A., page 742.

FRENCH PATENT.

Castor Oil Product Miscible with Mineral Oil; Preparation of a —. Soc. Anon. Française Stern-Sonneborn pour la Fabrication des Vaseline, Huiles et Graisses Industrielles. Fr. Pat. 350,511, Jan. 3, 1905.

CASTOR oil is heated for six hours in an autoclave at a temperature of 260–300° C. and under a pressure of 4–6 atmospheres. When cold, the resulting product mixes in all proportions with mineral oil.—W. P. S.

GERMAN PATENTS.

Fatty Acids; Process for the Recovery of Fat from Soap, Effluents and the like, in the form of —. F. Kaepfel. Ger. Pat. 159,170, Jan. 20, 1903.

THE fat contained in the material is saponified, the soap is extracted by hot water, and the fatty acids are precipitated from the hot soap solution in the usual manner, and extracted by a suitable solvent in order to separate them from albuminoid substances.—A. S.

Fatty Acids and Resins; Process for the Saponification of — by means of Alkali Carbonates. W. Heckhausen. Ger. Pat. 158,929, April 27, 1904.

FATTY acids and resins are saponified by means of alkali carbonates in a closed vessel under pressure, the gases evolved being led first into an air-chamber, and then to the purifying apparatus. It is claimed that by the aid of the air-chamber, which acts as a pressure-regulating device, the saponification can be effected under pressure, without risk of danger from the sudden evolution of considerable quantities of carbon dioxide.—A. S.

Soap. R. A. Jones. Ger. Pat. 159,098, Oct. 1, 1903.

CLAIM is made for a tablet of soap, a portion of which is covered with a protective coating, e.g., paraffin wax. A mark or label may be impressed on the soap before it is coated with the paraffin.—A. S.

Soap: Process for Preparing Tablets, &c., of — enclosed in Casings. W. Rödiger i. F. Kluge und Co. Ger. Pat. 158,572, Oct. 2, 1903.

THE process is intended for the preparation of tablets, &c., from soap which is liquid when hot, but becomes solid on cooling. The soap whilst still in a liquid or pasty condition is filled into casings, such as cardboard boxes, paper bags, &c. Thus, the usual cooling process before packing the soap is dispensed with.—A. S.

XIII.—PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS, PAINTS.

Paints and Colours containing Lead: Report on the Manufacture of — as affecting the Health of the Operatives employed. T. M. Legge, H.M. Medical Inspector of Factories. 1905. [Cd. 2466.] Price 11½d.

IN consequence of the severe incidence of lead poisoning (as coming under section 73 of the Factory and Workshops Act, 1901), to persons employed in paint works, nearly 100 such factories, in London, Liverpool, Glasgow, Hull, Manchester and Birmingham, have been inspected. An analysis of 225 cases of "plumbism," from January 1, 1899, to June 30, 1904, brings out very prominently the injurious effect of the inhalation of dust containing lead, for whilst operations which can be generally classed as "wet processes" are responsible for only 18·2 per cent. of the cases, no less than 72·9 per cent. are traceable to dust. From returns furnished by District Inspectors of 148 paint works in which the grinding of white lead is carried on, it appears that in only 16 has any attempt been made to control the dust arising during the transference of the white lead from the casks to the grinding machinery, and the remarks made by the Certifying Surgeons show that the dust arising in that operation affects men at work in the immediate neighbourhood not themselves handling lead products. Dust containing lead also arises from the operations of sifting and packing red-lead, vermilionettes, chrome greens and yellows, though the risk of poisoning from these colours seems to be far less than that from white lead. The wet processes produce but few cases, though some severe ones have occurred in carrying out a process involving prolonged boiling of the materials, there being evidence that the spray projected into the air during ebullition has an injurious effect similar to that of dust. The wearing of respirators is open to many objections, and the whole investigation points to the necessity of employing exhaust draught to draw away the dust from the worker. An Appendix to the Report embodies the definite suggestions as to the lines on which the existing Code of Regulations should be amended, as well as those in force in Germany, whilst photographs and diagrams are appended to show methods of applying exhaust draught, actually in use.—M. J. S.

Zinc Cement for Steam-Joints. A. Livache. Bull. Soc. d'Encour., 1905, 107, 568–570.

A CEMENT for steam-joints is described which is composed of "zinc-gray," a metallic powder obtained in the manufacture of zinc-white, made into a paste with wood oil. It contains no lead compounds, and is, consequently, harmless to handle; it does not harden on keeping, and hardens more quickly when exposed to heat than the ordinary red-lead mastic.—W. H. C.

UNITED STATES PATENTS.

White Lead; [Electrolytic] Process of Making —. C. P. Townsend. Washington. U.S. Pat. 791,956, June 6, 1905.

SEE FR. Pat. 349,001 of 1904; this J., 1905, 627.—T.F.B.

Dyestuff adapted to form Lakes; Azo —. P. Julius and E. Fussenecker, Assignors to Badische Anilin und Soda Fabrik. U.S. Pat. 792,421, June 13, 1905. IV., page 726.

Paint; Luminous —. H. Lieber, New York. Pat. 791,631, June 6, 1905.

THE composition contains a luminescent compound, radio-active excitant, and an adhesive and quick-drying substance; for example, a composition of zinc sulphate, radium-barium carbonate, and a quick-drying adhesive.—E. S.

Oil; [Paint —.] and Process of Making same. W. N. Blakeman, Jr., New York. U.S. Pat. 792,113, June 13, 1905.

A NON-DRYING fatty oil such as cottonseed oil is oxidised and then "claidinised" by treating it with an oxidising agent. After this treatment it is mixed with a drying oil, such as tung oil, with or without the addition of a non-drying fatty oil or an oil which has been only partially "claidinised."—A. S.

Paint, and Process of Making same. W. N. Blakeman, Jr., New York. U.S. Pat. 792,114, June 13, 1905.

THE paint is prepared by mixing an oxidised and "claidinised" non-drying fatty oil such as cottonseed oil (see preceding abstract) with a drying oil such as tung oil, with or without the addition of a non-drying fatty oil or an oil which has been only partially "claidinised" and then grinding an anhydrous pigment with the mixture.—A. S.

FRENCH PATENT.

Lakes: Process for Preparing —. Farbenfabr. F. Bayer und Co. Fr. Pat. 349,587, Dec. 21, 1904. Under Int. Conv., June 16, 1904.

RED lakes, fast to light, are obtained by precipitating a suitable substratum, in the usual manner, the dye produced by combining the diazo derivative of *o*-toluidine or *o*-anisidine with 1,5-naphtholsulphonic acid.—J. B.

GERMAN PATENTS.

White Lead: Process for the Manufacture of —. Z. Peska. Ger. Pat. 158,309, June 5, 1903.

LEAD oxide suspended in a solution of a suitable lead salt (acetate, nitrate, &c.), is subjected to the action of carbon dioxide or gases containing carbon dioxide. It is stated that the product obtained in this way is of a good white colour, and also, is amorphous, which is of importance, as crystalline white lead has not such a good covering power.—A. S.

Carbon Electrodes of Arc Lamps: Process for the Production of Waste — [Pigment]. R. Peters. Ger. Pat. 158,151, Jan. 19, 1904. Addition to Ger. Pat. 149,933, Feb. 14, 1903. (See Fr. Pat. 335,795 of 1903; this J., 1904, 260.)

THE waste carbons are heated to 1200°–1400° C. and then allowed to cool very slowly, whereby they become friable, and can be ground to a soot-like powder suitable for the preparation of paint. In the present patent the quenching in oil prescribed in the main patent (*loc. cit.*) is dispensed with.—A. S.

(B.)—RESINS, VARNISHES.

Shellac; Decomposition of — by Distillation. A. Etard and E. Wallée. Comptes rend., 1905, 40, 1603–1606.

SHELLAC was mixed with sand and distilled from an retort. There was obtained: about 22 per cent. of residue, almost free from ash, about 6 per cent. of gas and about 72 per cent. of distillate. The distillate consisted of an aqueous and an oily layer, the latter representing about 52 per cent. of the original oil, when dried. It contained very little basic matter, but about 40 per cent. of oil of similar character, and 60 per cent. of essential oil. The former consisted essentially of oleic acid, the latter mainly of various hydrocarbons of the terpene and polyterpene classes. The authors conclude that shellac consists essentially of a mixture of not very stable oleates of a continuous series of polyterpenes, and that such compounds are

of all industrial varnishes. They point out that resins seem to be constituted in an analogous way, consisting of bornyl acetate and similar terpene and esters of higher acids with polyterpenes. — E. F.

ENGLISH PATENT.

Fluid [Solvent for Resins] and Process of Making same. W. Oppenheimer and T. O. Kent. Eng. Pat. 4271, Feb. 20, 1904. III., page 722.

FRENCH PATENTS.

Products; Apparatus for Distilling—and Condensing the Distillation Products. H. Ropais. Fr. Pat. 349,543, Dec. 24, 1904.

The apparatus is characterised by the combination of a still with internal steam pipes communicating the ends with the jacket space, and a condensing element. The bottom of the still is inclined towards a l outlet for the distillation residue, with a draw-below by means of which the residue is removed. Heating steam is admitted to the jacket-space and passes through the tubes mentioned above. The dryness of the product during the distillation can be tested by means of a helical steam pipe passing down the centre of the still. The distillation process escapes through an outlet-pipe in the head of the still and passes to the condensing chamber, in which they are led to follow a zig-zag course by means of partitions or — A. S.

Substitute for Varnishing Furniture, &c.; Process of Preparing a —. C. Ludwig. Fr. Pat. 350,733, Dec. 13, 1905.

U.S. Pat. 760,541 of 1904; this J., 1904, 670.—T. F. B.

(C.)—INDIA-RUBBER. ETC.

from North-eastern Rhodesia; "Muteke" —. Bull. of the Imp. Inst., 1905, 3, 14—16.

SAMPLES of rubber, obtained from the branches of "muteke" or "mutecha" plant from North-eastern Rhodesia, was quite dry and free from stickiness; it had good tenacity and elasticity, and was completely soluble in benzene, carbon bisulphide, and chloroform, and slightly in ether. It had the following composition:—Moisture 4.6 per cent., resin 12.0 per cent., caoutchouc 79.7 per cent., dirt and insoluble matter 3.7 per cent. (including 0.4 per cent.). The percentage of caoutchouc in the material was thus 83.6. Its value was computed at 3s. 6d. per lb.—T. F. B.

from Rhodesia; "Dande" —. Bull. of the Imp. Inst., 1905, 3, 16—19.

SAMPLE of rubber, weighing 155 grms., was obtained from Jantah district of Rhodesia; it had been collected from the plant known as "Dande," which proved to be closely allied to *Landolphia petersiana*. The rubber had good physical properties, and showed the following composition:—Moisture, 15.5 per cent.; resin, 10.7 per cent.; caoutchouc, 68.1 per cent. (=80.7 per cent. dry material); dirt and insoluble, 5.7 per cent. (including ash, 1.6 per cent.). The sample was valued at 3s. 6d. per lb. in London.—T. F. B.

ENGLISH PATENT.

Fluid [Rubber Solvent] and Process for Obtaining same. W. Oppenheimer and T. O. Kent. Eng. Pat. 4271, Feb. 20, 1904. III., page 722.

FRENCH PATENT.

Caoutchouc and Gutta-Percha; Process and Apparatus for the Extraction of Vegetable Juices and Latexes, especially of those which yield —. C. E. Giovetti, R. Grundler and H. Haberer. Fr. Pat. 349,527, March 31, 1904.

The apparatus consists of two parts: (1) a shield which is fixed firmly to the tree against the incision: and (2) a

reservoir from which the air can be exhausted. The shield has a short, projecting tube which is connected to the reservoir. It is claimed that by means of this apparatus, better yields of latex are obtained with fewer incisions than by the ordinary method, and that no coagulation of the latex takes place, owing to the exclusion of air.—A. S.

XIV.—TANNING, LEATHER, GLUE, SIZE.

Mallet Bark; a New Australian Tanning Material. Bull. of the Imp. Inst., 1905, 3, 69—70.

MALLET bark, which is the name given to the bark of *Eucalyptus occidentalis*, has recently been imported into Europe from Queensland, 12l. 10s. to 13l. 10s. per ton being obtained for it. About 500 tons were used locally in 1903, and 4000 to 5000 tons were collected during 1904; this year's production is expected to be much greater. The bark is of medium thickness, and is cinnamon coloured, containing from 35—45 per cent., and occasionally up to 50 per cent., of a readily soluble tannin, which yields a firm, tough, light brown leather, free from the pink colour of leather tanned with wattle bark. At present it is chiefly used alone or in conjunction with valonia for medium weight leather.—T. F. B.

Maletto (Mallet) Bark. J. Paessler, D. Gerber Zeit., 1905, 48 [53—58]; Chem.-Zeit., 1905, 29, Rep. 171.

THE average composition of maletto bark (from *Eucalyptus occidentalis* Endl.) is: tanning substances 42 per cent. (35—52), non-tannin 7.0 per cent., insoluble matter 36.5 per cent., moisture 14.5 per cent. It forms a very cheap tanning material and can be easily extracted with water, for the most part without heat, the liquor having a density of 8—10 B. The use of steam under high pressure, on the other hand, causes decomposition of the tanning principles and deteriorated colour, the latter defect being imparted to the leather. The usual colour resembles that imparted by oak tan, but prolonged exposure to light turns it a decided reddish tinge, like mangrove tan. Owing to the small proportion of sugars (9 parts per 100 of tanning principles) the liquor does not become very acid. So far as can be ascertained, the bark is free from substances injurious to leather, but it should not be used in any large proportion when light shades are desired. The commercial extract has the density 22—24 B. and contains 30—36 per cent. of tanning substance.—C. S.

Pickling Process; Study of the —. W. Eitner and Stiazny. Der Gerber, 1905, 31, 125—127, 139—141, 155—156.

THE authors have made a systematic series of experiments with mixtures of salt and various acids for pickling skins preparatory to tanning. Experiments with hydrochloric, acetic and lactic acids showed that these offer no advantages over sulphuric acid for use in pickling; the pickled pelts and the leather produced from them being similar in appearance and quality. By varying the concentration of the pickle liquors, it was found (1) that the amount of salt absorbed by the pelt from the pickle liquor was controlled by the concentration of the solution; 23 to 25 per cent. of the total amount used being taken up by the pelt; (2) the absorption capacity of the pelt for acid was limited.

The goods pickled with the largest amount of acid possessed a more leathery feel and after drying were fuller and stretched much better than those in which smaller amounts of acid were employed. Dried pickled pieces, containing as much as 3 per cent. of sulphuric acid, showed no deterioration or tendering of fibre. The pickled skins after chrome tanning still retained these characteristics. An analysis of the leather produced by tanning with sumach showed that no free acid was retained in the finished leather. An Australian pickled pelt was found to contain 19.2 per cent. of salt and 2.8 per cent. of sulphuric acid.

From a very large number of experiments the authors draw the following conclusions:—

(1) That sulphuric acid is quite equal in efficiency to other acids for the purpose. (2) To a certain limit increasing softness is produced by increasing the quantity of acid used. (3) For naturally soft skins and when a leather not very soft is required the best results are obtained by using 10 kilos. of salt, 1 kilo. of sulphuric acid and 100 litres of water for 50 kilos. of pelt in the drum. (4) For material which is naturally hard and when a soft leather is required, the amount of acid should be increased to 2 kilos., using similar amounts as those given above of pelt, salt and water.—M. C. L.

ENGLISH PATENTS.

Leather, Tanning of Hides into — N. L. Tullis, Linlithgow, Scotland. Eng. Pat. 12,388, June 1, 1904.

THE hides after unhairing and fleshing are placed in a solution of ferrous salts in conjunction with alkali sulphites, bisulphites or thiosulphates; equal amounts of the ferrous salt and the alkali salt being generally used. The tannage with the iron salts may be preceded by a preliminary tannage with alum, chrome or formaldehyde.—M.C.L.

Bating, De-Acidifying and Oxidising Hides and Skins. O. P. Amend, New York. Eng. Pat. 18,514A, Aug. 26, 1904.

UNITED STATES PATENT.

Fertiliser, and Process of Making same. W. B. Chisolm, Charleston, S.C. U.S. Pat. 792,314, June 13, 1905.

SULPHUR and lime are boiled together, to produce a homogeneous liquid, and this solution of calcium sulphides is mixed and thickened with phosphate, and the mass is then ground, to constitute a fertiliser.—E. S.

FRENCH PATENT.

Sewage and other Refuse; Treatment of — J. L. F. Garrigou. Second Addition, dated Dec. 22, 1904 and Fr. Pat. 340,740, Feb. 26, 1904. XVIII.B., page 747.

GERMAN PATENT.

Fertiliser; Process for the Manufacture of a — from Shells. Kölner Ceresinfabrik Gebrüder Maus, G. m. b. H. Ger. Pat. 157,276, Dec. 21, 1902.

THE shells are treated with acetic acid and the solution separated. The residue contains nitrogenous substances and calcium phosphate and forms a useful fertiliser, whilst from the solution, glue and calcium acetate are obtained as by-products.—A. S.

XVI.—SUGAR, STARCH, GUM, Etc.

Sucrose in presence of Levulose and Dextrose; Determination of — H. Pellet. Bull. Assoc. Chim. Sucr. Dist., 1905, 22, 1041–1048.

THE rotatory power of pure levulose in aqueous solution is increased by the action of strong acids, but not by

acetic or sulphurous acid, and only slightly by sulphuric. Exposure to prolonged heat (105° to 107° C.) produces notable diminution in the rotation of levulose, whether pure or in presence of salts, and the rotation is now longer modified by the addition of strong acids. It is therefore useless to acidify the liquids obtained from sugar works for polarisation before the Clerget invers. In cane molasses, the rotatory power of levulose is variable according to the conditions under which the juice of the products obtained from it, have been heated. The more these products have been subjected to a high temperature, and the more will the levulose have suffered diminution of its rotatory power. The rotatory power of levulose being thus variable and unknown, it is not possible to calculate the proportions of levulose and dextrose in cane molasses with certainty. This is probably an explanation of the very variable results obtained by different observers with cane molasses.—L. J. DE W.

Starch; coagulated by Amylocoagulase, Analogy between and the Natural Starch of Peas. A. Fernbach and Wolf. Comptes rend., 1905, 140, 1547–1549.

THE starch separated from green peas differs from other natural starches in containing a high percentage of amylose, cellulose unsaccharifiable by malt. In fact, there is a very close analogy between pea starch in its natural condition and potato starch which has been coagulated by amylocoagulase. When pea starch is boiled with a relatively small proportion of water, it forms an opaque jelly on cooling; when boiled with a larger quantity of water, it gives a solution which can be filtered clear while hot. The filtrate deposits, on cooling, a pulverulent or gelatinous precipitate (amylocellulose), unsaccharifiable by malt, but if the hot filtrate be received directly in alcohol extract, its saccharification is complete. The insoluble residue has the appearance of the skeletons of the granules; it gives a blue coloration with iodine; after saccharification the residue is morphologically unchanged, but the iodine reaction is reddish-brown. Pea starch yields 82.43 per cent. of starch soluble in boiling water, and completely saccharifiable. The residue, amounting to 17–18 per cent., is amylocellulose, soluble in water only on heating at 150° C. When the starch is boiled with water and allowed to cool completely, the unsaccharifiable residue is increased to about 22 per cent., the extra 4 per cent. of amylocellulose having been formed during cooling.—J. F. B.

ENGLISH PATENTS

Sugar [Leuculose]; Manufacture of — S. Stein and M. Loewenthal, both of Liverpool. Eng. Pat. 16,606, July 27, 1904.

LEVULOSE is prepared by pulping dahlia bulbs or chicory roots with water, heating, defecating and clarifying the liquid by means of suitable reagents, and saccharifying the extract either by means of its own acidity or by acid added. The solution of levulose is then purified and concentrated to a thick syrup or solid mass.—J. F. B.

Inulin; Manufacture of — S. Stein and M. Loewenthal, both of Liverpool. Eng. Pat. 16546A, July 7, 1904.

THE bulbs or roots of dahlia or chicory are ground to a pulp, with or without the addition of water. Magnesia is then added to the pulp in order to neutralise the acidity and facilitate the filtration. After filtration in the wet state, the liquid is defecated by the addition of tan, aluminium salts or other suitable precipitating agents and again filtered. The inulin is deposited from the filtrate by cooling, the deposition being accelerated by freezing and subsequently thawing the solution.—J. F. B.

FRENCH PATENTS.

cautes and Granulated Sugar; Continuous Apparatus for Cleansing —. A. Landrin and M. Moullier. Pat. 349,418, March 24, 1904.

massecuite is fed upon an endless band of wire gauze carries it over a series of separate suction boxes, in which the layer of massecuite is subjected simultaneously to the pressure of the cleansing syrups sprayed above and to the action of an exhaustor sucking below. The thickness of the layer of massecuite is regulated by a valve at the feed-discharge, and the suction in each box can be regulated independently.—J. F. B.

Massecuites; Vertical Mixing Device for —. Anon. de Constructions Mechaniques de St. Quentin. Pat. 349,803, Dec. 31, 1904.

mixer, especially suitable for crystallising vessels in refineries, possesses a set of agitating arms fixed to a vertical rotary hollow shaft, inside which is a rotary screw which raises the mass from the bottom of the vessel and distributes it by means of a channel over the whole length of the massecuite as the shaft rotates.—J. F. B.

GERMAN PATENTS.

for [Beet] Slices with a Continuous Screw on a Cylindrical Spindle. A. Eitner. Ger. Pat. 157,907, June 13, 1903.

spindle of the press is preferably constructed in two parts, of which the upper one carries the pressing-screw which rotates, whilst the lower one carries a conical casing or mantle, which does not rotate, and is provided with openings through which the expressed water passes into the hollow spindle. The spindle carrying the screw is disposed inside an outer chamber, so that the space between the conical casing and the walls of the chamber becomes narrower as it approaches the outlet for the pressed material. It is claimed that by this press, the loss of juice is caused owing to reduction of the beet-slices to a fine pulp as is the case in the usual presses in which the spindle is a number of wings or blades arranged in the form of a spiral, and with screens interposed between them.—A. S.

for [Beet] Slices. A. W. Mackensen. Ger. Pat. 158,614, July 11, 1903.

object of the invention is to prevent the loosening of the compressed material in the interval between the blades of successive press-blades. For this purpose, the individual or nearly horizontal covering-blades are provided with side-blades, which cover the spaces between the individual press-blades. These covering blades may be connected to the press-blades or to the spindle of the press.—A. S.

Centrifugal Machines for Syrups and other Liquids; Device for Collecting Separately the Discharge-Liquors —. A. Fesca und Co. Ger. Pat. 158,275, May 14, 1903.

the drum of the centrifugal machine is arranged with an annular collecting channel consisting of a series of funnel-shaped vessels or pockets, each with an outlet at the bottom. Below this collecting channel are arranged a series of distributing channels disposed in sets, the corresponding channels in each set communicating with a common discharge-channel. When the centrifugal machine is rotated, the outlets of the funnel-shaped vessels are immediately above the distributing-channels communicating with one of the discharge-channels, whilst by

rotating the collecting channel, the distributing channels are connected with any other discharge channel, and the liquor is brought at will, under the outlets. A. S.

XVII.—BREWING, WINES, SPIRITS, Etc.

Fermenting Liquids; Influence of Metals on —. H. L. Nathan. Centralbl. Bakt., 1905, 14, 289; Chem.-Zeit., 1905, 29, Rep. 154.

In continuation of his previous studies (this J., 1904, 876), the author placed cylinders of various metals and alloys in fermenting fruit musts and beer worts. The course of the fermentation was more profoundly affected by the metals in the case of the fruit musts, but in the case of the beer worts the alterations in the organic composition of the liquid were the more serious, since the slightest quantity of dissolved metal caused the destruction of the beer by albuminoid turbidities. The conclusion is drawn that the fermentation of fruit musts should be carried out only in glass, glazed, enamelled or nickel-plated vessels with fittings of aluminium, whilst the same recommendation applies for beer with the exception that aluminium is to be avoided, and the fittings should be made of copper. All metallic surfaces should be highly polished so as to reduce the danger of attack.—J. F. B.

Disinfectants in the Brewery; Comparative Investigations on Certain —. H. Will. Z. ges. Brauw., 1905, 28, 330—333, 347—349. (See this J., 1904, 125.)

According to their relative germ-destroying powers, the author arranges the various antiseptics available for brewery use in the following order from the weakest to the strongest:—Antinonin, microsol, montanin, antigermin, ammonium fluoride, formalin, hydrofluoric acid, antiformin.

Arranged according to their relative powers of preventing the development of micro-organisms, the order from the weakest to the strongest is:—Antiformin, ammonium fluoride, montanin, antinonin, microsol, antigermin, hydrofluoric acid, formalin.

Formalin therefore takes a very high place amongst the brewery antiseptics; it is more powerful against bacteria (e.g., *sarcina* and acetifying organisms) than against yeasts and mould fungi. The following limiting concentrations of formaldehyde are recorded as preventing development:—*Sarcina* and bacteria, 0.003—0.031 per cent.; yeasts, 0.007—0.062 per cent.; mould fungi, 0.031—0.125 per cent.

For the destruction of micro-organisms by fumigation, formalin gave somewhat disappointing results.—J. F. B.

Acetyl-methylcarbinol; Presence [and Determination] of — in Certain Commercial Vinegars. Pastureau. J. Pharm. Chim., 1905, 21, 593—595.

Detection of Acetyl-methylcarbinol.—On adding 95 per cent. alcohol to the vinegars, a more or less copious precipitate was formed, and they were also found to exert a powerful reducing action on alkaline cupric tartrate, in the cold. On neutralising and distilling, the distillate, which was free from furfural, gave a copious precipitate of iodoform when treated with iodine; it had a powerful reducing action on alkaline cupric tartrate, and gave with phenylhydrazine a lemon-yellow crystalline osazone, m. pt. 243° C. The ether-alcohol solution of this osazone afforded, with ferric chloride, a characteristic blood-red colour, and, on evaporation of the solvent, red needles of the corresponding osotetrazone. The reducing body was thus identified as acetyl-methylcarbinol or methylacetol $\text{CH}_3\text{CO}\cdot\text{CH}(\text{OH})\cdot\text{CH}_3$.

Determination of Acetyl-methylcarbinol.—Fifty c.c. of the vinegar, neutralised with sodium carbonate, were distilled to dryness, avoiding overheating. The distillate was rendered alkaline with sodium carbonate and ammonia, and treated with 10 c.c. of N/10 silver nitrate solution. After standing for 24 hours, the liquid was made up to 100 c.c., filtered, and the unreacted silver nitrate remaining in the liquid determined by the eyanometric method. Each molecular equivalent of reduced silver is equivalent

to three molecules of methylacetol, according to the equation:—

In the vinegar examined the amount of methylacetol present was equivalent to 3.256 grms. per litre.—J. O. B.

Starch Coagulated by Amylocoagulase. Analogy Between —, and the Natural Starch of Peas. A. Fernbach and J. Wolff. XVI., page 744

ENGLISH PATENTS.

Hops, Malt, &c.: Sulphuring —, so as to Avoid Contamination with Arsenic. J. L. Baker and A. R. Ling. Eng. Pat. 16,992, Aug. 3, 1904.

WHEN sulphur is thrown upon fuel for sulphuring hops, malt, &c., any arsenic in the fuel, which might otherwise be fixed by the mineral matter of the latter, is rendered volatile. The kiln is therefore so arranged that the sulphur dioxide is generated separately from the kilning furnace, in a special stove provided with a chamber into which the sulphur is introduced upon a tray, dampers being arranged in front for the admission of air and an outlet pipe at the back for the escape of the gas into the kilning chamber, where it mixes with the heated air from the furnace.—J. F. B.

Beers and Stouts for Bottling; Production of Non-deposit —. W. G. Storrier, Alloa. Eng. Pat. 12,417, June 1, 1904

THE apparatus for cooling and carbonating beer previous to filtration and bottling, consists of a horizontal cylindrical vessel fitted with a central rotary shaft. The end portions of this shaft are hollow and perforated, and act as inlet and outlet respectively for a cooling liquid. Inside the vessel the shaft is surrounded by a cylindrical jacket through which the cooling liquid circulates. The space between the cooling cylinder and the walls of the container is filled with the beer to be treated, the beer being kept in motion by stirring paddles attached to the rotary cooling cylinder.—J. F. B.

FRENCH PATENTS.

Barley and Other Malting Grains: [Electrical] Process for Steeping and Germinating —. Deichmann and Co. Fr. Pat. 349,478, Dec. 12, 1904.

THE grain is exposed, during the operations of steeping and germination, to the undulatory motion of high-tension currents, at a tension exceeding 1000 volts, but not attaining the tension of Tesla currents. The undulatory motion is defined as the effect of radiations transmitted by the agency of the air. This electrical treatment is stated to increase the percentage of extract and mellow corns and to decrease the percentage of protein of the malt, at the same time increasing the yield of malt dry substance obtained.—J. F. B.

Yeast from Dates: Manufacture of —. L. van den Hoff. Fr. Pat. 349,844, Nov. 10, 1904.

A YEAST possessing special properties, very resistant to high temperatures, is prepared from the fruits of the date palm (*Phoenix dactylifera*). A must is prepared by steeping the dates, expressing the juice, and defecating the latter at a temperature of 105° C. This must is fermented at a temperature of 25° C. by a special yeast isolated by selection from the date fruits themselves. Fermentation lasts for six days, the temperature being reduced at the rate of 2° C. per day. The fermented juice is heated to 65° C. for three hours, cooled, bottled and pasteurised at 70° C. This liquor serves as a medium for the revivification of cultures of the special yeast isolated from the dates, which cultures are preserved in tubes in a thick sugar syrup.—J. F. B.

XVIII.—FOODS; SANITATION; WATER PURIFICATION, & DISINFECTANTS.

(A).—FOODS.

Butter: The Proteids of Cream, Butter and Butter in Relation to "Mottled" —. L. L. van Slyke and E. B. Hart. J. Amer. Chem. Soc., 1903, 27, 679.

WHEN the amount of lactic acid in cream exceeds 0.1 per cent., neither calcium casein nor free casein is present but only casein lactate, the butter and butter-milk the cream also containing only casein lactate. In butter and butter-milk made from "sweet" cream, calcium casein and some free casein are found.

The light spots or streaks in butter, known as "mottles" are due, first, to the presence and uneven distribution of butter-milk adhering to the outer surface of the granules; and, secondly, to the hardening and local effect of brine upon the proteid thus retained in the butter. The light portions of mottled butter are, therefore, caused by the presence of a proteid, usually casein lactate, while the yellow or clear portions occur where the spaces between the butter granules are filled with clear brine, and contain comparatively little proteid. Several hours are required to complete the hardening action of the brine on the proteid.

Mottles in butter can be prevented by washing butter granules twice with water at a temperature of 35° to 45° F., to remove the butter-milk before salting. The churning should be so managed that the butter granules are about the size of rice grains. (For nomenclature of casein compounds see this J., 1905, 27, 100.) —W. P.

Starch coagulated by Amylocoagulase; Analogy between — and the Natural Starch of Peas. A. Fernbach and J. Wolff. XVI., page 744.

Milk: Detection of Formalin in —. Utz. XXIII., page 752.

Alimentary Substances; Apparatus for Eliminating Moisture from —. A. Witschi-Studer, Hindelk. Switzerland. Eng. Pat. 11,466, May 18, 1904. U.S. Int. Conv., May 19, 1903.

IN a chamber or oven—heated by suitable means—are arranged a number of trays, one above the other. The front and back of the oven are closed by doors made up of pivoted plates which can be opened or closed at will to any extent. The bottom of each tray, except the lowermost one, is made of over-lapping pivoted plates, which can be opened so that the contents of the tray fall into the next lower tray. The material, such as meal, &c., is placed in the upper tray. After partial drying, it is allowed to fall to the next tray, and so on, the perfectly dry material being withdrawn from the bottom tray. As the dried material is withdrawn, fresh material is placed in the top tray. The trays are moved on rollers running on ledges fixed to the sides of the chamber, to facilitate moving them in and out of the latter. For drying fruit, &c., the bottoms of the trays may be formed of fine or coarse wire-netting.—W. P. S.

Alimentary Product [Dried Yolk of Egg]; Manufacture of an —. J. Poumay, Brussels. Eng. Pat. 68, March 24, 1905.

YOLKS of eggs separated from the whites are thoroughly mixed with one-third of their weight of water. The resulting emulsion is strained and evaporated under reduced pressure at a temperature of 40°–50° C. to a paste. The latter is further dried over quick-lime or the like at a temperature of 25°–30° C. and ground to a fine powder.—W. P. S.

Centrifugal [Milk] Separators; Feeding Arrangement for —. S. C. Hanberg, Copenhagen. Eng. Pat. 19,565, Sept. 10, 1904.

To cause the milk entering the drum to impinge on

readily separated "cream column" instead of directly at the edges of the skimming plates, the apertures in the central feed pipe are arranged at or near the middle of the interstices between the projecting edges of the tube, and within the inner contour of the "cream column."—C. S.

UNITED STATES PATENT.

Cream, &c.; Process of Treating — [Condensing]. R. Kennedy, Assignor to the American Dairy Products and Manufacturing Co., Philadelphia, Pa. U.S. Pat. 791,270, May 30, 1905.

Milk, cream, or mixtures thereof, are evaporated and dried until a large portion of the lactose and salts crystallize out. The latter are filtered off, and the resulting residue further concentrated by evaporation. (See also Pat. 787,044, 1905; this J., 1905, 510.)—W. P. S.

3).—SANITATION; WATER PURIFICATION.

ENGLISH PATENTS.

Sege; Filter and Contact-Beds for the Bacterial Treatment of — R. Middleton, Leeds. Eng. Pat. 15,829, July 16, 1904.

Filter-beds are built up from special forms of glazed rough earthenware, either piled up geometrically or irregularly thrown together on the bed. The forms of earthenware particularly described are oblate spheroids, spheres, and double pyramids. Where these are built up symmetrically, some of the smaller forms may be regularly interlarded, thus forming holes for flushing purposes, which may be kept open by the insertion of wooden rods. The size may be of different sizes and shapes in the same bed.—W. P. S.

Clarification. E. Vial, Brussels. Eng. Pat. 14,336, June 14, 1904.

Fr. Pat. 344,174 of 1904; this J., 1904, 1100.—T. F. B.

Apparatus for Purifying or Softening — G. Guttman, London. Eng. Pat. 5200, March 13, 1905.

An inner tank, acting as a storage vessel, is surrounded by an outer one, the latter being divided by diaphragms into compartments, one serving as a mixing tank for the reagents and chemical reagents, and the second as a filtering apparatus. The filtering compartment is again subdivided by diaphragms, and the various compartments communicate with each other on the same level. The filtering tanks, superimposed baskets of iron or wirework are placed, and the loose filtering material is packed in such a way that it protrudes through the wide meshes of the baskets. The material thus forms porous spaces between adjacent baskets and between the baskets and the sides of the tank, and prevents the water from passing through the apparatus without passing through the filtering material.—B. N.

FRENCH PATENTS.

Gases or Vapours produced in Certain Industries; Recovery of — by Refrigeration. J. B. A. Aurenque. Fr. Pat. 349,843, Nov. 4, 1904.

In the case of vapours which are heavier than air, openings are arranged in the floor of the workshop where they are produced. The vapours pass through and are conducted into conduits placed beneath to suitable apparatus where they are cooled and condensed.—W. H. C.

Wage; Purification of — M. M. Neilson. Fr. Pat. 349,467, Nov. 22, 1904.

The sewage is led into a closed ventilated tank, where it is acted on by aerobic bacteria, cultures of the latter being added to hasten the action. The liquid is then pumped into a tank where it passes upwards through a filter. Air is provided at the bottom of the tanks for removing solid mineral matters.—W. P. S.

Sewage and other Refuse; Treatment of — L. F. Garrigou. Second Addition, dated 11th Dec. 1904 to Fr. Pat. 340,740, Feb. 26, 1904 (this J., 1904, 843 and 1109).

The sewage is separated into two portions, liquid and solid—as described in the original patent. The liquid portion is then heated after the addition of lime or dolomite, the ammonia evolved being collected. The liquid is now sterilised by heat, allowed to settle, and passed through a filter-press when cold. The chalky precipitate obtained may be used as a manure, and the filtrate for irrigation purposes, &c. Powdered charcoal may be added to the filtrate in case the latter is not completely de-odorised when it leaves the filter-press. The more solid portion of the sewage is mixed with "plaster" and powdered charcoal in sufficient quantity to form a hard cake on drying at a temperature below 120° C. under pressure. Before drying, phosphates, ammonium salts, brewery wastes and the like, may be added, to increase the manurial value of the cakes.

—W. P. S.

GERMAN PATENTS.

Fatty Acids; Process for the Recovery of Fat from Sewage, Effluents and the like, in the Form of — F. Kaepfel. Ger. Pat. 159,170, Jan. 20, 1903. XII., page 741.

Water; Apparatus for the Softening of — L. Hwass and F. Heimberg. Ger. Pat. 159,378, Aug. 26, 1903.

The water is treated with alkalis or lime, and then flows into a chamber, wherein it is treated with an acid, e.g., oxalic acid, for the neutralisation of the last traces of lime or alkali. The water after the treatment with lime flows down through a pipe, enlarged at its lower end in the form of an inverted funnel and then rises in the chamber surrounding the pipe, the calcium carbonate being deposited on the bottom of the chamber. The addition of oxalic acid is made in a chamber made in the form of an inverted cone, which surrounds the water-inlet pipe above the funnel-shaped portion.—A. S.

(C).—DISINFECTANTS.

Disinfectants in the Brewery; Comparative Investigations on Certain. H. Will. XVII., page 745.

UNITED STATES PATENT.

Fumigation [Disinfecting]; Process and Compound for — H. V. Walker, Brooklyn. U.S. Pats. 790,468 and 790,469, May 23, 1905.

The process consists in adding to a solution of some gaseous disinfectant, such as formaldehyde, aluminium sulphate and a substance which will unite with water, e.g., quicklime. The "compound" claimed in the second patent is an aqueous solution of formaldehyde containing aluminium sulphate; lime is added to this in sufficient quantity to absorb all the water, thus liberating formaldehyde.—T. F. B.

GERMAN PATENTS.

Iodophenol-formaldehyde Compounds [Disinfectants]; Method of Preparing — F. Henschke. Ger. Pat. 157,554, Oct. 6, 1903.

A compound of iodophenol with formaldehyde, possessing antiseptic properties, is obtained by the action of iodine in alkaline solution on the product of condensation of phenol and formaldehyde (see Fr. Pat. 345,398 of 1904; this J., 1904, 1233).—T. F. B.

Mercury Preparations [Disinfectants] which will not Attack Metals; Process for Preparing Easily Soluble — M. Emmel. Ger. Pat. 157,663, Oct. 31, 1903. Addition to Ger. Pat. 121,656, Nov. 22, 1898.

Preparations of mercury, of use as disinfectant coatings, and which do not attack metals, are obtained by adding to the mercury salt (e.g., the cyanide, "oxycyanide,"

or *p*-phenolsulphonate) an alkali oxide or hydroxide, instead of an alkali carbonate or bicarbonate as in the principal patent.—T. F. B.

XIX.—PAPER, PASTEBOARD, Etc.

Straw Cellulose: Manufacture of — by the Sulphite Process. L. Gottstein. Z. angew. Chem. 1905, 18, 983—984.

REFERRING to the article by Dietz on the above subject (this J., 1905, 557), the author states that in 1885 he prepared large quantities of straw cellulose by the sulphite process in Sweden, in the same boilers as were employed for wood pulp. These boilers were of the rotary type, 30—40 cm. in capacity, lined with lead plates. Whereas with the soda process it is necessary to remove the knots of the straw before boiling, this was not so with the sulphite process, since the knots were so slightly attacked that they were easily separated when the pulp was strained. The straw cellulose thus prepared, bleached to a good white, and was employed without comment by the manufacturers of writing papers. The preliminary extraction of the silica by hydrofluoric acid, as recommended by Dietz, was not practised. In the author's opinion the necessity for such an extraction has not been fully demonstrated, but it may possibly prove to be a technical advantage.—J. F. B.

Lignocelluloses: Methoxyl Determinations in Certain —. A. S. Wheeler. Ber. 1905, 38, 2168—2169.

THE results of the determination of the methoxyl group in the woods of certain trees, occurring in the Southern States of North America and the West Indies, are recorded:—

Botanical Name.	Local Name.	Methyl (as CH ₃)
		Per cent.
<i>Diospyros Virginiana</i> , L.	Persimmon	1.95
<i>Magnolia tripetala</i> , L.	Umbrella tree	2.57

—J. F. B.

Acetylcellulose. C. Haenssermann. Chem.-Zeit., 1905, 29, 667.

ACETYLHYDROCELLULOSE was dissolved in 15 times its weight of fuming nitric acid, and the solution was allowed to remain for 14 days, at the end of which time it had become clear and less viscous. On pouring into water, a product was obtained which dried to a fine white powder soluble in acetone, ethyl acetate and amyl acetate. This product is regarded as a nitrate of hydrocellulose, derived from the acetate by the displacement of the acetyl groups and their partial substitution by nitric acid. The substance was explosive, and contained 11.5 per cent. of nitrogen. On denitration by sodium hydrosulphide the corresponding hydrocellulose was obtained as a white powder, completely soluble in cold 10 per cent. caustic soda and capable of reducing Fehling's solution.—J. F. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

Aldehydes: Synthesis of — by means of Formic Acid. J. Houben. Chem.-Zeit., 1905, 29, 667—668.

MAGNESIUM-ALKYL chlorides react with formic acid in ethereal solution, with the production of aldehydes. The author's experiments relate to the synthesis of phenyl aldehyde by the action of benzylmagnesium chloride and formic acid. Copper formate may be employed in place of formic acid. The yields are only small, to wit: dibenzyl and dibenzylcarbinol having been identified amongst the by-products of the reaction.

In a similar manner *n*-propylmagnesium chloride reacts with butyric aldehyde on treatment with formic acid. Low yields are ascribed to the unsuitability of ether as a solvent medium.—J. F. B.

Alkaloids of certain Mydriatic Solanaceous Plants. Schmidt. Arch. Pharm., 1905, 243, 303—309.

Datura metel.—Further experiments with the alkaloids cultivated at Cassel, confirm the author's previous statement that scopolamine is the only base produced. He also found that this is the case with the entire plant, all the organs examined having yielded scopolamine. In this important respect, *Datura metel* differs from *D. alba*, the flowers of which have been shown by Browne and by others to yield scopolamine, whereas the leaves and seeds, according to Shimoyama and Koshima, contain hyoscyamine and a little atropine. Hitherto the only available commercial source of scopolamine (the hyoscyamine of O. H. Sars) has been the root of *Scopolia*, where it is accompanied by much hyoscyamine. Small quantities only of scopolamine have been isolated from *Hyoscyamus* seeds; other Solanaceous plants have been stated to contain scopolamine as to be worthless as a practical source of the alkaloid. The dried leaves of *Datura metel* gave 0.55 per cent. of the seeds 0.5 per cent. of the base, which was proved to be pure *levo*-scopolamine, and to be identical with *levo*-hyoscyamine.

Since certain commercial specimens of scopolamine (hyoscyamine) hydrobromide, obtained from the *Scopolia* base, consisting of a mixture of *levo*- and *dextro*-scopolamine, have been found to give rise to unexpected secondary reactions, probably due to some undetected impurity, it is suggested that only *levo*-scopolamine of the purity of which could be determined by its optical rotation, should be employed for medicinal purposes.

Datura arborea yielded, in all parts, scopolamine accompanied by hyoscyamine.

Datura quercifolia gave from the leaves, 0.4 per cent. and from the seeds, 0.28 per cent. of total alkaloids. In quality, the mydriatic bases stand between those of *D. metel* and *D. stramonium*, consisting of about equal parts of scopolamine and hyoscyamine.

Datura stramonium yielded only hyoscyamine and no scopolamine.

Atropa belladonna.—The author has examined its fruit from wild plants, and has been able to isolate hyoscyamine from both ripe and unripe fruits, and further examination of all parts of the plant he finds hyoscyamine is the only mydriatic alkaloid present.—J. O.

me: Action of Methyl Iodide on — C. Mouren & A. Valeur. *Comptes rend.* 1905, **140**, 1691—1693.

Previous communication (this J., 1903, 961, 1305, 1365), others showed that sparteine was a tertiary base, $C_{15}H_{26}N_2$, saturated in character, not methyl- in either amino-group, and identical with the "ro-sparteine" formerly described. They now find on boiling sparteine with excess of methyl iodide in alcoholic solution, a mixture of two iodomethyl- sparteine is obtained. One of these, α , is relatively soluble in water, has rotatory power $[\alpha]_D = -22.75^\circ$, as already been described. The other, α' , is much less soluble in water, has not been obtained in quite a state, but has a much higher rotatory power, r than -36.9° . Both have the empirical formula $C_{15}H_{24}N_2I$. The authors consider them to be stereoisomers. — E. F.

nes and Essential Oils, 72nd Communication. β -phellandrene. O. Wallach. *Annalen*, 1905, **340**, 1—16. (this J., 1904, 997.)

Heating the hydrocarbon, β -phellandrene, with nitrous in a petroleum spirit, only a small yield of the nitrite is obtained, some of the hydrocarbon remaining unchanged. A portion of the nitrite formed at first, is converted into β -phellandrene and other products. The nitrite in a chloroform solution has $[\alpha]_D = -156.8^\circ$. If the nitro- compound (nitro- β -phellandrene) is reduced with zinc and acetic acid, dihydrocuminic aldehyde, $C_{10}H_{14}O$, is obtained, boiling at 111° — 112° C. at 13 mm. On oxidation with hypobromite, this passes into cuminic acid. If the β -phellandrene nitrite is reduced with sodium in alcohol, alcohol is produced. Amongst the basic products of reduction of the nitro-compound, are a hydro- xylamine, and cuminyamine. The author proposes a structural formula for β -phellandrene, and its nitrite nitro-compound. If β -phellandrene is cautiously oxidized with permanganate, a liquid glycol is produced, boiling at 150° under 10 mm. pressure. On steam-distilling dilute sulphuric acid, it is converted into tetrahydro- cuminic aldehyde, $C_{10}H_{16}O$. This boils between 220° — 230° C.; sp. gr., 0.93; n_D , 1.4903 at 20° . The semi- zone (m. pt. 204° — 205°) and oxime (m. pt. 87°) were obtained. On oxidation with silver oxide, tetrahydro- cuminic acid, $C_{10}H_{16}O_2$, m. pt. 143° — 144° C., is produced. The aldehyde is identical with the "phellandral" described by Schimmel and Co., occurring in the oil of *Andrium aquaticum*. (See this J., 1904, 1236.) — F. S.

Eucalyptus Oils of New South Wales containing the Pepper- mint Ketone. Bull. of the Imp. Inst., 1905, **3**, 4—6.

The following descriptions are given of eucalyptus oils of New South Wales containing the "peppermint ketone." The leaves of *E. piperita* yielded 0.627 per cent. oil, containing phellandrene, pinene, eucalyptol and peppermint constituent. Nearly 3.4 per cent. of oil obtained from *E. amygdalina*, containing phellandrene, eucalyptol, and the peppermint ketone as chief constituents. The oil from *E. vitrea* (1.48 per cent.) contains a large amount of phellandrene, some eucalyptol, the peppermint constituent and (probably) citral. The oils from *E. limniana* and *E. coriacea*, consist principally of phellandrene, and the yields average 0.29 per cent., and 0.10 per cent. respectively. *E. Siberiana* yields an oil containing much phellandrene and a fairly large amount of peppermint ketone, but no eucalyptol nor eudesmol. 1 per cent. of colourless oil was obtained from *E. oreades*, consisting largely of phellandrene. *E. dives* yielded 0.5 per cent. of oil consisting largely of phellandrene, and possessing an odour of peppermint; eucalyptol appeared to be absent. The oil from *Radiata* is similar to the last; the yield averaged 1 per cent. *E. delegatensis* yielded 1.76 per cent. of oil consisting principally of phellandrene. The oil from *E. obliqua*, which is yellowish in tint, contains phellandrene as its chief constituent, but differs from the oil from *E. dives*, &c., in having apparently aromadendral place of the peppermint constituent. — T. F. B.

Chousia Citriodora; Composition and Uses of the Volatile Oil of — from Queensland. Bull. of the Imp. Inst., 1905, **3**, 11—13.

The sample of the oil of *Chousia citriodora* had been distilled in Queensland from the native plant, consisted of a greenish-yellow, optically inactive liquid of sp. gr. 0.8903 at 21° C., and refractive index of 1.4344 at 22° C. On distillation, 100 c.c. yielded 10 c.c. containing 1 c.c. of water) boiling between 212° and 219° C., and 80 c.c. (consisting principally of citral) boiling between 219° and 231° C. The amount of citral in the oil as determined by the bisulphite process, was 93.5 per cent. The oil is similar to lemon-grass oil, and is valued at 7d. to 9d. per oz. in London. — T. F. B.

ENGLISH PATENTS.

Barbituric Acids and Intermediate Products; Manufacture of — F. Boehm, London. From E. Merck, Darmstadt, Germany. Eng. Pat. 14,014, June 21, 1904.

SEE FR. Pat. 344,980 of 1904; this J., 1904, 1237. — T. F. B.

Diethylmalonylurea [Diethylbarbituric Acid]; Method of Preparing — F. Mayer, Mainz, Germany. Eng. Pat. 2787, Feb. 10, 1905. Under Int. Conv., June 17, 1904.

DIETHYLMALONYLUREA (diethylbarbituric acid) is obtained by heating together, at about 100° C., equimolecular proportions of biuret and diethylmalonyl chloride; an amide of a carboxylic acid of diethylmalonylurea appears to be formed as an intermediate product. — T. F. B.

UNITED STATES PATENTS.

Dialkylbarbituric Acid; Process of Making — M. Engelmann, Elberfeld, Germany, Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 789,902, May 16, 1905.

NEUTRAL carbonic esters are condensed with dialkylmalonic acid diamides by means of alkaline condensing agents (e.g., alkali alcoholates). 5-dialkyl-2,4,6-trioxy pyrimidines being produced. Thus the 5-diethyl compound may be obtained by condensing diethyl carbonate with diethylmalonic acid diamide in presence of sodium ethylate. — T. F. B.

Diethylbarbituric Acids; Process of Making — A. Einhorn, Munich, Assignor to Farbwerke vorm. Meister, Lucius und Brünig, Höchst on the Main, Germany. U.S. Pat. 790,116, May 16, 1905.

DIALKYLTHIOBARBITURIC acids are converted into dialkylbarbituric acids by heating with mineral acids (e.g., by boiling with 33 per cent. sulphuric acid for a considerable time). — T. F. B.

C-C-Dialkylbarbituric Acids; Process of Making — E. Preiswerk, Assignor to Soc. Chem. Industry in Basle, Basle, Switzerland. U.S. Pat. 790,263, May 16, 1905.

On condensing the alkyl esters of carbonic acid with dialkylmalonic acid diamides in presence of sodium ethylate, C-C-dialkylbarbituric acids (pyrimidines) are obtained (see also U.S. Pat. 789,902, preceding). — T. F. B.

Nicotine; Process of Obtaining — A. Koelliker, Benel, Germany. U.S. Pat. 790,138, May 16, 1905.

NICOTINE may be obtained from "tobacco extracts

containing sulphuric acid" by neutralising with sodium hydroxide, distilling, adding sulphuric acid to the distillate, evaporating it until crystallisation commences, and then adding sodium hydroxide until the solution is just alkaline. —T. F. B.

FRENCH PATENTS.

Aldehydes R_1CH_2CHO and RR_1CH_2CHO ; Process for Preparing —. A. Belhel and M. Sommelet. Addition dated April 9, 1904, to Fr. Pat. 347,399, Jan. 6, 1904.

By condensing acid amides or nitriles with halogenated ethers of the general formula XCH_2OR (where X represents a halogen atom) in presence of magnesium (or zinc) and a zinc-copper couple, ethers of hydroxyketones are obtainable; on reduction, these compounds are converted into monoalkyl ethers of substituted glycols, *viz.*, $R_1CH_2OH.CH_2OR$. These latter compounds may also be produced by the direct condensation of the above halogenated ethers with many aldehydes and ketones, in presence of magnesium and a zinc-copper couple. The glycol derivatives are converted into aldehydes by treatment with acid as described in the main patent (this J., 1905, 345). The following are among the new aldehydes obtained by this method:—Methyl-2-decanal, methyl-2-undecanal, methyl-2-dodecanal, dimethyl-2,5-hexanal, dimethyl-2,3-nonanal, dimethyl-2,4-decanal, methyl-2-dodecene-11-al. —T. F. B.

Dialkylbarbituric Acids; Process for Making —. Akt.-Ges. f. Anilinfabr. Fr. Pat. 349,814, April 12, 1904.

SEE Eng. Pat. 8302 of 1904; this J., 1905, 289.—T. F. B.

Camphene; Production of — by the use of Nicotine. Soc. Gen. pour la Fabrication des Matières Plastiques. Fr. Pat. 349,815, April 12, 1904.

THE process is for the production of camphene by heating pinene hydrochloride with a little more than the theoretical amount of nicotine for several hours in an autoclave at 210° C.—E. S.

Pinene Hydrochloride; Continuous Production of —. Soc. Gen. pour la Fabrication des Matières Plastiques. Fr. Pat. 349,816, April 12, 1904.

A SERIES of lead chambers are connected by pipes, which can be surrounded by refrigerants. The oil of turpentine gravitates downwards, the outlets of the chambers being so arranged that the chambers are always partly filled. Hydrochloric acid gas circulates from below upwards, bubbling through the liquid in each chamber. —E. S.

Ureas (or Pyrimidines); Process for Producing Cyclic —. E. Merck. First, Second and Third Additions dated Nov. 8, 1904, to Fr. Pat. 349,353, Nov. 8, 1904. Under Int. Conv., Nov. 14, 1903, Jan. 28, 1904 and Jan. 28, 1904, respectively.

SEE Eng. Pats. 22,128, 22,126 and 22,127 of 1904; this J., 1905, 689.—T. F. B.

Camphor; Process for Preparing — from the Esters of Isobornyl. Chem. Fabr. auf Actien, vorm. E. Schering. Fr. Pat. 349,398, Dec. 8, 1904. Under Int. Conv., Dec. 21, 1903.

SEE U.S. Pat. 790,601 of 1905, preceding these.—T. F. B.

Alcohol; Recovery of Vapours of — either Pure or Mixed with other Gases or Volatile Solvents. Soc. J. Jean et Cie and G. Raverat. First Addition, dated Dec. 31, 1904, to Fr. Pat. 345,138, July 25, 1904.

THE process for absorbing alcoholic vapours by means of concentrated sulphuric acid (see this J., 1904, 1231) can be extended to the recovery of other bodies mixed with the alcohol, especially camphor and turpentine. These bodies are absorbed by the acid simultaneously with the alcohol and can be precipitated by diluting with water, the recovered alcohol remaining in solution. —J. F. B.

Hydrocarbons; Process of Obtaining Sulphurised —. Cie Morana. Fr. Pat. 349,833, Dec. 31, 1904.

SULPHURISED hydrocarbons are prepared by the action of ketones and aldehydes in the presence of metallic sulphide, or polysulphide, or ammonium sulphide or hydrosulphide. The oxygen of the ketone is replaced by sulphur and at the same time condensation with aldehyde grouping takes place with the elimination of water.—E. S.

Castor Oil Product Miscible with Mineral Oil; Preparation of a —. Soc. anon. Française Stern-Sonne pour la Fabrication des Vaseline, Huiles et Graisses Industrielles. Fr. Pat. 350,511, Jan. 3, 1905, 2 pages 741.

Dialkylmalonic Amides; Process of Producing Compounds of —. E. Merck. Fr. Pat. 350,600, Jan. 8, 1905. Under Int. Conv., Jan. 8, 1904.

DIALKYL MALONIC amides have hitherto been prepared by the action of ammonia on dialkylmalonyl chloride. It is now found that the cyanogen group of dialkylcyanoacetamides, dialkylcyanoacetylureas, and dialkylcyanoacetic esters may be converted into the CO group by gently heating with fairly strong sulphuric acid or hydrochloric acid. One part of diethylexacetamide is heated with 5–10 parts of concentrated sulphuric acid (preferably diluted with a little water) to 100° C. for 1 hour; the product is poured into water and the diethylmalonic amide is filtered off.—T. F.

Methylene Salicylacetate and Process of Preparing —. Valentiner and Schwarz. Fr. Pat. 350,623, Jan. 3, 1905.

SALICYLACETIC acid (m. pt. 135° C.) is dissolved by heating in half its weight of 40 per cent. formaldehyde solution. The solution sets on cooling to a solid which is broken up and recrystallised from water. The product consists of methylene salicylacetate $HOOC.C_6H_4.OCH_2.COCH_3$ of m. pt. 108° C.; it possesses the power of reducing ammoniacal silver nitrate.—T. F.

GERMAN PATENTS.

Perfumes Having the Odour of Violets from Pseudoionone and its Derivatives; Method of Preparing —. P. Alexander. Ger. Pat. 157,647, Feb. 9, 1902.

THE so-called pseudo compounds obtained by condensing citral or lemon-grass oil with acetone or its homologues, or with acetoacetic ester or similar derivatives of acetone, by means of acids or alkalis, are converted into compounds possessing the odour of violets, by heating them with water, or with some indifferent solvent, to temperatures considerably above 100° C. (*e.g.*, 170°–190° C.).—T. F. B.

Alkylapomorphinium Salts; Process for Producing Easily Soluble, Stable —. R. Pschorr. Ger. Pat. 158,900, July 30, 1903.

STABLE, easily soluble alkylapomorphinium salts may be obtained either by the action of the heavy metal salt of the corresponding acid on apomorphine-iodo-alkylate by treating the free quaternary base with acids, or by the action of alkyl halides or alkyl esters of oxy acids on apomorphine. The chloromethylate, bromomethylate, and methyl nitrate are described.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Emulsions of Mercury Salts [Oxalate]. L. Castelli. Soc. Fotograf. Ital., 1905, 2. Through Phot. M., 1905, 42, 169–170.

STABLE mercury oxalate emulsions may be obtained by adding 200 c.c. of a hot, 1 per cent. solution of oxalic acid to a solution of 8 grms. of mercuric nitrate in 50 c.c. of water, washing the precipitate till free from acid, and incorporating it, at a temperature of about 40° C., with a solution of gelatin, 10 grms., and sodium chloride, 5 gr.

r, 50 c.c. Ammonium oxalate may be used in place of acid. Emulsions of fine grain are best obtained by a 10 per cent. mercuric nitrate solution and a 1 per cent. oxalic acid solution, mixing them at 80° C., adding the washed precipitate to the above gelatin solution, diluted to 350 c.c. The mixture is allowed to stand for several days, when the emulsion is passed through muslin and washed in the usual manner.—T. F. B.

Bromide Plates and Papers: Action of Stannous Chloride on —. R. Namias. Phot. Korrr., 1905, 42, 176. Chem.-Zeit., 1905, 29, Rep. 176.

Solution of 1 part of stannous chloride in 200,000 of water will reduce the silver in a bromide emulsion a few minutes, like an ordinary developer, whilst stronger solutions, allowed to act for a sufficient time, fog and destroy definition like over-exposure to light. This behaviour is held to militate against the old theory, since not more than 0.1 per cent. silver bromide can be reduced to sub-bromide by a minute quantity of stannous chloride present. Bromide plates and papers immersed in a 3 per cent. solution of the stannous chloride and exposed to light, will furnish a direct negative which resists the action of sodium thiosulphate, thus making possible to obtain direct positives with plates and papers. The resulting pictures being better than those obtained with oxalic acid, the author believes that in the latter case causes the formation of silver chloride, but that metallic silver is deposited when the stannous chloride is used.—C. S.

Fluorescence: Sensitising Properties of some New —. K. Kieser. Z. wissen. Phot. Through Phot. Mitt., 1905, 42, 188—190.

Series of dyestuffs obtained by König by treating with various amines the reaction products of pyridine and ethyl iodide were examined as to their colour sensitising properties. The best concentration for the solutions found in all cases to be about 1 in 25,000. Most dyestuffs caused considerable increase of sensitiveness towards the blue end of the spectrum; the sensitising effect of each was found to be destroyed by addition of quantities of ammonia. The dyestuff from bromopyridine and *p*-phenetidine exhibited the best results, the sensitiveness having "maxima" at about wavelengths, 570, 630, and 700. It is considered equal in sensitiveness to the isocyanine class of dyestuff. The dyestuffs from bromopyridine and β -naphthylamine, and from mercuric and *o*-anisidine, showed a maximum at wave length 600; the sensitiveness towards the red end of the spectrum was fairly well marked. The other dyestuffs showed a most increase in sensitiveness to blue rays, with decrease of red sensitiveness.—T. F. B.

Photographs: Coloured —. G. Lippmann. Comptes rend., 1905, 140, 1508—1509.

Photographs taken by the author's method on a sensitive plate developed by a mirror of mercury show colours whatever the nature of the film. If the film be cellulose acetate, the image can be developed by washing with water; but the colours, which come out during the washing, disappear when the film dries, and they are brought back at will by again wetting the film. If the film be wetted with a solution of potassium iodide, the colours remain after the solution has dried, and they are then very feeble; but if the film be developed with 20 per cent. silver nitrate solution, the colours reappear in a particularly brilliant form, and the film can now be washed and dried without any fading taking place. No doubt the uneven distribution in the film of silver iodide is the cause of this; the colours seen in transmission are now changed into the complementary colours seen by reflexion. If a similar treatment could be applied to gelatin-bromide films, coloured prints could then be produced from negatives in an ordinary photographic frame. (See also this J., 1891, 483; 1893, 464; 1895, 400; 1900, 273; 1901, 1238.)—J. T. D.

ENGLISH PATENTS.

Chromic-Gelatin Processes in Photography: Improvements —. L. Strasser, Charlottenburg, Germany. Eng. Pat. 17,192, Aug. 5, 1904.

PAPER, coated with gelatin hardened by alum, and containing some substance which is visibly reduced by light (e.g., iron ammonium citrate), is exposed under a negative until the detail is just visible in the light parts of the print. A paper coated with bichromated, pigmented gelatin is then pressed on the above print, and the paper is developed in hot water as in the usual pigment process. After a short time the pigment paper can be removed from the original paper, leaving the coloured image on the latter; this may now be transferred to glass, wood, &c. In a modification of the above method, the sensitive salt may be applied to a temporary support coated with dextrin or similar substance; in this case the print will finally be obtained on the pigment paper, whence it may be transferred to its permanent support. The image may be strengthened by impregnating with the bichromated pigmented gelatin such substances as sodium acetate or potassium thiocyanate.—T. F. B.

Reducing Agents or Compositions for use in Photography. H. E. Smith, London. Eng. Pat. 6276, March 24, 1905.

COBALTAMINES or double salts of cobalt nitrite with alkali nitrites are employed in sulphuric acid solution for reducing the density of the photographic image; the action of these compounds is said to be selective to the required degree. For further details, see this J., 1905, 635.

—T. F. B.

FRENCH PATENT.

Photographic Paper. E. C. Morgan. Fr. Pat. 349,731, Dec. 30, 1904. Under Int. Conv., Dec. 2, 1904.

XXII.—EXPLOSIVES, MATCHES, Etc.

Explosion of Dynamite: Effects of the Explosion of — at a Distance. L. Thomas. La Nature, Paris, 1904, 180—181. Proc. Inst. Civil Eng., 1905, 159, 53—54.

From the results of experimental explosions of large charges of dynamite in the open air, it is concluded that no dangerous and destructive effects are produced beyond a radius varying from 328 to 1640 ft., according to the weight of the charge. In the experiments, the dynamite was enclosed in packing cases, each holding 55 lb. of the explosive, and charges of 55, 110, 551 and 2204 lb. respectively were exploded. The direct destructive effects of the different charges were limited to distances of 57.4, 131.2, 180.4 and 410.1 ft. respectively; beyond these limits were small neutral zones, and beyond the latter, zones in which the effects of the counter-shocks only were manifested. The results indicate that the distance within which the destructive action of the explosion is felt, increases in proportion to the square root of the weight of the charge.—A. S.

Acetylcellulose. C. Haussermann. XIX., page 748.

UNITED STATES PATENTS.

Explosive Powder: Apparatus for the Manufacture of Strips of —. F. J. du Pont, Wilmington, Del. U.S. Pat. 790,918, May 30, 1905.

THE paste is placed in a cylinder and is forced by a plunger through a nozzle which feeds it between two rollers travelling at the same rate of speed and from which it issues as a sheet.—G. W. McD.

Explosive Composition. A. Frank, Charlottenburg, Germany. U.S. Pats. 792,511 and 792,512, June 13, 1905.

FRENCH PATENTS.

Explosives; Impts. relating to — C. Girard.
Fr. Pat., 349,635, April 5, 1904.

FOR the purpose of obtaining increased safety in manufacture and dispensing with the use of oil, advantage is taken of the lowering of the melting point of molecular mixtures of azo and nitro bodies of the aromatic series to produce, in conjunction with oxidising bodies, a series of explosives. If azobenzene (m.pt. 66.5° C.) is added to dinitrotoluene (m.pt. 71° C.), the mixture has a melting point of only 34.5° C. The following are given as examples:—Potassium chlorate (72 parts), azobenzene and dinitrotoluene (28 parts). Ammonium nitrate (63 parts), azobenzene and dinitrotoluene (37 parts). Potassium chlorate (65 parts), azobenzene and picric acid (35 parts). By the addition of similar mixtures to nitroglycerin explosives they can be worked up at lower temperatures and are less susceptible to freezing at low temperatures. A molecular mixture of trinitro-cresol and picric acid, melting at 70° C., can advantageously be used for filling shells.—(G. W. McD.)

Self-Combustible Compound and its Applications. H. Maxim. Fr. Pat. 349,604, Dec. 27, 1904.

SEE Eng. Pat. 28,376 of 1904; this J., 1905, 457.—T.F.B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS, Etc.

FRENCH PATENT.

Carbon Monoxide; Apparatus for the Detection and Determination of — A. Lévy and A. Pecoul. Fr. Pat. 349,714, Dec. 29, 1904.

THE process depends upon the liberation of iodine from iodic acid by carbon monoxide, and the absorption of the iodine in a solvent with which it forms a coloured solution. The gas containing the carbon monoxide is led first through a filter of glass wool and then through a heated U-tube containing pure iodic anhydride. The iodine set free is carried forward by the gas and is led through an absorption-tube containing some chloroform, carbon bisulphide or other suitable liquid, covered with a column of distilled water, about 8 cm. high, to prevent evaporation. The chloroform or carbon bisulphide acquires a depth of tint proportional to the amount of iodine set free by the carbon monoxide, and the amount of the latter can be readily determined by comparing the colour with that of a standard solution.—A. S.

INORGANIC—QUANTITATIVE.

Gold; Quantitative Separation of — from other Metals by Salts of Hydrazine and Hydroxylamine. P. Jannasch and O. von Mayer. Ber. 1905, 38, 2129–2130. (See this J., 1904, 685, 729, 760.)

GOLD is precipitated quantitatively from neutral, acid or alkaline solutions by hydrazine hydrochloride; the precipitation takes place at the ordinary temperature, and the precipitate is usually reddish-brown. Hydroxylamine may be used instead of hydrazine; the precipitation is in this case carried out in a solution of hydrochloric acid and is only complete after long heating on the water-bath. By using hydrazine or hydroxylamine, gold may be separated from potassium, sodium, barium, strontium, calcium, magnesium, aluminium, chromium, zinc, manganese, iron, uranium, nickel, cobalt, cadmium, mercury, lead and copper.—C. E. F.

Metals of the Platinum Group; Action of Hydrazine and Hydroxylamine Salts on —, and the Quantitative Separation of these Metals from Gold. P. Jannasch and O. von Mayer. Ber. 1905, 38, 2130–2131. (See preceding abstract.)

PLATINUM is not precipitated from its solutions by hydroxylamine hydrochloride, and can be separated from gold, which, in solution of hydrochloric acid is

precipitated. Platinum is precipitated when washed with hydrazine hydrochloride and sodium hydroxide. Palladium is similar to platinum in these reactions. Iridium, rhodium, osmium and ruthenium are separated from gold by hydroxylamine hydrochloride, which does not give any precipitate. Hydrazine hydrochloride precipitates rhodium completely, but not iridium, osmium and ruthenium.—C. E. F.

Nitrous Acid; Volumetric Determination of — by Tetravalent Cerium Salts. G. Barbieri. Chem. Zeit., 1905, 29, 668–669.

THE orange-yellow solutions of ceric salts are decolourised by alkali nitrites without evolution of gas, according to the equation:

The reaction is quantitative and takes place rapidly at the ordinary temperature. The best results are obtained by oxidising the nitrites with excess of ceric sulphate and by determining the excess of the latter by titrating with potassium iodide and titrating the iodine liberated. The presence of nitrates and of salts of earths other than ceria has no influence on the results.—J. F.

Hydrogen Peroxide; Determination of — in the Presence of Potassium Persulphate. J. A. N. Friend. Soc. Proc., 1905, 21, 185.

THE author has previously shown (Chem. Soc. Trans., 1904, 85, 597) that hydrogen peroxide cannot be accurately determined in the presence of potassium persulphate by titration with permanganate in the ordinary way, but, however, a slight excess of permanganate is rapidly reduced to the mixture of hydrogen peroxide and potassium persulphate, and the excess determined iodometrically with thiosulphate, very accurate results can be obtained in the presence of not more than 0.08 gm. of potassium persulphate. (Compare also this J. 1905, 561.)—A. S.

Mercury; Volumetric Method for the Determination of — E. Rupp. Arch. Pharm. 1905, 243, 300–302.

THE following method is specially suitable for the determination of mercuric chloride in pharmaceutical and surgical preparations.

Ten c.c. of N/1 sodium hydroxide solution are mixed with about 5 c.c. of formaldehyde solution, approximately 35 per cent. in strength, the mercuric chloride solution to be determined is added, and the mixture is allowed to warm for 10 to 15 minutes on the water-bath. After cooling, it is acidified with excess of acetic acid; a known volume, in excess, of N/10 iodine solution is run in, the flask stoppered, and well rotated for about 5 minutes, so as to bring the precipitated mercury into intimate contact with the iodine solution. When combination is complete, the excess of iodine is titrated in the usual manner, with thiosulphate solution.—J. B.

ORGANIC—QUALITATIVE.

Aconitine; New Reagent for the Detection of — P. Alvarez. Comptes rend. 1905, 140, 1540–1541.

THE substance (0.5 to 2.0 mgrms.) is placed in a porcelain crucible, 5–10 drops of bromine are added, and the mixture is gently warmed. Then 1–2 c.c. of fuming nitric acid are added, and the whole is evaporated to dryness on the water-bath, adding a drop of bromine now and then as the liquid becomes decolorised. The residue 0.5–1 c.c. of a saturated alcoholic solution of potassium hydroxide is added, and the whole is evaporated to dryness, giving a red or brown residue if aconitine be present. After cooling, 5 or 6 drops of a 1 per cent. aqueous solution of copper sulphate are added and the residue is well moistened with it, when an intense green colour is struck.—J. T. D.

Milk; Detection of Formalin in — Utz. Chem. Zeit., 1905, 29, 669.

THE author has established that the addition of formaldehyde to milk vitiates the tests used to distinguish between raw and boiled milk only when the prop-

aldehyde is considerably in excess of that employed for derivative purposes.

A reagent is proposed for the detection of formaldehyde in milk; this is the same as that used by Winkel as ferments, *viz.*: vanillin and hydrochloric acid. Equal parts of milk and hydrochloric acid, sp. gr. 1.18, warmed with a few crystals of vanillin, a fine or raspberry-red coloration is developed. If, however, a mere trace of formaldehyde be present, the coloration becomes yellow.

It is stated to be a most distinct and delicate test; reactions can be obtained by means of piperonal roxybenzaldehyde, but the vanillin test is the best. Reactions are not applicable for the detection of aldehyde in liquids other than milk.—J. F. B.

ORGANIC—QUANTITATIVE.

Analysis of Organic Compounds: Electrical Method ——. H. N. Morse and L. S. Taylor. Amer. J. 1905, 33, 591–603.

The apparatus is represented in the adjoining figure. The

combustion tube, which is closed at one end, has a length of 15 mm., and an internal diameter of 15 mm. At the other end is a rubber stopper, and through this passes a glass tube *c*, 250 mm. long and 6 mm. in diameter; a glass tube *k* through which the products of combustion pass to the absorption apparatus; (3) a stout platinum wire (No. 18, B & S gauge), which extends from

the porcelain tube *c* is joined outside the combustion tube by means of rubber tubing to a branched glass tube. One branch *d* the oxygen or air for the combustion and through *g* a piece of stout platinum wire passes from the ends to *h*. A thinner platinum wire (No. 29, 1.75 m. and weighing about 2.5 grms., is joined to the other platinum wire at *h*; it passes through the tube and returns on the outside of this as a coil to the other platinum wire at *j*.

A roll of copper wire gauze 60 mm. long, and the tube placed next the closed end as shown.

On carrying out a combustion, the boat with substance is placed in the tube, and the absorption apparatus fixed on. The current of oxygen is admitted, and the electric current through the platinum coil is closed. The current is first, but is gradually increased until the coil gets a bright red heat; *b* is then heated by a gas flame, and the substance also. One half of the copper wire is kept oxidized throughout the combustion. The tube is driven out by air after the combustion is complete and the electric current is gradually decreased. The apparatus occupied in carrying out the combustion need not be changed half an hour. When nitrogen or halogens are present, a roll of copper gauze or silver foil is introduced into the oxidized copper spiral.

The advantages claimed for this method over the ordinary method are the following: (1) the small dimensions of the apparatus, (2) less waste of heat energy, (3) short time occupied by the combustion.—C. E. F.

Volumetric Determination of Reducing ——. Ling and T. Rendle. Analyst, 1905, 30, 182–188.

The authors recommend a new indicator—ferrous thiocyanate—which they have employed with great success for the determination of the end-point of the titration of

Fehling's solution with solutions of reducing sugars. This indicator is prepared in the most sensitive form in the following manner:—1 gm. of ferrous ammonium sulphate and 1 gm. of ammonium thiocyanate are dissolved in 10 c.c. of water at a temperature of 45–50° C., and the solution is immediately cooled; 5 c.c. of concentrated hydrochloric acid are added, and the slight reddish colour due to the presence of ferric salts is discharged by the addition of a trace of zinc dust; the indicator becomes red after a few hours by absorption of air; it can be decolorised again by more zinc dust, but its delicacy becomes impaired after it has been decolorised several times.

For the determination of sugars the authors prefer to use the Fehling's solution in the undiluted form. Ten c.c. of freshly-mixed Fehling's solution are raised to the boiling point in a flask and the sugar solution, the concentration of which should be so adjusted that 20–30 c.c. correspond to 10 c.c. of Fehling's, is run into the boiling liquid in small amounts, the mixture being boiled after each addition. Towards the end of the titration, drops of the liquid are withdrawn by means of a glass rod and rapidly brought in

contact with drops of the indicator previously "spotted" on a porcelain tile; when all the cupric salt is reduced, the mixture of the two drops ceases to produce a red stain. This method has the advantage of obviating the necessity of filtration, but the titration and the "spot" tests must be made very rapidly in order to avoid oxidation.

It is claimed that by this method more accurate results are obtainable with commercial sugars than by the gravimetric method.—J. F. B.

Sugar; Determination of ——. with Fehling's Solution. F. P. Lavalle. Ber., 1905, 38, 2170.

In the volumetric determination of reducing sugars with Fehling's solution, the author recommends the addition of an excess of caustic alkali to the latter to prevent the precipitation of the cuprous oxide. By this means, a completely colourless solution is obtained when the titration is completed, and the end point is rendered much more distinct. The actual details are as follows:—Ten c.c. of ordinary Fehling's solution, 30 c.c. of sodium hydroxide solution (1:3) and 50 c.c. of water are mixed, boiled, and titrated as usual with the sugar solution. The titration is finished when the last drop of sugar solution added causes the faint blue coloration of the Fehling's solution to disappear. The method is stated to be quick and accurate.—W. P. S.

Spirits; Determination of Higher Alcohols in ——. I. P. Schidrowitz and F. Kaye. Analyst, 1905, 30, 190–194.

The paper deals with the Beckmann nitrite method of determining higher alcohols (this J., 1900, 383; 1902, 193). Working according to Beckmann's directions upon a selected alcohol, the authors obtained an obviously impossible result corresponding to 0.8 per cent. of amyl alcohol. This error was recognised as being due to the extraction of a portion of the ethyl alcohol by the carbon tetrachloride. By making the conditions of extraction identical with those of the Allen-Marquardt method, *i.e.*, extracting a mixture of alcohol and brine of a sp. gr. of 1.10 with carbon tetrachloride, the authors succeeded in

* In the original paper "50 c.c." should read "5 c.c."

reducing the error, so that the apparent proportion of amyl alcohol was 0.7 grm. per litre; but a simultaneous determination by the Allen method gave a result of only 0.12 grm. per litre. Hence it is concluded that, owing to the extraction of some of the ethyl alcohol and to its determination as apparent amyl alcohol in the form of nitrite, the Beckmann method in its present condition is unworkable.—J. F. B.

Formaldehyde: Gasometric Determination of ——. G. B. Frankforter and R. West. *J. Amer. Chem. Soc.*, 1905, 27, 714-719.

The following method of carrying out the determination of formaldehyde by Blank and Finkenbemer's process (this *J.*, 1899, 79) is described. A Scheibler-Finkner calometer, with a graduated tube of 300 c.c. capacity, was employed. One c.c. of the formaldehyde solution of known specific gravity was placed in the side tube of the generator, 10 c.c. of hydrogen peroxide and 20 c.c. of N/1 potassium hydroxide solution being placed in the body of the generator. After bringing the water in the measuring tube to the zero mark and allowing the temperature to become constant, the solutions were gradually mixed. The volume of the liberated hydrogen was read off when the temperature of the generator vessel had again become constant. The results obtained agreed well with those yielded by other methods. Satisfactory results were also obtained by substituting freshly-prepared sodium peroxide solution for the hydrogen peroxide. The presence of a little alcohol in the formaldehyde solution tends to give low results unless larger quantities of hydrogen peroxide and potassium hydroxide be used. It is shown that the evolved gas consists of pure hydrogen.—W. P. S.

Pyridine: Purification of ——. [also, *Determination of Ammonia in* ——.] L. Barthe. *Ill.*, page 722.

Acetyl-methylcarbinol: Presence (and Determination) of ——. in certain Commercial Vinegars. Pastureau. *XVII.*, page 745.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Radium: Production of ——. from Uranium. F. Soddy. *Phil. Mag.*, 1905, 9, 768-779.

EXPERIMENTS were made with a solution of 1 kilo. of uranium nitrate, from which radium had been practically completely removed by repeated precipitation of small quantities of barium sulphate in the solution. The solution was kept in a closed bottle, and observations were made over a period of about eighteen months. It was found that the uranium, under these conditions, gradually developed the power of producing an emanation identical in properties with that obtained from radium; and the author states that there can be no doubt that the emanation results from radium produced from the uranium. The quantity of radium produced was very minute, being equivalent to about 1 atom per 3×10^{11} atoms of uranium.—A. S.

Mineral Springs: Radioactivity of Bohemian ——. H. Mache and S. Meyer. *Monatsh. f. Chem.*, 1905, 26, 595-625.

THE authors made a detailed examination of the various springs in the Karlsbad, Marienbad, Teplitz-Schönau-Dux, and Franzensbad groups, and also waters from the mines at St. Joachimsthal. The results were as follows:—1. The amount of emanation in a given locality varies enormously from spring to spring; the comparative figures vary at Karlsbad from 38.4 to 0.99, at Marienbad from 6.78 to 0.66, at Teplitz-Schönau-Dux from 8.73 to 3.13, and at Franzensbad from 0.96 to 0.13. At Karlsbad, the "Eisenquellen," which are cold springs in a hot spring district, show more emanation than the surrounding hot springs. 2. In the case of the St. Joachimsthal waters the quantity of emanation increases with the depth from which the water is taken; the deepest of these shows the highest content yet found in a spring (6×10^3 - 185 electrostatic units). 3. The gas evolved from those springs

which contain it in small quantity has a higher content of emanation than the water; but in the case of springs rich in gas this is not the case. The authors conclude that the gas derives its emanation from the water, that in the very gaseous waters equilibrium in this respect is not reached when the gas escapes. 4. The diminution of amount of emanation follows an exponential law, with constants practically identical those of the radium-emanation. This, and the behaviour of the induced radioactivity leaves no doubt that the emanation is identical with that of radium.—J. T. D.

New Books.

Forty-First Annual Report on Alkali & Co. BY THE CHIEF INSPECTOR. Proceedings during year 1904. Presented to the Local Government and to the Secretary for Scotland. Eyre and Spence, East Harding Street, Fetter Lane, E.C. 4, 1905. Wyman and Sons, Ltd., Fetter Lane, E.C. 4, and 32, Abingdon Street, Westminster, S.W.; Oliver and Boyd, Edinburgh; E. Ponsonby, Grafton Street, Dublin. Price 8d. (See page 722.)

Report on the Manufacture of Paints and Coatings Containing Lead, as Affecting the Health of Operatives Employed. By T. M. Legge, D.Sc., H.M. Medical Inspector of Factories. Darling and Sons, Ltd., 34-40, Bacon Street, E.; Wyman and Sons, Ltd., Fetter Lane, E.C. 4, and 32, Abingdon Street, Westminster, S.W.; Oliver and Boyd, Edinburgh; E. Ponsonby, 116, Grafton Street, Dublin. Price, 11½d. (See page 742.)

Mines and Quarries: General Report and Statistics for 1904. Part I. District Statistics. [Cd. 2497.] Wyman and Sons, Ltd., Fetter Lane, E.C. 4, 1905.

THIS report, just issued by the Home Office, contains 48 pages of statistics of the persons employed, output, and accidents at mines and quarries in the United Kingdom in 1904, arranged according to the Inspection Districts, to which are added "Comparative Tables" giving the number of persons employed, output and accidents in mines for each year from 1873 to 1904.

Annual Statement of the Trade of the United Kingdom with Foreign Countries and British Possessions. 1904. Vol. I. [Cd. 2497.] Price 7s. 7d.

THIS is the first volume of the statement of the trade of the United Kingdom for the year 1904 and contains abstract tables showing the total imports and exports of every article which is separately enumerated in the official classification, as well as detailed showing the quantity and value of the imports and exports of each article from and to each country; are given in each case not only for the year 1904, but for each of the four preceding years. A new feature in the present issue of this return is an introductory statement explaining the bases on which the tables are compiled, and giving an outline of their scope and arrangement.

Several alterations have been made in the classification of imports and exports; amongst the more important of these it may be noted that in the import table the headings for "chemical products," "musical instruments," "seed oil," "chinaware or porcelain and earthenware," "hardware," "iron and steel," have been subdivided in greater detail than was formerly the case. The statements of the exports of the following classes of goods are also shown in greater detail, viz., con-

oil-seed cake, chemicals, chinaware or porcelain-ware, hollow-ware and musical instruments. Lists of the shipments of certain classes of iron goods and of wool have been re-classified. The H. of this statement will include tables of imports and exports of the United Kingdom, arranged by countries from and to which they were shipped, as the imports and exports at each port, &c.

ORE DEPOSITS IN FOREIGN COUNTRIES. Reports. [Cl. 2553.] Price, 2s. 4d.

A return has been prepared in the Commercial Intelligence Branch of the Board of Trade; it contains a digest of information which has been received from H.M. Representatives in foreign countries as the result of inquiries made by the Board of Trade, through the Foreign Office, at the suggestion of the British Iron Trade Association. The data comprise particulars as to the geographical position and extent of iron ore deposits in various countries, the effective means of transport, cost of labour, analyses, &c., together with other particulars likely to be of interest to those interested in the iron trade in this country. A number of samples, maps and miscellaneous information forwarded by H.M. Representatives in illustration of their reports may be seen at the office of the Commercial Intelligence Branch.

A REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1904. Part I. Reports. Presented to both Houses of Parliament by Command of His Majesty. [Darling and Son, Ltd., 34—40, Abchurch Lane, London, E.; Wyman and Sons, Ltd., 15, Abchurch Lane, E.C., and 32, Abingdon Street, Westminster, S.W.; Oliver and Boyd, Edinburgh; E. Sonby, 116, Grafton Street, Dublin. 1905. Price 3s.]

KEY TO THE CLASSIFICATIONS OF THE PATENT SPECIFICATIONS OF FRANCE, GERMANY, AUSTRIA, NORWAY, SWEDEN, AND SWITZERLAND IN THE LIBRARY OF THE PATENT OFFICE. Second Edition. [Patent Office Library Series, No. 1.] Darling and Son, Ltd., 34—40, Abchurch Lane, London, E.; Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C. 1905. Price, 6d.

This present handbook is an enlarged edition of the series No. 1 (Key to the Classifications of the French Patent Specifications) and No. 5 (Key to the Classification of Patent Specifications of Germany, Austria, Denmark, and Norway) of the Patent Office Library Series.

CA DELLE SOSTANZE COLORANTI. TEORIA ED APPLICAZIONE ALLA TINTURA DELLE FIRRE TESSILI. ARTURO PELLIZZA. Ulrico Hoepli. Editore Librai a Real Casa. Milan. 1905. Price L.5.50.

A small volume, pocket book size, containing 472 pages of subject matter, and alphabetical index of subjects. In the treatment of the subject, that of the dyestuffs first, and finally that of the textile fibres. A. Mineral coloring matters. B. Organic coloring matters. C. Nitrophenolic dyestuffs. II. Quinone-oxime (Nitroso) dyestuffs. III. Azoxy-group. IV. Azo-group. V. Hydrazo group and Derivatives. VI. Thio-azo Group. VII. Imino group. VIII. Triphenylmethane dyestuffs. IX. Quinonoid Group. X. Unclassified Group: unknown constitution, &c., as Murexide, Canarin, &c. Continuation of X. Then follow Kostanecki's classification, and a Scheme for the Qualitative Identification of Organic Dyestuffs.

NOUVEAUX CHIMIQUES POUR 1905. Nouveaux produits de Laboratoires. Méthodes Nouvelles de recherches Appliquées à la Science et à l'Industrie. MILLE POULENC, D.és Sc. J. B. Baillière et Fils, 19, rue de la Harpe, Paris. 1905. Price, Fr.4.

A small volume, containing 326 pages of subject matter, 180 illustrations, and an alphabetical index of subjects.

The contents are classified as follows: I. General applications of Physics and Chemistry. II. Various items of Laboratory Apparatus. III. Electricity. IV. Chemical Analysis. V. Bacteriology.

SPECTROSCOPY. By E. C. C. BALY, F.R.S., Lecturer on Spectroscopy and Assist.-Prof. of Chemistry, University College, London. Longmans, Green and Co., 39, Paternoster Row, London. 1905. Price, 10s. 6d. New York and Bombay.

A large volume, containing 550 pages of subject matter, with 158 illustrations in the text, and four large plates at the end, and also an Appendix. The volume terminates with an alphabetical Index of subjects and authors. The subjects treated of may be classified as follows:—I. and II. Historical. III. The Slit, Prisms, and Lenses. IV. The Complete Prism Spectroscope. V. Prism Spectroscope in Practice. VI. The Diffraction Grating. VII. The Ruled Grating in Practice. VIII. The Infra-red and Ultra-violet Regions. IX. The Application of Interference Methods to Spectroscopy. X. Efficiency of the Spectroscope. XI. The Photography of the Spectrum. XII. The Production of Spectra. XIII. Nature of Spectra. XIV. The Zeeman Effect. XV. Series of Lines in Spectra. XVI. Change of Wavelength. XVII. Rowland's Grating Ruling Engines. APPENDIX. Recipes for Solutions for Silvering Glass Mirrors.

THE SYNTHETIC DYESTUFFS AND THE INTERMEDIATE PRODUCTS FROM WHICH THEY ARE DERIVED. By J. C. CAIN, D.Sc., and J. F. THORPE, Ph.D., Lecturer on Colouring Matters in the Victoria University of Manchester. Chas. Griffin and Co., Ltd., Exeter Street, Strand, London, W.C. 1905. Price, 16s. nett.

A LARGE 8vo volume containing 361 pages of subject matter, 17 additional pages of Tables of Synthetic Dyestuffs, 12 additional pages of Tables of Atomic Weights, Specific Gravities and Strengths of Acids, Alkali Hydroxides, Tannic Acid, and various Saline Solutions, &c. List of Errata and Addenda, and the Alphabetical Index of subjects. There are 13 illustrations.

The Work consists of three parts. I. *Theoretical*. Description of the Intermediate Products and Dyestuffs. II. *Practical*. Methods of Preparation of the more Important Intermediate Products and Dyestuffs, on the Laboratory Scale. III. *Analytical*. The Analysis and Identification of Intermediate Products and Dyestuffs, together with Methods for Detecting Dyestuffs on the Fibre.

I. (i) Coal Tar: Its Occurrence and Purification. (ii) Nitration (iii) Sulphonation. (iv) Amino Compounds. (v) Hydroxyl Compounds. (vi) Carboxyl Compounds and Aldehydes. (vii) Application of the Dyestuffs. (viii) Classification. (ix) Nitroso-Dyestuffs (Quinone-oximes). (x) Nitro-dyestuffs. (xi) Azo-Dyestuffs. (xii) Hydrazone-Dyestuffs. (xiii) Auramine. (xiv) Triphenylmethane Dyestuffs. (xv) Pyromine Dyestuffs. (xvi) Acridine Dyestuffs. (xvii) Oxyketone Dyestuffs. (xviii) Diphenylamine Dyestuffs. (xix) Quinoxaline Dyestuffs. (xx) Thiazol Dyestuffs. (xxi) Quinoline Dyestuffs. (xxii) Indigo. (xxiii) Sulphur or Sulphide Colours. (xxiv) Xanthone Dyestuffs. (xxv) Short History of the Synthetic Colouring Matters. II. *Practical*. (xxvi) The Technical Laboratory. (xxvii) and (xxviii) Preparation of Intermediate Products. (xxix) Preparation of Dyestuffs, &c. III. *Analytical*. (xxx) Intermediate Products. (xxxi) Application of the Colouring Matters. (xxxii) Valuation of a Colouring Matter. (xxxiii) Quantitative and Qualitative Analysis of Dyestuffs. (xxxiv) Investigation of Dyestuffs on the Fibre.

Trade Report.

I.—GENERAL.

AUSTRIA-HUNGARY: TRADE OF —

For Off. Ann. Series, No. 3399.

The following return shows the value of certain articles of import during the years 1903-04:

Articles.	Value.	
	1903.	1904.
	£	£
Hides and skins, raw	2,074,000	2,645,000
Coal	3,629,000	3,729,000
Metals	2,362,000	2,733,000
Hogs' grease	91,000	250,000
Paper and paper goods	1,200,000	1,350,000
Chemical products	1,460,000	1,720,000

Copper and zinc are chiefly responsible for the increased importation of metals. Paper (chiefly fine German stationery) and chemical products (especially colours), all showed increased importation in 1904.

The subjoined return shows the value of some articles of export during the years 1903-04:—

Articles.	Value.	
	1903.	1904.
	£	£
Hides and skins, raw	1,966,000	2,012,000
Brown coal	2,799,000	2,570,000
Paper and paper goods	1,458,000	1,466,000
Leather goods	2,250,000	1,980,000
Mineral oil	380,000	560,000
Chemical products	995,000	987,000
Ironware	1,410,000	1,930,000
Metals and metalware	958,000	1,000,000
Glassware	2,254,000	2,379,000
Earthenware and pottery	929,000	1,029,000

The decreased exportation of coal—to Germany—is accounted for by the interruption during the drought of the navigation of the Elbe.

The export of sugar, which reached its zenith in 1903 with about 710,000 tons, fell in 1904 to 510,000 tons, the decrease being principally in raw and refined sugar to the United Kingdom and raw sugar to America. The rise in price, however, partially covered the loss to the Monarchy.

The leather industry has also suffered, the export of gloves having decreased 187,000*l.*, and that of shoes 665,000*l.*

The exports of petroleum and glass have increased.

NORWAY: CUSTOMS TARIFF OF —.

A reprint of the new Customs Tariff of Norway, embodying the proposals of the Customs Committee, which have been provisionally put into force, can be found in the issues of the *Board of Trade Journal* for May 25th to June 22nd, inclusive (pages 355–360, 407–412, 455–457, 499–501, and 547–559). The above copies

of the *Board of Trade Journal* may be obtained Messrs. Wyman and Sons, Fetter Lane, E.C., price 1*s.* each.

II.—FUEL, GAS, AND LIGHT.

NATURAL GAS AT YAMACHICHE, QUEBEC.

U.S. Cons. Rep. No. 2284, June 15, 1905.

The discovery is reported of a remarkable gas well at Yamachiche. Two companies are at work boring. The work of one of them has been stopped by a gas, salt water, sand and rock that is beyond control. The flow started when the drill had been driven about 280 ft., and was so strong that it forced derrieks, and trappings out of the well and threw a 200 ft. into the air. The flow was preceded by an explosion that shook the ground for a great distance. The work on this well is stopped temporarily. Natural gas is already used for fuel at St. Genevieve, in this district.

IV.—COLOURING MATTERS, Etc.

INDIGO IN JAVA.

For. Off. Ann. Series, No. 3403.

In view of the difficulties experienced during the few years in finding markets for Java indigo, it is feared that the acreage under cultivation will have largely curtailed.

Exports during the past five years have been as follows:—

Year.	Quantity.
	Lb.
1900	1,537,000
1901	1,411,000
1902	1,128,000
1903	1,297,000
1904	1,070,000

IX.—BUILDING MATERIALS, Etc.

MAGNESITE BRICKS; U.S. CUSTOMS DECISION.

June 7, 1905.

Bricks made of magnesite obtained from magnesite are dutiable at 1 dol. 25 c. per ton as "fire brick which is not more than 10 lb. each, not glazed, enamelled, ornamented or decorated in any manner," under paragraph 87 of the tariff. The merchandise had been assessed for duty under the same paragraph at 25 per cent. *ad valorem* as "brick other than fire brick." The Government sought to establish as a fact that fire brick applied only to brick made of fire clay. This contention was not sustained by the Board, who sustained the claim of the importer.—R. W. M.

X.—METALLURGY.

MINERAL OUTPUT OF THE UNITED KINGDOM.

*Mines and Quarries; General Report and Statistics for 1904. Part I., District Statistics [Cd. 2540]. Price 1*s.* 6d.*

The above report contains statistics, where available, of the output of the principal minerals from all mines, from quarries and from certain other workings during the years 1873–1904; the following details are extracted therefrom:—

Year.	Alum. Shale.	Arsenic.	Arsenical Pyrites.	Barytes.	Bauxite.	Chalk.	Chert and Flint.	Clay and Shale.	Coal.	Copper Ore.	Other Precipitate.

MINERAL INDUSTRY OF NEW SOUTH WALES.

Bd. of Trade J., June 15, 1905.

quantity of gold won in New South Wales during the three months of the year 1905 was 84,376 oz., equivalent to 69,906 oz. fine, valued at 296,945*l.*, compared with 103,448 oz. crude (87,048 oz. fine), at 369,755*l.*, during the same period of 1904.

quantity and value of the silver, copper, tin and exported from New South Wales during the first

of this year were as follows:—

Product.	Quantity.	Value.
		£
Ingots, and matte	149,336 oz.	17,038
Lead concentrates, &c.	101,690 tons	536,820
Ingots and ore	1,636 "	102,019
Gold, and ore	563 "	67,358
Australasian and other ports	676,100 "	278,342
Total value	—	£1,001,577

se figures indicate a net increase for the quarter of *l.*, as compared with the corresponding period last year. The exports of silver, silver-lead, &c., show an increase in value of 129,561*l.*, but the value of the coal exported is less by 39,565*l.*. In copper and tin a decrease of 151*l.* and 5,700*l.* respectively, in value is also shown.

BOLIVIA; MINERAL WEALTH OF —.

For. Off. Ann. Series, No. 3388.

M. Consul at La Paz gives in his report for 1904 a list of the minerals found in Bolivia, together with particulars of the districts in which deposits occur.

TIN EXPORT OF JAVA.

For. Off. Ann. Series, No. 3403.

Shipments of Government tin from Java amounted to 9 tons, as against 15,381 tons in 1903 and 10,339 in 1902; while the quantity of private tin shipped was 3,077 tons, as compared with 3,436 tons in 1903 and 3 tons in 1902.

V.—TANNING; LEATHER; GLUE, Etc.

QUEBRACHO EXPORTS FROM ARGENTINA.

U.S. Cons. Rep. No. 2280, June 10, 1905.

The exports of quebracho logs from Argentina for a series of years were, in tons, as follows:—1894, 74,358; 1895, 239,836; 1902, 254,723; 1903, 200,201; 1904, 172,723. Of the exports of 1903, the quantity consigned to Germany was only 4,322 tons, or 15,877 less than in 1902, while the United States received 23,511 tons,

Portugal 30,893, and the United Kingdom 130,747 (11,332 less than in 1902) on British account "for orders." A large portion of this last-mentioned quantity went to Germany. The exports of quebracho extract were as follows during the years given, in tons:—1895, 492; 1900, 5957; 1903, 12,040; 1904, 20,111. In 1903, Germany received 2812 tons (409 more than in 1902), the United States 6352 tons, and the United Kingdom only 1214 tons, besides 200 tons on British account "for orders."

According to the statistical department, the value of quebracho extract in Buenos Aires is 80 *dols.* per ton, and 86 *dols.* per ton on board in a German port, while the value of quebracho in logs is 15.84 *dols.* in Buenos Aires, and 21 *dols.* on board in Germany.

XVI.—SUGAR, STARCH, GUM, Etc.

SUGAR PRODUCTION OF JAVA.

For. Off. Ann. Series, No. 3403.

The following table gives the sugar production of Java in each of the past six years:—

Year.	Quantity.
	Tons.
1899	730,842
1900	710,150
1901	766,342
1902	848,021
1903	883,020
1904	1,064,935

During the year prices steadily advanced from the equivalent of 7*s.* to 9*s.* 4½*d.* per cwt.

Up to the end of 1904 an all round increase of the export to most countries took place. This is specially noticeable as regards shipments to the United Kingdom, India and the United States. On account of the large sugar crops in Queensland and New South Wales proving sufficient for local requirements, Australia has only taken 14,000 tons of Java sugar as against 72,000 tons in 1903. Although the exports to Singapore amount to 28,000 tons, there is reason to believe that a large portion of this is ultimately transhipped to Indian ports. The sugar chiefly exported to India is what is known as superior sugar. It has there to a certain extent supplanted the Austro-Hungarian and German beet sugars. Prospects for the 1905 crop are good, the young cane, according to reports, looking very well, but naturally much depends on the weather.

XVII.—*BREWING, WINES, SPIRITS, Etc.*

SPIRIT: DUTY-FREE — IN GERMANY DURING THE PERIOD OCT. 1, 1903, TO SEPT. 1, 1904.

Z. Spiritusind., 1905, 28, 229.

The amounts of denatured spirit used in the different chemical industries during the period Oct. 1, 1903, to Sept. 1, 1904, are shown in the following table, the increase or decrease compared with the corresponding figures for the preceding year, being given in brackets:—

	Hectolitres
For the manufacture of vinegar	182,509 (— 2,246)
.. .. cellulose	25,007 (+ 2,569)
.. .. ether	67,977 (+ 15,438)
.. .. acetic acid	1,907 (+ 1,443)
.. .. chemical products	48,978 (+ 10,341)
.. .. colour lakes	3,417 (— 1,950)
.. .. varnishes and polishes	69,097 (— 1,511)

The total amount of partially denatured spirit used in the chemical industries and for industrial purposes amounted to 385,946 hectolitres, an increase of about 22,700 hl. over the figures for the preceding year.—A. S.

XIX.—*PAPER, PASTEBOARD, Etc.*

WOOD PULP IN SWEDEN.

For. Off. Ann. Series, No. 3412.

During the latter part of 1903 endeavours were made to raise the prices of wood pulp by limiting the production. At first the results obtained were small, but afterwards prices improved considerably, and in the spring sellers became very hopeful. Their expectations, however, were not realised, for early in the summer wet pulp had frequently to be sold at almost any price obtainable. Ruinously low offers were accepted by exporters until, owing to the drought that prevailed in Scandinavia and elsewhere, the demands increased at the very time that supplies were diminishing. The latter half of the year therefore was characterised by brisk sales and rising prices. The following are the figures quoted per English ton (ton), Gothenburg:—Dry mechanical pulp, from 3*l.* 4*s.* 5*d.* up to 4*l.* 14*s.* 5*d.* Wet mechanical pulp, from 1*l.* 12*s.* 2*d.* up to 2*l.* 4*s.* 5*d.*

In the manufacture of sulphite cellulose, imported sulphur was at one time exclusively employed. Since 1903, however, it has been largely replaced by pyrites, which is now mined in considerable quantities and used for the above-mentioned purpose. The mines at Falun supply the principal works in Central Sweden. The season was a good one and prices steadily increased. It is stated that at the beginning of the present year much of the produce was already sold and that contracts have in some instances been entered into for the delivery of the output not only of 1905, but also of the next two years. Hopes are therefore entertained here that the market for chemical wood pulp will continue to be favourable for some time to come. The prices quoted by the exporters per ton (ton), Gothenburg was stated to have been:—For slightly bleached "lätblekt" sulphite, 7*l.* 4*s.* 5*d.* up to 8*l.* 6*s.* 8*d.*, and for strongly bleached "lätblekt" sulphite, 6*l.* 13*s.* 4*d.* up to 7*l.* 15*s.* 6*d.*

The export of wood-pulp from Sweden during 1903 and 1904 was as follows:—

	1903.	1904.
	Tons.	Tons.
Chemically prepared, dry	224,573	251,427
Chemically prepared, undried	18,016	20,524
Machine pressed, dry	48,585	58,321
Machine pressed, undried	67,139	82,291

WOOD PULP IN NORWAY.

Ed. of Trade J., June 22, 1905.

H.M. Consul-General at Christiania reports that the stocks of both mechanical and chemical wood pulp in Norway are at present very low.

Norway's production of wood pulp in the last three years is estimated to have been as follows:—

1. Chemical wood pulp, calculated dry—

	1902.	1903.	1904.
	Tons.	Tons.	Tons.
Cellulose sulphite	93,000	98,000	105,000
Cellulose sulphate	9,000	0,500	16,000

2. Mechanical wood pulp (for sale), calculated wet

	1902.	1903.	1904.
	Tons.	Tons.	Tons.
	326,000	313,000	290,000

The anticipated production in 1905 of mechanical pulp is estimated at 290,000 tons. Figures showing anticipated production of cellulose in 1905 are available.

Stocks on the 1st January of the three last years are as follows:—

1st January, 1903 ..	24,055 tons, calculated
1st January, 1904 ..	25,178 tons, calculated
1st January, 1905 ..	10,504 tons, calculated

Of the stock left on 1st January this year 7823 tons were sold, thus leaving unsold on that date only 2681 tons.

XX.—*FINE CHEMICALS, Etc.*

QUININE IN JAVA.

For. Off. Ann. Series, No. 3403.

The large quantities of Java cinchona bark offered for sale at the Amsterdam auctions caused a decline in the average result of the auctions being 6.50 c per unit (5 c = 1*d.*) as against 7.06 c in 1903, while the London auctions also showed a similar decline, viz., 1*d.* as compared with 1½*d.* in the preceding year.*

The following figures show the quantities of quinine disposed of in Batavia by the Bandoeng quinine factory during the past three years:—

Year.	Quantity.	Average price per c.
	OZ.	d.
1902	821,608	11
1903	741,053	9½
1904	821,608	9½

NOTE.—The Dutch unit is calculated on half kilos., the one on 1 lb.; thus 6.5 cents equals an English unit of 1.18*d.*

ACETIC ANHYDRIDE: U.S. CUSTOMS DECISION, June 1, 1905.

The United States Circuit Court, June 1, 1905, decided that "acetic acid anhydrous" (acetic anhydride) which is not chemically an acid nor a base, is not chemically designated as such, is nevertheless dutiable as "acetic acid" under paragraph 1 of the tariff. The Court held that, while an article may be bought and sold by a specific name indicating a particular article, a group of such articles may be known in trade and commerce by a term which includes them all in a general group. Thus acetic acid is held to include acetic acid, anhydrous, and of various strengths. This decision reverses one by the Board of General Appraisers, which held it to be dutiable as a chemical compound at 10 per cent. *ad valorem* under paragraph 3.—R. W. M.

Patent List.

In these lists, [A.] means "Apphention for Patent," and C.S. "Complete Specification Accepted."

When a Complete Specification accompanies an Application, an is notified. The dates given are (i) in the case of Apphention for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals in which the Complete Specifications are advertised.

Complete Specifications thus advertised as accepted are open to opposition at the Patent Office immediately, and to opposition within two months of said date.

I. PLANT, APPARATUS, AND MACHINERY.

- 13,247. Lieberich. Filter.* June 27.
- 13,261. Harder. Furnaces for burning producer gas.* June 27.
- 13,355. Pearsall. Hydraulic Apparatus for raising or forcing liquids, or for compressing gases.* June 28.
- 13,492. Brewtman. Apparatus for cooling and heating liquids, fluids, vapours and the like. July 1.
- 13,603. Soc. Jules Jean et Cie., and Raverat. Process for recovering vapours of volatile solvents. [Fr. Appl., Sept. 1, 1904.]* July 1.
- 14,067 (1904). Kachl. Centrifugal separating apparatus. June 28.
- 14,238 (1904). Burdth. Apparatus for heating, cooling, and similar purposes. June 28.
- 17,854 (1904). Sharratt and Sharratt. Kilns and the like. July 5.
- 21,067 (1904). Macfarlane. Centrifugal machines. July 5.
- 1586 (1905). Hager. Indicator for receivers of distilling apparatus. July 5.
- 5147 (1905). Palau, Sibis, and Navarro. Apparatus for raising liquids. July 5.

II.—FUEL, GAS, AND LIGHT.

- 12,666. Lake, Deutsche Gasglühlicht-Akt.-Ges. (Auerges.). Mantles for use in incandescent lighting. June 19.
- 12,828. Moeller. Incandescent mantles. June 21.
- 13,129. Nield. Method of extracting water from peat, and making peat into briquettes for fuel. June 26.
- 13,263. Harder. See under I.
- 13,290. Syms. Gas producing apparatus for use with fuel of a bituminous nature. June 25.

- [A.] 13,304. Scott. Process for producing gas, and rendering it non-explosive. June 28.
- .. 13,495. Hall-Brown. Gas producer. July 1.
- [C.S.] 6959 (1904). Leys (Gen. Electric Co.). Process for electric incandescent lamps, and a process of manufacturing the same. June 28.
- .. 14,757 (1904). Thwaite. Method and apparatus for rendering iron blast furnace gases available for working gas motor engines. July 5.
- .. 14,917 (1904). Bayles. Fuel. July 5.
- .. 16,125 (1904). Electric Equipment and Securities, Ltd., and Kuzicka. Manufacture of electric incandescent bodies. July 5.
- .. 18,214 (1904). Hatton. Gas Producers. June 28.
- .. 6158 (1905). Bouchard-Bracey. Automatic apparatus for carburetting air and other gases. June 28.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 13,154. Spalteholz. Emulsions of tar oils, phenol, and similar products, crude mineral oils, and mineral oil residues. June 26.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 12,756. Newton (Bayer and Co.). Manufacture of new anthracene dyestuffs and intermediate products. June 20.
- .. 12,757. Newton (Bayer and Co.). Manufacture of a new anthracene derivative. June 20.
- .. 12,854. Johnson (Badische Anilin und Soda Fabrik). Production of indigo.* June 21.
- [C.S.] 20,527 (1904). Newton (Bayer and Co.). Manufacture of anthracene dyestuffs and their application in dyeing and printing. July 5.
- .. 11,205 (1905). Johnson (Badische Anilin und Soda Fabrik). Manufacture of azo colouring matters. June 28.

V.—PREPARING, BLEACHING, DYEING, PRINTING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 12,650. Knopf, and The Bremen Baumwollwerke C. Knopf & Co. Processes and apparatus for treating cotton seed hulls or other fibrous materials containing waste products. June 19.
- .. 12,956. Abel (Act. Ges. f. Anilinfabr). See under XVIII. A.
- .. 13,053. Ainley. Machines for washing and scouring textile fabrics. June 24.
- .. 13,356. Hardecastle. Method and machinery for treating fabrics, felts, yarns, slivers and the like with liquids, emulsions, gases, vapours, or dusts and the like. June 28.

- [A.] 13,580. Fell (Koendorfer). Process for oiling cotton and other vegetable fibres. July 1.
- [C.S.] 15,729 (1904). Roberts and Crossley. Method of and means for removing vegetable impurities from woollen rags, wool, and other animal fibres. July 5.
- .. 16,542 (1904). Mellor and Villy. Working or dressing textile fibres, especially silk or the like. June 28.
- .. 17,822 (1904). Carstanjen. Mordanting and loading silk and other textile fibres. June 28.
- .. 26,005 (1904). Smith. Apparatus for treating tubular fabrics with liquid or semi-liquid compositions. July 5.
- .. 28,003 (1904). Ollagnier. Treatment of cocoanut fibre and its application to the manufacture of brushes. June 28.

VI.—COLOURING WOOD, PAPER, LEATHER, ETC.

- [A.] 13,507. Wood. Wall-paper printing machines. July 1.
- [C.S.] 2013 (1905). Lafitte. Impregnation and colouration of timber. July 5.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 13,127. Hargreaves. Manufacture of salt. June 26.
- .. 13,447. Swayze. Process of making potassium salts. [U.S. Appl. July 5, 1904.]* June 29.
- [C.S.] 13,565 (1904). Castiglioni and Calastretti. Process for reducing sulphates of the alkaline earths and of the alkalis to sulphides, and for reducing metallic oxides to metals. June 28.
- .. 13,981 (1904). Behrens and Behrens. Process and apparatus for manufacturing carbonic acid. June 28.
- .. 23,515 (1904). Johnson (Badische Anilin und Soda Fabrik). Manufacture of stable hydrosulphites. July 5.
- .. 7634 (1905). Paramore. Art of treating and utilising chlorine gas. June 28.

VIII.—GLASS, POTTERY, AND ENAMELS.

- [C.S.] 18,437 (1904). Bottomley and Paget. Working of fused silica. July 5.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 12,698. Schuijft, Kunze and Overman. Process of preparing whitewash. June 23.
- .. 13,135. Brabänder and Koch. Process and apparatus for manufacturing artificial marble. June 26.
- [C.S.] 17,563 (1904). Wilkes. Separators and grinding mills used in the treatment of marl, clay, or like material. June 28.

- [C.S.] 18,376 (1904). Walton. Manufacture of floor- and wall coverings and the like, and apparatus therefor. June 28.
- .. 18,920 (1904). Lake (Matthey and Co.). Manufacture of electrical insulating or non-conducting compositions. July 5.
- .. 25,385 (1904). Wilkinson. Material for the pavements of roadways, &c. June 28.
- .. 8024 (1905). Lainé. Manufacture of composites for building and other purposes. July 5.

X.—METALLURGY.

- [A.] 12,652. Campbell. Treatment of chromiferous iron.* June 19.
- .. 12,868. Goldschmidt and Weber. The detinning of tinned plates. June 21.
- .. 12,869. Goldschmidt and Weber. The detinning of tinned plates. June 21.
- .. 12,870. Goldschmidt and Weber. The detinning of tinned plates. June 21.
- .. 13,141. Hoffmann. Manufacture of a substance to be used for the improvement of inferior steels. June 26.
- .. 13,242. Hobson and James. Gold alloys. June 26.
- .. 13,350. Langer. Apparatus for obtaining nickel from nickel carbonyl.* June 28.
- .. 13,351. Langer. Treating with carbonic oxide nickel ores or other material containing nickel and apparatus therefor.* June 25.
- .. 13,433. MacIvor and Fradd. Treatment of complex ores containing gold. June 29.
- [C.S.] 14,479 (1904). Krantschneider. Process for annealing and tempering metals and metallic products. July 5.
- .. 14,757 (1904). Thwaite. See under II.
- .. 16,517 (1904). Broadbent. Galvanisation of metals. June 28.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

- [A.] 12,852. Roxby. Electroplating. June 21.
- .. 12,853. Roxby. Electroplating aluminium. June 21.
- .. 13,427. Kitsee. Secondary batteries.* June 26.
- [C.S.] 18,920 (1904). Lake (Matthey and Co.). See under IX.

XII.—FATTY OILS, FATS, WAXES, AND SOAPS.

- [A.] 12,784. Perez y Garcia. Apparatus for liquefying oils and fats.* June 20.
- .. 12,907. Hatmaker. Process of mixing oils, fats and other substances in fluid or comminuted form with liquids. June 22.
- [C.S.] 13,983 (1904). Stockhausen. Compounds of sulphonated oils and fats and method of producing the same. June 28.

III. PIGMENTS, PAINTS; RESINS, VARNISHES; INDIA-RUBBER, Etc.

(A.)—PIGMENTS; PAINTS.

- [A.] 1,455. Alberti. Process for the preparation of lithopones.* June 29.

(B.)—RESINS, VARNISHES.

- [A.] 3,180. Thiemann. Process of utilising waste amber. [Ger. Appl., June 25, 1904.]* June 26.

(C.)—INDIA-RUBBER.

- [A.] 2,859. Von Stechow. Method of extracting pure raw rubber from rubber plants.* June 21.

- [U.S.] 14,588 (1904). Beadle and Steven. Method of food-stuffs for cattle and other animals. July 5.

(B.)—SANITATION; WATER PURIFICATION.

- [A.] 13,596. Venning and Lawrence. Process of purifying and softening water. July 1.
[U.S.] 17,994 (1904). Mather and Platt, Ltd., and Hopkinson. Methods of and means for purifying, softening and treating water. July 5.

(C.)—DISINFECTANTS.

- [A.] 13,034. Corbyn, Stacey and Co., Ltd., and Bell. Method of generating or evolving formaldehyde for disinfecting purposes.* June 23.

V. TANNING, LEATHER, GLUE, SIZE, Etc.

- [U.S.] 6,383 (1904). Loebell. Process for purifying crude viscine obtained from plants of the ilex class. July 5.

VI.—BREWING, WINES, SPIRITS, Etc.

- [A.] 4,480A (1904). Williamson. See under XVIII. A.
2,988. Connell. Evaporation and utilisation of potale or liquid distillery refuse and the like. June 23.
3,022. Petersen-Schepelern and Schwanenflügel. Preliminary treatment and ageing of spirits.* June 23.
3,186. Hunt. Treating or maturing spirits such as whiskey or brandy. June 26.
3,602. Soc. Jules Jean and Cie, and Raverat. Process for the recovery of vapours of alcohol pure, or mixed with air, gases, moisture or other volatile solvents. [Fr. Appl., July 25, 1904.]* July 1.
[A.] 4,382 (1904). Hunt. Maturing and improving the aroma of raw whiskey and other spirits. June 28.
[A.] 4,827 (1904). Hunt. Treatment of whiskey and other spirits. July 5.
28,619 (1904). Schrottky. Manufacture of beer. June 28.

VIII.—FOODS; SANITATION, WATER PURIFICATION; AND DISINFECTANTS.

(A.)—FOODS.

- [A.] 20,480A (1904). Williamson. Meat or malt extracts and preparations, aerated and other beverages or alimentary substances. June 22.
12,816. Evenden and Daw. Coffee preparations. June 21.
12,956. Abel (Act.-Ges. f. Anilinfabr.). Manufacture of silk fibroin peptone. June 22.
13,435. Davenport. Extract of fish. June 29.

XIX.—PAPER, PASTEBOARD, Etc.

- [A.] 12,805. Bayley. Process of treating paper to expedite ink drying. June 21.
.. 13,184. Trotman. The watermarking of paper. June 26.
[U.S.] 22,245 (1904). Didier. Manufacture and application of celluloid paste in imitation of white horn, buffalo horn, tortoiseshell, ivory, &c. June 28.
.. 9998 (1905). Fab. Prod. Chim. Flora. Process for directly converting cotton or cellulose into cellulose acetates. June 28.
.. 11,512 (1905). Béhal. Manufacture of celluloid. June 28.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

- [A.] 10,758A. Béhal. Manufacture of bornyl acetates.* June 24.
.. 10,758B. Béhal. Manufacture of camphors from bornyl acetates.* June 24.
.. 12,843. Newton (Bayer und Co.). Manufacture of new esters of aminoalcohols and of salts thereof. June 21.
.. 12,934. Wellcome, Jowett and Hann. Manufacture of a tropine derivative. June 22.
.. 13,347. Maschmeijer. Manufacture of substances with the odour of violets. [Ger. Appl., July 22, 1904.]* June 28.

COMMUNICATIONS

Members of communications read before the Society, or its Local Sections, are requested to take notice that Rule 43 of the Bye-laws the Society has the right of publication for three months of all such papers. The payment of this Bye-law renders papers liable to be used by the Publication Committee, or ordered to be printed for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry was held in Rome in April, 1906, during Easter week. Communications should be addressed to the President, Prof. E. Paternò, Via Panisperna, 89 Rome.

Changes of Address.

On notifying new addresses, members are requested to state them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is to be avoided as tending to create confusion. When making subscriptions, the use of the form attached to the publication helps in the verification of addresses, on the safe delivery of the Journal depends.

Annual General Meeting.

MONDAY, JULY 10TH, 1905.

After luncheon the members drove to Richmond, where they were entertained at a garden party by Sir Max and Lady Waechter, at their residence, "The Terrace House." During the afternoon Sir Max Waechter took a party of visitors over the picture galleries of Sir F. L. Cook, Bart., at Doughty House.

In the evening Dr. and Mrs. W. H. Nichols, Mr. and Mrs. A. Gordon Salomon, and the members of the London section held a reception in the gardens of the Royal Botanic Society, Regent's Park. About a thousand members attended the reception. The entertainments included an open-air performance of a selection from "A Midsummer Night's Dream."

TUESDAY, JULY 11TH, 1905.

The visitors and members proceeded from Westminster by steamer to Woolwich, where they were conducted over the Royal Arsenal by Sir H. F. Donaldson and members of his staff. They were then taken back by boat to Greenwich, where a fish luncheon was served at "The Ship." The afternoon was spent in visiting the Royal Observatory, under the guidance of Mr. Frank Dyson and his assistants.

At 9 p.m. the Lord Mayor (Sir John Pound, Bart.) and Lady Pound, supported by the Sheriffs in state, gave a reception at the Mansion House. Among those present were: Dr. Wm. H. Nichols and Mrs. Nichols, the Dean of Canterbury and Mrs. Wace, General Sir Hugh Gough, V.C., G.C.B., and Lady Gough, Sir Burdon Sanderson and Lady Sanderson, Dr. E. Divers, Sir William and Lady Ramsay, Sir Wm. and Lady Crookes, Sir Joseph and Miss Swan, Dr. C. F. Chandler and Mrs. Chandler, Prof. and Mrs. Armstrong, Prof. and Mrs. R. Meldola, Mr. Groves, Dr. W. H. Perkin, Dr. H. W. Wiley, Mr. and Mrs. A. Gordon Salomon, Mr. and Mrs. T. Tyrer, Mr. and Mrs. E. R. Nichols, Dr. L. Baekeland, Dr. V. Cobdientz, Dr. H. Schweitzer, Dr. Russell W. Moore, Mr. R. C. Woodcock, Prof. and Mrs. Mabery, Mr. T. J. Parker, Mr. Wm. A. Nash, Dr. W. A. Noyes, Prof. and Mrs. Pond, Mr. and Mrs. Voorhees, Mr. and Mrs. H. Howard, Mr. A. A. Claffin, Mr. and Mrs. Eugene Byrnes, Miss Mary Lynne, Mr. and Mrs. Krebs, Mr. C. E. Lager, Dr. C. Baskerville, Mr. V. G. Bloede and party, Dr. W. A. Converse, Mr. and Mrs. Miss Chadwick, Dr. Wm. Dreyfus, Dr. A. R. L. Dohme, Mr. P. Feibiger, Mr. M. L. Griffin, Mr. and Mrs. Hanna, Mr. Wm. F. Hoffman, Mr. C. M. Joyce, Prof. W. R. Lang, Mr. and Mrs. and Miss Lowe, Mr. and Mrs. Lieber, Mr. H. A. Metz, Mr. Max. Toch, Mr. H. S. Riederer, Mr. W. H. Van Winckel, Mr. and Mrs. Julian L. Baker, Mr. and Mrs. Spiller, Mr. and Miss Dunn, Mr. J. E. Riley and party, Mr. and Mrs. Gent, Mr. and Mrs. Lowson, Mr. and Miss Ratchliffe, Mr. Eustace Carey, Mr. Thos. Fairley, Dr. Clark, Mr. N. H. Martin and Miss Martin, Dr. G. H. Bailey, Mr. and Mrs. Hubner, Mr. W. Roscoe Hardwick, Mr. Samuel Hall and the Misses Hall, Mr. and Mrs. Miss Reid, Dr. and Mrs. Thorne, Prof. and Mrs. Miss Hodgkinson, Mr. and Mrs. Sydney Muspratt, Mr. and Mrs. Alfred Mond, Mr. and Mrs. Grant Hooper, Mr. and Mrs. Watson Smith, Dr. C. A. Keane, Mr. W. H. Hacking, Mr. and Mrs. Potter, Mr. and Miss Collett, Mrs. Lewkowitsch, Mr. and Mrs. Johnson, Mr. and Mrs. Butler, Mr. and Mrs. Bird, Mr. and Mrs. A. R. Ling, Mr. and Mrs. F. N. Sutton, Mr. and Mrs. David Perry, Dr. and Mrs. Dvorkovitch, Mr. and Mrs. Litch, Mr. and Mrs. Roberts, and many others.

WEDNESDAY, JULY 12TH, 1905.

A large party of members and guests left Paddington Station on Wednesday morning for Windsor. On arrival they were received by the Mayor, Sir William Sharley, in the Guildhall, where they were entertained to a "Champagne d'honneur." The party then visited the Castle. They were conducted over the buildings, including the State apartment, by Mr. Sandy, the engineer

to the Waterworks. The East Terrace was also visited by special permission of His Majesty.

Luncheon was served at "The White Hart Hotel," the Mayor being the principal guest.

THE ANNUAL DINNER.

In the evening, by the kind permission of the Prime Minister, the annual dinner was held at the Royal Smiths' Hall. Among those supporting the dinner were: The Rt. Hon. Lord Alverstone, Lord Chief Justice of England, the Very Rev. Dean Wace, Dean of Canterbury, Sir Wm. Huggins, O.M., Pres. R.S., the Hon. Lord Allerton, F.R.S., Sir Henry Primrose, Chairman of the Board of Inland Revenue, Dr. E. Divers, R.S., the Ven. Archdeacon Sinclair, the Hon. Mr. Buckley, the Hon. Mr. Justice N. Hall, Prof. R. F.R.S., President of the Chemical Society, Mr. Isaacs, K.C., M.P., Prof. Judd, F.R.S., Dr. C. F. C. Prof. Larmor and Sir A. Gokkie, Secretaries of the Royal Society, Sir W. Pridaux, Clerk to the Goldsmiths' Company, Prof. W. A. Tilden, F.R.S., Sir Boverton R. Sir J. W. Swan, F.R.S., Sir Thos. Wardle, Prof. F. Dr. T. E. Thorpe, C.B., F.R.S., Dr. W. H. Perkin, R.S., Mr. G. Bailby, Mr. E. K. Muspratt, Dr. Russell W. Dr. H. Schweitzer, Mr. R. C. Woodcock, Dr. V. C. Dr. H. W. Wiley, Mr. Henry Howard, Mr. Eustace Prof. W. R. Lang, Mr. T. Tyrer, Mr. E. J. Bevan, President of the Society of Public Analysts, Dr. C. Baskerville, Mr. Hall, Mr. A. Gordon Salomon, Mr. Julian L. Baker, Mr. C. Wightman, Mr. A. R. Ling, Mr. T. J. Parker, Prof. C. F. Mabery, Dr. L. Baekeland, Dr. J. T. Dunn, Mr. W. W. Butler, Prof. G. G. Henderson, Mr. David Perry, Prof. W. J. Pope, F.R.S., Mr. Julius Bauer, Mr. E. Grant Hooper, Dr. F. B. Power, Prof. R. R. Hodgkinson, Mr. N. H. Martin, Mr. T. Fairley, Mr. Hemingway, Mr. Walter F. Reid, Dr. W. S. Squibb, Mr. O. Guttman, Dr. K. E. Markel, Dr. A. C. Huntress, Dr. J. E. Teeple, Mr. A. A. Claffin, Dr. L. A. Dreyfus, Dr. M. Wallerstein, Mr. E. Remington Nichols, Mr. F. A. Nash, Prof. L. P. Kinnicutt, Dr. Max. Toch, Prof. G. G. Pond, Mr. H. S. Wellcome, Dr. W. A. Converse, Mr. E. Hatschek, Mr. F. E. Atteaux, Mr. H. A. Metz.

The PRESIDENT, with a graceful allusion to the birth of a Royal Prince which was announced that day, proposed the health of H.M. King Edward VII. and Queen Alexandra.

The Rt. Hon. Lord ALVERSTONE, Lord Chief Justice of England, next proposed the health of the President of the United States of America, and said he should like a note of sympathy from that assembly to go across the ocean to the President of the United States in respect of the great loss recently sustained by the American nation in the death of John Hay. Men of his abilities and high character in public life were not merely citizens of one country or one kingdom alone, they were the property of the civilised world; and when they died that broken down by the strain of great labours, which a life had come to its close, they could not but feel that the world of letters, of diplomacy, of honourable statesmanship was the poorer. He was, therefore, anxious not to propose the health of the President of the United States without sending to him a message of sympathy with him and his nation in that loss. The main motive which prompted thinking people at the present time to join with heartiness and unanimity in drinking to the health of such a man as the President of the United States was that though he had to face situations of the greatest difficulty, he had never failed in nerve or judgment, and had proved himself in every sense of the words a true Christian gentleman. He was called to his high position at a time of great stress and great distress. After the terrible death of President McKinley, he was called upon to assume, at a moment's notice, the position of President of the United States. After more than two years of Presidential work, he had been again re-elected, with most remarkable expressions of opinion, at a late election, when his term of office was renewed. Of course, every man, however well-meaning and however able, made mistakes, and nobody was so foolish as to suppose the contrary. He might remind them of what would

merican ambassador, the late Mr. Phelps, to a assembly of Englishmen, that he knew he made mistakes, but he was comforted by the reflection that a man who never made mistakes never made anything. He did not suggest that no mistakes had been made; but he might venture to say that Roosevelt had shown that he brought to the fore of the day strong and vigorous opinions, which he did not hesitate to express; and which, whether they were right or wrong, carried with them the conviction that he was the opinions of an honest man striving to do the best for his people and the best for the civilised world. Roosevelt had, taken, even during his first office, he had called the attention of the civilised world to the schemes of peace; and his aspirations for general peace were set out in marked relief by his invitation given to the world, to again meet at The Hague to consult on the peace of the world could be further promoted. He also referred to the action the President of the United States had just taken in recognising that, owing to his independent position, it was in his power to take a position which no crowned head in Europe could possibly do. He had not hesitated to take steps to put an end to the terrible war which was causing so much misery in the eastern part of the world. He felt that King Edward VII. and President Roosevelt during the last three years, more for the peace of the civilised world than any other two men. He asked them to drink the toast of the President of the United States with the hope that the remainder of his office would be as successful as its commencement.

THE PRESIDENT then announced that the following would be sent to President Roosevelt: "At the request of the Society of Chemical Industry, attended by British and American Members, your health was cordially proposed by the Lord Chief Justice of England and enthusiastically received. We send respectful greetings and sympathy with you and your people in the name of Mr. Hay."

DR. GORDON SALAMON then announced that he had received congratulatory telegrams from Dr. Hart and Dr. Messel.

C. F. CHANDLER said he had been selected to give the toast of "The Houses of Parliament" because, as far as he knew, there was no person present who knew less about the Houses of Parliament. He had had occasion to visit either House of Parliament, but he had a dim recollection of having read that Guy de Maupassant once tried to "toast" the Houses of Parliament, and he was to grief; and he had also read about the Great War having come into conflict with the House of Commons; but his personal knowledge was extremely limited. He first began to learn something with regard to the practical work of the Houses of Parliament when he had occasion to provide himself with those wonderful books. Nearly 40 years ago, when he was studying the history of water, he found it necessary to consult the Reports issued by the Rivers Pollution Commission, and there he found the most valuable information—in the language of the most useful information from those Reports than from anything he found either in the language of the French. After this experience he had a rule ever afterwards when discussing any matter relating to the public welfare and requiring any knowledge of chemistry or physics, to look at the Blue Books. He had studied amongst others those published by the Rivers Pollution Commission, and he always obtained from them information which he could not obtain from any other source. Thus he came to admire the system of the Houses of Parliament. When any new subject came up, they did not sit still and allow interested persons to come and press their views; but they sent for the most distinguished men in the kingdom and questioned them in a simple straightforward manner, and thus

obtained from them the best knowledge the world possessed on the particular subject before the Committee. On one occasion he came into personal contact with one of these Committees, having appeared some years ago before the Committee dealing with the subject of petroleum. He had previously been before a Committee of the United States Senate on oleomargarine, and he remembered saying to the Chairman of that Committee, one of his own pupils, that the legislation which resulted was absolutely contrary to the advice he had given them; and the manufacture of that eminently nutritious and satisfactory form of food was put under a ban in the United States. The State of New York, which had never spent one cent for Chemical Education, once spent 70,000 dollars a year in preventing people eating oleomargarine. On the particular occasion when he came before the Committee of Parliament he was very deeply impressed; he thought it was the most dignified session he had ever attended. The question was one as to raising the flash-point of petroleum as required by law, and in which the interests of the American oil producers and Scotch oil refiners were in antagonism. He was much struck with the impartial character of all the remarks that were made before that Committee; there did not seem to be any partisanship or any bias on the part of any member; and he carried away with him a deep feeling of the dignity and fair-mindedness of that Parliamentary Committee. Speaking broadly, the Houses of Parliament represented to his mind the ideal of taxation coupled with representation. Taxation without representation was the cause of the breach between the American Colonies and the Mother country. In England they had almost universal suffrage. Unfortunately, in America they had complete universal suffrage. When the subject of suffrage came up in the Constitutional Convention it was proposed that there should be a property qualification, and there was a strong feeling in favour of such a provision. Benjamin Franklin suggested that it would be eminently proper to permit it, but there would be some difficulty in carrying it out in detail. It seemed to him that the Houses of Parliament represented Government for the people by the people; they had developed by the publicity of their discussions and the wisdom of their deliberations the most perfect system of civil government, a system which gave justice and equity before the law to all the citizens of the British Dominions. Without making any invidious comparisons between the Government of his own country and that of Great Britain he could not say that there was any country in the world which had a fairer or more just system of government than that which had been secured by the deliberations of the Houses of Parliament. He coupled with the toast the names of Lord Allerton and Mr. Rufus Isaacs, M.P.

LORD ALLESTON, in responding for the House of Lords, said that he had listened with great interest to the speech of Prof. Chandler, and he was much gratified to learn the good impression which had been made upon his mind by his experience of the Houses of Parliament. Englishmen were proud of their Houses of Parliament and of the power which lay behind them; and he hoped he might be allowed to claim with becoming modesty for the House of Lords that they never showed themselves unwilling to take their fair share of the work of the nation, not only in their own House but in work outside in the field, if they were called upon; and in many positions of distinction both in Commerce and, as he was going to say, in Chemistry, there might be found distinguished members of the House of Lords. That House took just as much interest in all that concerned the welfare of the Empire and the nation at large as did the House of Commons; their objects were the same; they might strive a little differently in detail, but their object was the welfare of the people and the country to which they belonged. He was himself a Member of the Society of Chemical Industry, and he read their proceedings with great interest. He doubted whether one could find the same number of members in any society or profession of men upon whom so largely depended the progress of commerce and manufactures as one would find in this Society. It was because he felt the great importance of it, apart from those questions upon which

the Lord Chief Justice had touched, that he felt it was of the greatest possible good to this country that they had had visits from men so distinguished as those who constituted the Society; and he hoped such reciprocal visits might tend to make for progress in the department in which they were specially interested, because that department was one which made for the progress and welfare of the commerce of the world at large.

Mr. RUFUS ISAACS, K.C., M.P., said he should like to add his humble tribute to what had fallen so well from Lord Alton in response to what Prof. Chandler had said, that no one who was a member of either House of Parliament or who cherished the traditions of those Houses could have heard unmoved the high testimony by Prof. Chandler to the work of those Houses. The work, the result of which was collected in the Blue Books, was work which was quietly done, and of which the public heard little. Prof. Chandler had told them how valuable he had found them, and had given thereby great encouragement to those who sat on Committees and did their duty, having before them undoubtedly the testimony of the highest in the land, and being thus able to pass a judicial opinion upon the subjects brought before them and upon which they had practically to decide.

Dr. E. DIVERS said the Society of Chemical Industry needed no words at the annual dinner of its members and their friends in support of the toast of its prosperity. That toast would that evening and at many annual dinners to come be welcomed with enthusiasm, whatever might be the brevity with which it was brought forward. During the past Session the prosperity of the Society had been satisfactory to those who did not expect too much. There had been evidence that there was much more to be done, but this was no reproach to the action of the Society during the past Session, but rather evidence of the progress that had been made which had brought about its awakening to the fact that so much remained to be done. At the present time the Society numbered some 4326 members, and there was every promise that at the end of the next year there would be a much larger number. In the United States, the Society had added a New England Section; and in England it had revived the Birmingham Section under most favourable auspices. It had taken part, indirectly through some of its members, in bringing about legislation favourable to Chemical Industries; and, as evidence of the power which it had over its members, he need only point to that meeting, which had drawn about a hundred of its members across the Atlantic to take part in its celebration. During the Session its numerous Sections had brought together large bodies of members to take part in the proceedings, and to arouse in them, as he hoped, a common and united interest in Chemical Industries in general, rather than in their own particular subjects only. Their Journal, published fortnightly, had given them a great number of papers, many of them of particular value in technology and even in pure science. One other point not to be overlooked was that the affairs of the Society had been carried on in such a way that their expenditure had not exceeded their revenue. That account of the Society might seem a very bald one after the splendid examples of oratory they had heard from previous speakers; but, after all, the Society was always with them and he found it very difficult to speak in any special terms about it, because they all knew about it, heartily appreciated it, and were deeply interested in its welfare. He had the supreme satisfaction of inviting their President to respond to that toast. Eminently successful in chemical technology as an electro-metallurgist, Dr. Nichols had carried out the business of the Society during his Presidentship with remarkable success: he had been for nearly the whole of that period separated from headquarters by the broad Atlantic, yet he had by active correspondence made his opinions strongly felt, and the advice which he so frequently gave had received the hearty concurrence of the Council and those who had to work with him and under his directions. His address on Monday last was fraught, not only with great advantage to the Society, but to chemical technology all over the world; it was a remarkable address, and he thought he

might say it would greatly add to the benefits Dr. Nichols had conferred upon them if he would, on his return, some time to the expansion of that address into a paper on the subject of the management and organisation of chemical works. He was quite sure that such a paper would be received with very great approval, would have a very wide circulation, and would add greatly to the development of manufacturing interests both in Britain and in America. On behalf of the Society he took upon himself to thank the President most cordially for the services he had rendered during his year of office.

The PRESIDENT said that he could hardly express the singular sensations which he had experienced in sitting in that distinguished company in that magnificent hall. He was the President of one of the young Societies, for they were less than a quarter of a century old, and what was a quarter of a century in a century which reckoned by almost milleniums? He was to be their President if only for a little while longer. The Society was one which had a great deal to be proud of. In the first place, they were proud of being in that magnificent hall of the old Goldsmiths', where they were proud of their distinguished guests, to whom he had addressed them, but many of whom had the opportunity to do so; they were proud of their Presidents (he would say nothing about the past President). The other evening, at a somewhat less formal gathering, more than twelve of them sat together at one table, he thought, than had ever been gathered together in one room. They were proud of what they had done for the Society, and still more proud of what they had done for the public: they were proud of their work, though he would not say much about that because he was one of the number: they were proud of their Education Committee. He had had the good fortune to attend for the first time the other day a meeting of the Committee, and he was astonished to see the amount of work done, done freely and gladly, by that magisterial body of men; and in consequence of their work, the work of members who contributed articles, the work of the Journal, which he might safely say was the best Journal on the subject of Chemistry and Chemical Industry which was published in the world. He was proud of all those things, but he would not dilate upon them, as he had had his innings last Monday, and would not inflict another speech upon them. He would, however, say that he was sure the Society was one of its New York Section; the name was somewhat of a misnomer, as that Section included a very large number of the United States, almost, in fact, the City of New York. It numbered more than 1400 members, or nearly a third of the total membership. He mentioned that because the great success of that section was due, usually the case, to a very few gentlemen. He had heard that one of them, Dr. Love, had sent a cable message last night. Dr. Love was a gentleman who was present at the birth of the Society; and had been one of the most active members in the New York Section. He had with them that evening Mr. Parker, who had done a great deal of service, and Dr. Chandler himself, who did not spend all his time reading Blue Books and delivering lectures, but found time for other work which he thought was in its way just as useful. Without mentioning too many names, the New York Section owed a great deal to two gentlemen who were with them that evening and whom the New York Section desired at that time to especially honour. He referred in the first place to the genial gentleman who had for so long conducted the *seances* of the *Deutscher Chemiker*, which met at the conclusion of the business of the New York Section, and which did noble scientific work in the consumption of large quantities of time. It was not, of course, in that capacity that he, Dr. Hugo Schweitzer, but because without his help he did not know what that Section would have been. It certainly would not have been what it was to-day, and what it promised to be in the future. But, as a slight token of the appreciation of many hundreds of workers and members, he had the honour of presenting to him that evening, on behalf of the New York Section, a beautiful gold medal, appropriate to that hall, bearing

ription, "Presented to Dr. Hugo Schweitzer by her members of the New York Section of the of Chemical Industry, as a token of their high and appreciation of his long and faithful services, Secretary of the Section, July, 1905." The other similar if not exactly like the first, having on the open of the scribe, and the other having a cornucopia money rolling out of it, not a shilling of which it, with a similar inscription of the same loving was for Mr. R. C. Woodcock, who all through the life Section had been its honoured and efficient er. There was one more thing they had to be for and to be proud of, and that was the glorious which it was theirs to follow and uphold. Might ways be true to it, and proud of it! To be a was to be in almost the highest position, in his it, to which a man could attain.

OVERTON REDWOOD, in proposing "The Learned," said he had noticed that their American brothers, of making themselves better acquainted with institutions than they were themselves, and he d to think that that accounted for the shade of resignation which he observed to pass momentarily the habitually cheerful countenance of the it when he rose to propose this toast. No doubt hols had learnt that there were in Great Britain an 1000 of these societies to which he was expected when proposing that toast, and that a carefully ed record of the proceedings of those societies y filled a volume of some 300 pages. He must hat the labours, largely unselfish and unseen, of army of workers in the limitless field covered by ed societies, was a fruitful and inspiring theme. must hasten to reassure Dr. Nichols by telling him was far from his intention to attempt to deal neatively with so great a subject. He would, r, crave indulgence for reminding them that in of antiquity as well as in regard to distinguished of work done, the United States could claim much own learned societies. So far back as 1743 Dr. issued a proposal for the promotion of useful ge amongst the British plantations, and in the g year the American Philosophical Society was in Philadelphia, with Dr. Franklin as Secretary. ocity, of which, thanks to the support of Dr. er, he had had the privilege of being an honorary r for many years, was the first society to be l in America for the pursuit of philosophical gation in its broadest sense; and it was also well known that the Smithsonian Institution, as established by Act of Congress in 1838, though society in the strict sense of the term, ranked as the most important and most useful of scientific That institution was founded by Hugh Smithson, of a Duke of Northumberland. So that the had something to do with the inception and istory of these societies in the United States. But rather of British societies that he had to speak, and, ce, first in antiquity and dignity came the Royal ty, of London. It was, therefore, with peculiar pride e alluded to the circumstance that they were ex- ally honoured that evening by the presence of the ous and revered President of that Society, Sir n Huggins. They were also very fortunate to ith them Prof. Joseph Larmor and Sir Archibald , Secretaries of that Society; and they had also ntatives of other learned societies, including the ent of the Chemical Society. The work done by and other societies was well known to all. The ed Societies had mainly come into existence during neteenth century, to meet the need of organisation ystematisation of science, and for the provision of a common ground where the various workers meet to discuss results. They played, undoubtedly, y important part in facilitating the interchange as, and stimulating by example and competitive to renewed effort in probing the secrets of Nature, generally promoting the advancement of knowledge. gged to couple with the toast the name of Sir William ns.

Sir Wm. HUGGINS said that in the name of Science and as the representative of the Royal Society, the oldest chartered scientific society in this country, and the venerable, but still young, mother of many distinguished daughter societies, he begged to tender thanks for the cordiality with which this toast had been received. In speaking for Science, he was under some disadvantages as compared with those who represented Commerce, Politics, and Fiscal Policies, for he could not appeal to one of the strongest of human passions—party feeling. Science, above all things, was the harbinger of unity, peace and goodwill amongst all men; it recognised no territorial limits; it knew nothing of language or race; it was equally at home in every country, and the fatherland of Science was as wide as the earth itself. The scientific societies in the past had done not a little towards unity by electing colonial and foreign members, and bringing together men who dwelt in all parts of the earth, whether as inhabiting the British Dominions across the seas or belonging to other nations. But it had been left for the Society of Chemical Industry to take another and a great step forward towards the realisation of the brotherhood of Science, by opening its doors to men of every country and every race. While still a British Society, its membership included the English-speaking peoples of the earth. Amongst those sitting at the table that evening they had not only their brethren from Canada but their other brothers, only once removed and quite as dear to them, from the United States. Truly, such a meeting as that might be taken as some advance towards that federation of the world, which was the cherished dream of the poet and of the man of Science. That Society might be said to have thrown a bridge across the Atlantic, over which their friends of the other hemisphere had come to feast with them that night, when, for the second time, an American presided over the Society. The Royal Society welcomed this manifestation of the brotherhood of Science; and marked its appreciation of the great importance of such international exchanges of courtesy and friendship and of scientific opinion by the new departure of a reception to those and their friends who had come across the seas, which would be held on the following evening. In industrial production, in competitive ownership of parts of the earth, and in the rival ruling of the seas, the pre-eminence of one country, or of one race, meant necessarily more or less the subjection of other countries or races—the gain of one nation was the loss of another; but the victories of Science stood alone in that there was no enemy, no one was defeated and the conquests of Science were pure gain and enriched the whole human race. The increased power over Nature secured by the work of Faraday, or of Edison, or of Rutherford, did not give exclusive advantage respectively to Great Britain, to the United States or to Canada, but to all three equally alike—it enriched mankind. Any cheque for discovery, drawn with the pen of experiment, by any man, rich or poor, free or bond, Greek or Barbarian, on the Bank of Nature, would be honoured in full without the impoverishment of any other man. Like the widow's cruse of oil and barrel of meal, the stores of Nature were not diminished by what was taken from them. The forecast of the present century was not doubtful. It needed not the skill of the Augur to determine from the signs of the heavens or from the flight of birds to forecast that man's progress would be in direct proportion to his increased power of dominion over the forces of Nature. The scientific societies had, in common with the Royal Society, the object of improving natural knowledge; and it was only by the increase of such knowledge that man could hope to supply all his needs, his increasing needs, from the unlimited stores of Nature. It was surely unnecessary for him in that assembly to say how completely the future condition of mankind, in its intellectual composition as well as in its material resources, depended upon the growth and activity of the scientific societies.

Mr. GORDON SALAMON, in proposing the toast of "The Guests," said it was unnecessary to speak at any length in its favour, at least with regard to that portion of it which referred to the welcome they had sought to give

to their guests from across the Atlantic. They had already been formally greeted, and he trusted that since they had been in London they had found that their welcome was true and sincere, and that they would go back knowing that they were regarded as essential to the continued prosperity of the Society. He could only say, on behalf of the Society, that their American and Canadian friends were not only welcome, but he was happy to think there was no feeling of rivalry between them. They were all possessed of one spirit, namely, to promote the good of the Society throughout the world, and, further, to promote the continuance of that feeling of kinship which united them to-day. With regard to the other guests present, they greatly appreciated their coming amongst them and giving their support to the President. Finally, in the name of the Society, he must express their most grateful thanks to the Prime Warden and Court and Sir Walter Pridcaux and the Goldsmiths' Company for permitting them to use that most beautiful and historic hall for their annual dinner. In giving that toast he could not refer to all the guests in detail, but he would ask two gentlemen to respond—one who had received the Victoria Cross of that Society that evening, Dr. Hugo Schweitzer, and also Dr. Wiley.

Dr. HUGO SCHWEITZER said before replying to the toast it was only proper that he should refer to the great and unexpected honour which had been bestowed on himself and his esteemed friend, Mr. Woodcock. He was so surprised and touched by it that he could not find words in which to express his gratitude. They had done nothing but what they considered to be their duty to their fellow chemists, and if they thought it just to reward them so very highly, they could only, of course, accept their gift with great gratitude. In one respect, his selection to respond to the toast had been a most excellent one, for it was not within the power of any orator to express gratitude for the limitless hospitality which had been accorded them—it took heart and sentiment to do that, and in those respects he yielded to none. He thanked them from the bottom of his heart for all the pleasures they had enjoyed, and also for all they were going to enjoy; and he thanked them especially for the American members, whom they seemed to insist on spoiling as a loving mother spoils her only child. His selection was probably due to the fact that he had been connected actively with the first over-sea Section, and also to the fact that in his career he represented the internationality of the Society perhaps better than a great many others. He was a German by birth and an American by selection, and he had been closely attached in his life work to the interests and the members of that Society. Dr. Nichols had told them a few of the things of which they had reason to boast; but he had left out a few things to which he might now refer. England had developed the gentleman. That word had to be introduced into the languages of all nations, for none were conscious of its lack until they met that perfect type, the English gentleman. England had given them their beloved profession, and it had also given them healthy recreation. The sons of Great Britain were the first to recognise the truth of the adage that, "All work and no play makes Jack a dull boy"; they had given them such healthy sports as lawn tennis, football, cricket, yachting, hunting and that more strenuous game which was played according to rules formulated by the Marquess of Queensberry. This great country was the mother of chemical industries; here the manufacture of acids, alkalis and the coal tar colours had been developed; it was also here that the Bessemer process had been discovered. England had produced Faraday, Humphry Davy and Dalton, and he knew not how many more, and there still lived here to-day Perkin, Thorpe, Muspratt, Mond and Ramsay. Americans were happy to be connected with England, not only by the close ties of international science, but they were proud to be connected with it by a common language and a common Teutonic origin. In conclusion, he would ask them all to drink to their hosts, and to those gentlemen who had planned and arranged that wonderful feast.

Dr. H. W. WILEY said it was difficult to say anything further in response to this toast, but it was pleasant to

even attempt to give some voice to the feelings of his countrymen with regard to the way they had been received in England. It had been said that "Gratitude is a lively expectation of favours to come," and the gathering was happily inserted in between the immense amount of favours already received and those to which they were still looking forward. Every American thought it was his privilege to have the chance of making a speech, and were it not for its bad reputation, he could help wishing to be a Hydra, because it would take heads, each one furnished with a silver tongue, to all that should be said on such an occasion as this. What was the secret of this bond of amity of the peoples? He did not believe that the spirit of it was entirely or even very much due to kinship, but some of the keenest quarrels he had ever known occurred in the domestic circle. He thought it was because two peoples were inspired by the same spirit, the same love of freedom and the same desire for justice should be meted out to every man. He believed the science of chemistry played no mean part in bringing them together; the free development of commerce and the open door were what they both fought for with perhaps a preference in their own favour. He loved the English because they were a strong and vigorous race, having the stamina and ability to carry out what they undertook; that was because they were a free nation. A great friend of his at Yale considered that people ate three times too much, but it was well-fed nations that came to the front, and those who wrote on dietetics and said that people ate too much generally did so after having a good meal, sitting in an easy chair, and smoking a good cigar. It was said that during the great Civil War, a deputation waited on President Lincoln and asked him to resign. General Grant from the Army of Tennessee, who had just won a great battle, because he drank whisky. President Lincoln paid great attention to what was said, and then asked if the deputation could tell him the of whisky which General Grant used, because he had he should like to send some to the other generals. It was the spirit that animated them which led to it. As long as they had the same spirit and loved liberty and justice, they would be drawn nearer and nearer together, though there was no separation between them now as far as he could see.

Sir JOSEPH SWAN then proposed "The Health of the President," which the latter briefly acknowledged.

A "Ladies Dinner" was also held on Wednesday evening, at the Café Royal, Regent Street, attended by about one hundred and twenty; Sir Wm. Ramsay, K.C.B., F.R.S., presiding. After the toasts of the King, Queen, and Royal Family, and the President of the United States had been duly honoured, Mrs. A. Gordon Salamon proposed "Our Lady Gits," which was most cordially received, and was responded to by Mrs. Wm. H. Nichols. "Applied Chemistry" given by Mrs. Lewkowitsch, and responded to by William Ramsay. Dr. M. O. Forster, F.R.S., proposed the health of the Chairman.

London Section.

Meeting held at Burlington House, on Monday, July 31st, 1905.

MR. A. GORDON SALAMON IN THE CHAIR.

THE MANUFACTURE AND USE OF ART PAPERS.

BY R. W. SINDALL.

These special papers are now made in large quantities to supply the demand for a paper having a smooth surface suitable for the printing of half-tone blocks. The clear-

il, and the sharpness of outline required in an action produced by process printing cannot be obtained on ordinary paper, however highly glazed and since the surface is not sufficiently smooth, but application of a mineral coating an enamelled is obtained which is perfectly even and level, capable of taking an extremely high polish. The very employed in the production of these papers is complicated, and the operation appears to be quite though, as a matter of fact, the difficulties connected with the manufacture and use of "Art" papers are

coating applied to the surface of the paper varies position according to the quality of the work, the consisting of some inert mineral substance such as clay, blanc fixe, or enamel, mixed with the quantity of an adhesive-like glue or casein. For mass papers in which good colour and extra finish desired qualities, blanc fixe and satin white are in conjunction with glue, commoner qualities being with china clay.

The machine for the manufacture of coated paper is of three parts. The first is the coating section the second is the drying apparatus, and the third appliance for reeling up the paper.

The reel of paper to be coated is placed in any convenient manner upon a shaft at the back of the coating tank, which is a large drum about 4 ft. diameter, and wide. The paper is led round under the drum and over the top, and as it passes over it is brought into contact with a short endless felt, which transfers the mixture to the paper. The mixture is constantly fed into a narrow copper trough fixed to the front machine, and this is maintained at a suitable temperature. A copper roll rotating in the trough brings a steady stream of the liquid on to the felt, and the act of coating transferred to the paper is regulated by reeling rolls. The thorough adhesion of the enamel is even distribution over the surface of the paper is it about by a series of brushes, usually seven in number, which operate on the top of the drum and brush enamel well into the paper. Some of these brushes are while the others, actuated by small cranks, move from side to side. The last two or three brushes fitted with soft bristles to ensure an even surface on brush "marks." The wet-coated paper is then taken over to the drying apparatus, which consists of two parallel rails fixed 8 or 9 ft. above the floor, upon which slowly travel endless chains carrying a series of rollers at regular intervals. By an ingenious device the paper is caught on the sticks, taken up a sloping incline until it reaches the rails, and then it falls into a series of festoons or loops, the whole of which are moved forward upon the rails. The drying is hastened by the use of a current of air heated to about 85° F. If the paper is not long enough, a turntable is provided which is the festoons to describe a semi-circle at the end of the run, bringing the paper along a second set of rails to any required distance. This device has the additional advantage of bringing the finished paper directly under the observation of the man in charge of the coating machine. The dried paper is reeled up by a special reeling machine.

On the opposite side of the paper is coated in a similar manner, the reel from the first operation being passed over the machine a second time.

Refinements have recently been introduced for coating the sides of the paper at one operation, but the results are not altogether satisfactory for high-class work.

When coated the paper has a dull surface, and a high gloss is then given to it by means of the super-calender, in which process the paper is cut to any required shape and dimensions.

MATERIALS USED.

For ordinary art papers the proportions of enamel and glue are 100 lb. of mineral to 18 to 25 lb. of glue. These proportions are mixed with water to give a solution of glue. The glue is soaked in cold water for 24 hours, then gently heated in a copper steam jacketed pan in which mineral is worked up into a creamy paste with water

and thoroughly mixed with the glue. Ammonia is added to the mixture for the production of coloured or tinted papers.

Of recent years casein has been largely employed as a substitute for glue. About 18 to 20 lb. of casein are required for 100 lb. of mineral, and, since it is insoluble in water, borax or ammonia is necessary as a solvent. The casein is stirred into cold water and gently heated to about 100° F., and after the addition of 1½ lb. of borax, still further heated to 140° F. Casein sometimes imparts an unpleasant smell to the paper, if it has been dissolved any length of time, but the addition of a little formalin is usually sufficient to remove defects of this kind.

The decomposition of casein in solution, even to a slight extent, diminishes its adhesive properties, and as a matter of common experience, a coating mixture prepared from casein which stands over from a Saturday to the Monday following is frequently rendered foul and useless. Inattention to details of this kind is a fruitful source of trouble, which only appears at the printing office, when it is then impossible to trace back the primary offender. The manufacturers of art papers are frequently puzzled to explain defects for which there does not appear to be any adequate cause, and this question of the alteration of adhesive properties in the prepared coating mixture is one of them. The alteration may be traced in some instances to comparatively simple causes, of which I venture to illustrate one.

When ordinary glue and moist satin white are the ingredients for a mixing, it is evident that the ratio of dry glue to dry mineral can only remain constant when the raw materials are of uniform and constant composition. If the moist enamel contains a lower percentage of water than some accepted standard, then the amount of glue must be varied to meet it. But the manufacturer does not always test the mixture, and we may, therefore, have variations of a greater or lesser degree.

The explanation of the differences, which may occur with the printing on successive deliveries of art paper to the printer from the paper-maker, may appear almost too simple, but it is a matter of common experience to the consulting chemist, that simple causes are those which come to be frequently overlooked by manufacturers. It is only by specific instances of this kind that we indicate the possibility of arriving at a satisfactory solution of the difficulties encountered in every commercial industry.

QUALITIES OF ART PAPER.

The finished art paper presents many different physical qualities to those found in the body paper. The weight and bulk are greatly increased by the additional mineral matter added, the increase being determined by the amount of finish necessary. For heavy art papers the extra weight is generally 10 to 12 lb. per ream of 480 sheets, and the thickness is increased 12 to 15 per cent., so that books made from such papers are very heavy to handle, and are also extremely bulky.

The unpleasantness and fatigue caused by the reflection of light from the surface of high-glazed art papers is a matter of common experience, and the use of art paper for ordinary letterpress work cannot be too strongly condemned. The use of poor paper, closely printed letterpress, unseitable surface, outrageous colours, and other defects in relation to paper generally, are fruitful sources of injury to the eyes and brains of readers, perhaps more so than most people are aware. A close investigation into this subject would amply repay attention.

THE "BODY" PAPER.

It is clear from these descriptions of the methods used for coating paper, and the reasons given for the necessity of such a coating in the production of a purely artificial surface, that the composition and quality of the "body" paper is not a matter of very great importance. To a large extent this is quite true, but in the better qualities of art papers the nature of the "body" must be studied. Flexibility and resistance to the frequent turning over of the leaves of a book can only be ensured by the use of suitable material as the constituent of the body paper. Hence esparto is found to be preeminently suitable for

the purpose, and when mixed with chemical wood-pulp in varying proportions gives results which are satisfactory.

Esparto is a grass found in Spain and Algeria, having the following composition:—

(Muller)	Spanish.	African.
Cellulose	48.25	45.80
Fat and wax	2.07	2.62
Aqueous extract	10.19	9.81
Precious matter	26.39	29.30
Water	9.38	8.80
Ash	6.72	3.67

It is imported into this country in huge bales which on arrival at the mill are opened, freed from dust by special winnowing machinery, and the esparto thus cleaned. The grass is loaded into stationary digesters and boiled for six to seven hours with 15 to 20 per cent. of its weight of caustic soda at a pressure of about 60 lb. The boiled pulp is then thoroughly washed and bleached with chloride of lime solution, the yield of bleached cellulose being between 45 and 50 per cent.

Esparto fibre when examined under the microscope has many characteristic features which render the identification of the particular form of cellulose an easy matter. Fibres of the fibro-vascular bundles are slender, short, needle pointed fibres, whilst the presence of certain pear-shaped vessels determines the esparto with ease.

The wood pulp which forms one of the constituents of ordinary magazine papers is prepared chiefly by the "sulphite" process. The logs of wood having been thoroughly freed from the outer bark, and dirt, are chipped up into small flakes, which are thrown into huge steel digesters 50 ft. high, and 15 ft. internal diameter, lined with acid-resisting brick or cement, capable of holding 20 tons of wood at one charge. A solution of bisulphite of lime (prepared by passing the fumes of burning sulphur into towers containing blocks of limestone moistened with water) is run into the digester, which is then closed, and its contents heated by steam.

The wood is boiled for eight or nine hours at a pressure of 80 lb. and thereby reduced to a pulpy mass which can be washed and thoroughly cleansed from the soluble by-products. A yield of 50 per cent. of cellulose is obtained.

PREPARED PULP.

It may be noted in passing that the primary action of the bisulphite process in the digester is one of hydrolysis, with subsequent formation of sulphonated products, and may be briefly stated thus:—

Just as sugar is inverted by the hydrolytic action of water, and to a far greater extent by a mineral acid, so the cellulose compounds, and even to a more or less degree the normal cellulose itself are hydrolysed when treated with sulphurous acid.

The use of alkaline sulphites with sulphurous acid is preferable to that of sulphurous acid alone, inasmuch as, though the action of the latter upon the organic residues, as compared with sulphuric or hydrochloric acids for example, is greatly modified (perhaps, owing to its reducing action), nevertheless degradation does take place, resulting in the formation of tarry products which permeate the whole fibre substance and thus consumes a much larger quantity of bleach than would be required for the same wood using bisulphite of lime.

Another advantage in the use of the latter method as compared with the soda process for resolving the wood is, that the phenolic colouring matters in the cellulose compounds produce soluble colourless derivatives by reduction, and hence cause the fibre to be of a better colour.

With cheap art papers, the materials used for the "body" are of greatly inferior quality, and "mechanical" wood pulp, as it is called, often forms a large proportion of the paper. In the entire absence of any standards of quality, it is not surprising to find that many high class illustrations of considerable value, even if only of a temporary character, are printed on papers of very low quality.

It is necessary that the body paper should be carefully made, its surface being fairly even, yet not too smooth. The marks of the machine wire should not be too pronounced, since irregularities on the surface of the paper due to these marks cannot be completely obliterated if the coating subsequently put on the paper is thin.

Another important feature in the body paper is the extent of the sizing. The papers are treated with size, and the conditions for proper coating require uniformly sized body paper in order that the ratio of glue to enamel on the surface may remain constant.

The irregularity in printing results may sometimes be traced to uneven sizing of the body paper, so that during the coating operation, the glue of the coating mixture tends to soak more readily into the body paper a time than another, thereby disturbing the composition of the artificial surface.

In cases where the ratio of glue to enamel is already barely sufficient to resist the pulling or lifting of the printer's ink, any slight alteration of this kind will give rise to serious trouble.

It must not be forgotten that there are many conditions which affect the final results. The influences may be cumulative, or, on the other hand, they may neutralise one another, so that the figures which analysis may give as representing the percentages of certain ingredients cannot always afford conclusive evidence. The following is an illustration of a simple case of "cumulative influence." A coating mixture of definite composition, which experience has proved to be suitable for a given paper, may be applied to a soft-sized body paper. The paper, after coating, may be insufficiently calendered. The ink for printing may be a trifle more tacky or tenacious than usual. All these conditions tend to lower the resistance power of the coating, and the printing results will be poor owing to what we term for want of a better name "cumulative influences."

DEFECTS IN "ART" PAPER.

The chief quality in a coated paper is a good surface, which must be hard enough to resist any tender "lift" and yet soft enough to allow the ink to be absorbed sufficiently without spreading in order that the effect of "setting off" may be avoided.

The hardness of surface depends on the proportion of glue in the mineral coating. If the amount is too small then the enamel comes away from the paper and adheres to the process block so that the picture is spoiled. This is technically known as "lifting." If however the amount of glue is too great, the ink is not absorbed quickly and it comes off on to the back of the next sheet of paper leaving the printing machine. This "setting off" is a serious drawback to rapid printing, in which the production of 1500 copies per hour is by no means an uncommon occurrence.

In colour work the presence of too much glue is also a defect since the colour will not lie flat and the result produced is very poor. A good surface gives a deep flat colour, but a surface which is too hard gives a mottled, washy and unsatisfactory result.

It may be noted that the super-calendering of a paper is something to do with the hardness of the surface. The main object of the polishing is to finally smooth down any slight irregularities on the paper, and to give a surface that will reproduce every detail in the block with accuracy. A little extra rolling to sheets which show a tendency to "lift" will sometimes improve the surface sufficiently for the work because the glazing slightly increases the power of the coating to resist the ink. The resistance obtained is only momentary, but before the coating time to become detached, the pressure of the rollers against the paper is removed, and the desired result is obtained.

The importance of these two factors, one of which is chemical, represented by the glue, and the other purely mechanical one, namely, the glazing or super-calendering, may be judged by a careful comparison of pictures printed on "art" papers containing varying proportions of glue and varying degrees of surface.

The conditions shown in Fig. III. are those of extreme cases, created in order to bring out clearly the influence

adhesive matter. Naturally the papermaker aims to obtain a good coating with a minimum of glue, but slight variations in the direction of glue from a standard which experience has proved for a certain class of work are found to be risky. In consequence of this, a paper coated for use with light ink blocks may pick off when employed with block-printing heavy dark shades. The production of a dense tint is always a severe test on an art paper.

INFLUENCE OF MINERAL MATTER ON PRINTING RESULTS.

Hand-made paper containing little or no mineral matter gives a picture that is blurred and indistinct, the depression of ink along the lines of the mark itself. Cheap printing paper with a small proportion of mineral matter, of loading, there is a slight improvement in result.

A machine finished paper containing about 16 to 18 per cent. of loading or mineral matter a marked improvement is obtained.

An imitation art paper containing about 30 per cent. of mineral matter, much of which lies on the surface of the sheet, the picture shows more detail.

Only in the art paper giving a smooth surface completely free of mineral matter, the clearness of the print leaves nothing to be desired. But it must not be looked that the surface is artificial and the paper is quite a secondary part, being sandwiched in, between two layers of mineral coating. In consequence of this the quality of the "body" paper is considered a matter of no importance, and many papers are merely composed of ingredients in which conditions essential for durability are chiefly remarkable by their absence.

The rationale of the process is therefore perfectly clear. In normal high-class writing paper, the absence of any mineral matter absolutely precludes an even surface, the glazing or polishing of these surfaces as produced by processes perfectly familiar to the papermaker, viz., the use of the super-calender, the plate-glazing rolls, etc., is not sufficient to give the desired effect. Usually, the print is blurred, indistinct, and lacking in detail and the curious outlining of the watermark is an indication of unevenness of surface. The examination of the surface of a high class linen paper reveals the existence of numerous fibres crossing and recrossing in every conceivable direction. It is obvious that even minute fibres occupy a certain volume, and the face of the paper at all such points of intersection is slightly above the spaces between them, and so an amount of pressure will bring them into one plane.

The addition of a small amount of mineral matter to fill up the interstices of the paper. The particles of mineral matter such as china clay, which is the usual material for cheap papers, distribute themselves around the fibres and fill up, more or less, the air spaces, and so reduce the irregularity of surface. The pressure of the action of the rolls in the super-calender reduces the minute undulations on the surface of the sheet in the case of a high-class rag paper, but the effect is not so pronounced. As the percentage of mineral matter is increased the improvement in the paper from the printing standpoint is noticeable, and is forced to the conclusion that the particular characteristic necessary in an "art" paper is only to be achieved by a complete degradation of the actual paper mineral substance which has nothing in common with the fibrous constituents.

The "imitation art" paper, which is a compromise between an ordinary cheap printing paper and the so-called high-class "art paper," contains a very high percentage of mineral matter which is brought up to the surface by a peculiar process of treatment, so that the surface of paper is rendered more suitable for half-tone printing. To use the word "paper" in connection with a material which consists of 35 per cent. china clay held together by a few low class vegetable fibres is an abuse of terms, but it is one which has some commercial value.

SUGGESTIONS AS TO SURFACE.

With such a purely artificial surface upon a cheap paper, which can easily be removed by friction with a moistened finger, it is evident that durability of pictures is scarcely to be expected.

The resistance of the art paper to the ravages of time is a matter which should not be difficult to determine, since all the elements for rapid depreciation are present in the shape of a large percentage of a cheap glue mixed with a common clay lying on the surface of a more or less inferior body paper, so that the moisture and damp of an ordinary atmosphere find books of this class an easy prey in course of time. The preservation of books containing the fine art illustrations obtained by the process of printing can be prolonged by careful storage in a properly dried room, but having regard to the large number of expensive got up books being continually published, this question is of the utmost importance.

In this case, as in many similar instances, the rule that "prevention is better than cure" holds good, but so far, the introduction of a fine art paper in which the smoothness of surface shall be an inherent quality of the actual paper, and not a mere artificial characteristic, has not been successfully accomplished.

There is a big field open for a systematic research into this question, which would afford considerable scope for chemical and mechanical ingenuity. No doubt the discovery of some method for obtaining a smooth surface without the employment of such adulterious substances as those which obtain at present would be extremely profitable to the inventor. Attempts have been made by the writer to obtain a coating by means of some form of dissolved cellulose, but without success. Investigation should probably proceed along the lines of the "Willesden process." In the manufacture of water-proof Willesden paper and similar goods, the body paper is passed through a bath containing cellulose dissolved in Schweitzer's reagent, an ammoniacal solution of cupric oxide. When this solution evaporates, a greenish mass of cellulose and copper oxide coats the whole surface, and the coating becomes intimately associated with the body paper by reason of the partial dissolution of the surface cellulose which takes place as the ammonia evaporates.

The colour of the final product is greenish, but the substitution of the copper by zinc brought about by treating the Schweitzer's reagent with metallic zinc, produces a colourless solution of the corresponding zinc salt, which has somewhat similar properties.

Other soluble forms of cellulose offer considerable attractions for research in this new field. The work of Messrs. Cross and Bevan, with the thiocarbonates and acetates of cellulose, are well-known in this connection, but the application of these soluble derivatives as a coating pure and simple has not yet met with any wide measure of success.

The attempt to produce a glossy surface on paper by the reprecipitation of a soluble cellulose seems to be a correct and scientific procedure, eliminating to a large extent the conditions which favour disintegration and the dissolution of three irreconcilable elements, the body paper, the mineral coating and the printers' ink.

Many of the difficulties experienced by printers using art papers may be overcome by careful attention to the conditions of working. The most important condition for successful work is that of an equable temperature. It is a matter of common experience that printing with art papers on Monday gives far more trouble than the work later on in the week, and that in the winter this difficulty is more pronounced. The general principle to be observed is the desirability of having the art paper, the ink and printing presses all at the same temperature and not only during the process of printing, but for some time before use. The regulation of the heat of the room to some fixed standard would do away with many troubles which are at present ascribed to the "paper" in some vague manner. Thus, for example, a given sample of ink may give satisfactory results one week because the supply has been kept in the printing room, while the next

week, being brought direct from a cold store room, it may give rise to endless trouble.

With regard to the ink which is used for printing on art paper, no systematic work has been done, and it is evident that a proper investigation into this question would result in some definite information. As the enamel on the art paper in its natural condition has a dull surface the ink must be of good quality. In general terms, the ink should have sufficient consistency to be tacky, the rollers should be hard and well seasoned, with a proper distribution of the ink by the inkers. In addition to the property of consistency, the ink should be manufactured in such a way as to dry quickly when placed on the surface of the paper. The consistency is determined by grinding down the colouring matter with as much strong varnishing as possible, the ink being thinned down if necessary afterwards, though the addition of too much medium varnish for this purpose tends to make the ink when dry flake away from the surface of the paper. The addition of driers is not always essential as the constituents of the ink pigment possess in themselves the necessary qualities for this purpose. It is hard to say whether the chemist can undertake the task of making up the ink, varnish to the required consistency and with the required tackiness and drying properties, because so many factors enter into consideration, many of which are of a mechanical nature, as already intimated.

Probably, just as important a factor is the nature of the paper itself. Successful printing can only be accomplished by practical experiment, and this seems to lie in the hands of the printers as much as in that of the ink manufacturer or paper maker.

Imitation Art Paper is largely used for catalogues and cheaper printings where clearness of detail is not so essential as in the best art papers. It is a very efficient substitute in many respects, but it lacks strength and durability. It is usually made by adding large quantities of china clay to a mixture of wood pulp and esparto, and producing a heavy loaded paper in which only a small proportion of rosin size is used. The paper is made on the machine in the ordinary way, and treated as it passes on to the calendars of the machine by means of the water doctor. This is a device which causes the surface of the paper to come into contact with water just before it is drawn through the rolls of the calendar. The somewhat bulky sheet wetted superficially in this manner is suddenly compressed by the pressure of the rolls and flattened down so that the surface has the appearance of a coating. The proportion of clay in an imitation art paper is often as great as 35 per cent., and this, coupled with the "soft sizing," is the cause of the somewhat limp feel and handle of this class of paper. It is, however, produced cheaply and answers its purpose.

Duplex coated papers may be produced by colouring a suitable coating mixture with one aniline dye for one side, and adding another to a coating mixture for the other side of the paper.

THE PRINTING PROCESS.

The production of a half-tone block from any photograph or picture is an interesting process, which may be described very briefly here. The picture is mounted on a board in front of a camera and brilliantly illuminated by means of two powerful arc lights placed on either side, and a photograph of the picture taken in the ordinary way except that a screen grating is put in front of the sensitive plate.

The screen grating is an important feature of the process, and is prepared in the following manner:—A sheet of plate glass of good quality is coated with an asphalt varnish. Lines are ruled diagonally at 45° across the varnished surface by an automatic ruling machine, which is capable of ruling parallel lines up to any degree of fineness. The number of lines per inch depends on the work for which the screen is to be used. For coarse, rapid work such as newspaper printing the lines are 50 to an inch; for book illustrations, the lines are 170–200 to an inch. The lines are etched on the glass by means of hydrofluoric acid, which eats away the glass along the lines ruled by the machine. A white enamel is rubbed into the etched lines, baked in by heat, and the glass

carefully polished. Two such glasses placed together with the lines crossing at right angles are cemented with Canada Balsam to form a screen grating.

The effect produced by the interposition of such a grating is to give a picture formed entirely of a very number of small dots, shadows being represented by closeness of the dots, and the lighter tones by various sizes. The gradation of the light and shade depends greatly on the experience and skill of the operator in adjusting the screen at a correct distance.

The *screen negative* is developed in the usual way used for the production of a print on a copper plate. The plate is carefully washed and coated with a sensitive solution, made by mixing fish glue, albumen, bicarbonate of ammonia, and dilute chromic acid in certain proportions. The plate, brought into contact with the screen negative, is exposed to an arc light, for a period of 6–8 minutes and then thoroughly washed in order to remove the portions of the coating not rendered insoluble by the light.

The washed plate is then immersed in a bath of aniline dye, usually methyl violet, which stains the plate and renders all the detail clear and distinct. When the plate is enameled by the heat of a Bunsen flame the colour of the picture changing from blue to grey, and finally to a deep brown tone. When this point is reached the plate is cooled down, and the coating resembles a hard enamel.

The "etching" process requires a good deal of skill and technical experience, as well as a knowledge of the effect. The process is a simple one, involving the immersion of the plate, the back of which has been previously coated with black varnish, in a bath of weak nitric acid, the dots being protected by the enamel remaining intact, and the spaces between are eaten out by the acid.

From this plate a rough proof is taken, which the operator the opportunity of determining how far further the etching process must be taken, and then to which it may be necessary to etch some portions of the plate deeper than others in order to give good effect in the final picture. The finished block is mounted on a slip of wood, and in that condition is ready for the printer.

DISCUSSION.

MR. CLAYTON BEADLE said there was no doubt that the introduction of the so-called "art papers" had given a further stimulus to the use of china clay. There was one class of paper which he did not think the speaker had referred to, that was the paper made by what he called the "water finish." It was not a coated paper, but was treated in a peculiar way. The paper was sized with a thin film of water before it passed over the calendars, and this treatment imparted to the surface a characteristic finish which rendered it capable of receiving impressions from process blocks. So far, this paper had not been so successful as the coated paper. Undoubtedly, the effect of the art paper was a very unfortunate one. The cellulose was absolutely transparent. It was due to the peculiar structure of the fibres which caused the light which falls upon their surface to be reflected and reflected in every conceivable direction that the pure white effect was produced. When such a substance as china clay was introduced, either on the surface or into the body of the paper, a truly opaque surface was produced, and no amount of crushing would render the paper transparent. He thought that the proportions given by Mr. Simonds of the amount of casein and glue were greater than frequently employed in practice, either in this country or on the Continent. On the Continent they were ahead of the British with regard to coating paper. They were able to use a body paper containing the very cheapest material, sometimes 50 or 60 per cent. of mechanical wood, whereas in this country 50 per cent. of esparto grass was used with 50 per cent. of chemical wood to produce the same effect. They were more skilled in the actual coating of the paper, and a cheaper and commoner body paper could be employed to get a similar result as to the external appearance went.

MR. WALTER F. REID said the two materials mentioned were apparently generally used for enamelling paper.

nd casein, and it would be difficult to choose two als which were more readily decomposed in the of time, especially if they got damp. As Mr. had said in the closing remarks of his paper, there great opening for other materials, but there was considerable difficulty in using materials allied to se or which contained a solvent of cellulose. He ed experiments with nitro-cellulose solutions, and und that when the fibres were cemented too closely er the paper invariably became brittle. If the g were only on the surface of the fibres it was apt arate with frequent bending of the paper. He had ted thick cardboard of a spongy nature until it ed like wood; and he had extracted the coating al, and the cardboard became as supple as it was . That was one of the great difficulties that were ith, but he thought that up to a certain percentage ing was a necessary adjunct, the paper itself being too . By coating with a mixture of mineral matter and paper was produced which could not stand the ay wear and tear. A great deal of the literature of esent day was read and thrown away at once, and was great danger in printing works of scientific and al importance on paper which, as Mr. Sindall had y pointed out, was not durable. He thought those ers of the Society who had the opportunity could o better than devote themselves to this question, was one that contained great industrial possi-

H. P. STEVENS said that the diagrams which showed lect of printing on paper containing various pro- ns of mineral matter and glue or gelatin was very sting. Mr. Sindall also referred to the calendering a paper as also producing that effect, but surely ight be other factors which affected the way ich the paper took the print; for instance one e the variety of glue employed, and he should o have heard Mr. Sindall's opinion as to some e more important qualities which he would or in a suitable glue. (Glue was used for a number oposes, not only for coating paper, but for sizing, o on, and naturally the quality of glue which would per for sizing purposes would be different from or coating. Mr. Sindall had spoken of satin white sisting of barium sulphate and alumina; the common white was, however, prepared from slaked lime and r aluminium sulphate. He believed that the whites frequently consisted of nothing more than itated calcium sulphate, and they did not usually in barium, or, at any rate, very little.

R. W. SINDALL said that imitation art paper was eed by what was termed "water finish." In the ss a very large percentage, perhaps 30 per cent., of clay was mixed with the pulp in the beaters, the paper passed through the calenders, and the water was ght into contact with it by means of a roller which kept wet, the result being that as the paper came igh the rollers the clay was brought up to the surface. regard to the proportions of the glue and casein, h he had quoted, many of the figures were derived his own practical knowledge and experience, and of them had been given to him. He had no doubt uch of the ordinary art work they could do with as as 15 per cent., but with normal everyday printing, had to produce a paper which would stand the rest conditions. With regard to the use of ived cellulose as a coating material, the unfortunate g was they could not easily get rid of the by- ducts of the chemicals used as the solvents. That one of the drawbacks of attempting to produce an paper from dissolved cellulose. e had not gone into the question of the influence of quality and varieties of glue, but the subject was one ch needed investigation. It was necessary as far as ble to connect the analytical results obtained in the oratory with the practical results obtained in the ing offices or in the mill. That was an investi- on which the paper makers did not carry out them- es; they expected it to be done in the laboratory, re it was not always possible.

Meeting held at Burlington House, on Monday, July 10, 1905.

MR. A. GORDON SALMON IN THE CHAIR.

THE INFLUENCE OF GELATIN SIZING ON THE STRENGTH OF PAPER.

BY CLAYTON BEADLE AND H. P. STEVENS.

As far as we are aware no systematic attempt has been made to determine the influence of different percentages of gelatin on the physical constants of a waterleaf paper. It is generally known, of course, that gelatin increases the strength of a paper, and that the increase is in some way connected with the percentage of gelatin added, but, so far, no tables or diagrams have been published showing the effect of different proportions of gelatin on the strength and stretch of paper.

Before describing our work we will briefly refer to two communications bearing on the subject which have appeared in German trade journals since the completion of our work. Both these papers, however, cover a different ground to our own as in neither of them is any attempt made to trace the effects of different proportions of gelatin.

The first of these papers is by E. L. Selleger, and appeared in the "Papier Fabrikant." For these experiments the strength and stretch of the papers were measured before and after treatment with animal size. As most of the experiments were performed on previously, rosin-sized papers they are hardly comparable with our own. The only experiment on a waterleaf paper containing no rosin gave to following results:—

A. *Unsize Paper* (weight per sq. m., 55 grms.): mean breaking length, 6,300 m.; mean elongation, 5.4 per cent.

B. *Paper Sized with Animal Size* (weight per sq. m., 60 grms.):—Mean breaking length, 7,260 m.; mean elongation, 7.4 per cent.; increase on breaking length, 960 m. = 15 per cent.; increase in elongation, 2 m. = 37 per cent.; increase in weight per sq. m., 5 grms. = 9.04 per cent.

Unfortunately the author gives no information as to the quantity of the gelatin used.

The second paper appeared in the "Wochenblatt fur Papier-Fabrication" in connection with the choice of suitable materials for bank note papers. As no information is given either in respect to the strength of the sizing bath or the amount of gelatin taken up by the paper, it is not possible to compare these results with our own.

The effects of rosin size upon strength of waterleaf papers have in a small measure been investigated. For many years it was supposed that the addition of rosin size in all cases diminished the strength of the paper. By conducting a number of sizing trials with known quantities of rosin size in papers of known composition one of us was able to show that in many instances the reverse is the case, namely, the rosin size increasing the strength of the paper. Within certain limits this increase was found to be in proportion to the amount of rosin fixed by the fibres.⁽¹⁾ Thus, when papers contain a very large proportion of mechanical wood, and in their waterleaf state show very low tensile strength, this strength is increased by the addition of rosin, whereas, if the waterleaf strength is high, the addition of rosin tends to diminish the same. It appears, therefore, that the addition of rosin is such that under normal conditions it increases the strength of very weak papers and decreases the strength of very strong ones, whilst papers of intermediate strength are little affected. In the original communication an attempt was made to represent this numerically, and it would appear possible to calculate the strength of a rosin-sized paper if the waterleaf strength, percentage of rosin, and rosin strength factors were known. Under abnormal conditions, however, but under conditions that not infrequently occur in ordinary practice, such as in a very damp atmosphere, or when the paper is artificially damped, the rosin affords some protection to the fibres. In such

uses it appears that under all circumstances of comparison the resin-sized paper is stronger than its water-leaft, provided the amount of resin present be not too small. At any rate this has been our experience so far. It will be readily seen, therefore, that the influence of resin upon the strength of paper is one of extreme complexity and dependent upon many factors. It is therefore a difficult subject to investigate, and it is hardly surprising that the work of different observers has led to conflicting conclusions.

In many commercial papers the subject is still further complicated, from the fact that the paper is first resin sized and then tub-sized with gelatin. We mention these facts because they may assist in some measure in a better grasp of the subject with which we are about to deal.

Many papers of the highest class, such as drawings, jeans, banks, high-class writings, &c., are still sized with gelatin alone. We propose to simplify matters by dealing only with these.

We will now briefly review the earlier work which has led up to the researches undertaken on behalf of this communication. One of us undertook, at the request of Messrs. George Newnes, Ltd., a series of researches, among the chief objects of which was to investigate the influence of sizing paper with gelatin.⁽²⁾ Samples of paper of different fibrous composition were cut in transverse section, both in the machine and cross direction, from which photomicrographs were produced. These sections if focussed critically can be made to show the section of the individual fibres, transverse and longitudinal, which assist in determining the direction in which these fibres are placed, but what perhaps is more interesting is that they can be made to reveal the nature of the interstices of the paper, from which we can form some conception of the manner in which gelatin should be distributed. It must be remembered that these interstices as revealed by magnification of the sections have to be bridged over by microscopic films of gelatin to give the paper the necessary ink-proof qualities.⁽³⁾ The general distribution of the fibres has furthermore been investigated by splitting paper into laminae sufficiently thin to permit the light to penetrate freely; such laminae should not for such purposes consist of more than one layer of fibres.⁽⁴⁾ Such laminae made it evident that on the top surface of the paper the distribution and direction of the fibres is different from that of the middle or of the underneath layers, and it affords further proof of the statement of Schubert that papers are disposed in natural laminae.⁽⁵⁾ The reason for this has been traced to the peculiar action of the wet end of the paper machine whilst the wet web is in process of formation. These researches led to the determination of what we call the direction of "least expansion when wetted," which was proved ultimately to coincide with the mean direction of the fibres.⁽⁶⁾ By aid of the above-mentioned laminae note was taken of the direction of different fibres. Tables were constructed showing the direction of each individual fibre, from which the mean direction in each case was calculated.⁽⁷⁾ With machine-made papers the mean direction of the fibres corresponds within a degree with the "machine" direction, i.e., the direction in which the paper travels on the machine. As the greatest strength would naturally be in the predominating direction of the fibres, it had for years been argued that the fibres pointed in the machine direction. The above measurements proved this supposition. These laminae have furthermore shown that the watermarking of paper is rendered visible to the naked eye, not so much from the difference in the thickness of the design as compared with that of the background, but from the fact that the fibres are disposed in opposite directions, running (in ordinary laid papers) at right angles to the line of the wire marks in the thinner places; and parallel to them in the thicker places.⁽⁸⁾ The reason for this appears to be that the fine wires of the "dandy" at the moment of contact with the soft stuff on the machine wire push aside all those fibres parallel with themselves, whereas these wires are unable to influence those fibres at right angles.

For the purpose of investigating the strength of papers in different directions, papers were tested by the "fan method."⁽⁹⁾ In machine-made papers the cross direction of the web, i.e., that at right angles to the direction in

which the paper travels on the machine is described as 0° or 180°, thus forming a base line for measurement machine direction being 90°. Strips of paper 3 in. by 1 in. wide were cut at every 10° from 0° to 90° at some cases at every 5°. These were tested for tensile strength, which is expressed in pounds, and for elongation, the time of fracture, which is expressed in percentage, the distance between the clips which hold the paper in the testing machine. Diagrams plotted, showing the fluctuation of strength at these different angles, were found instructive. The strength is always greatest when the paper is pulled in the machine direction, and least when pulled in the cross direction or near to it. When tested every 5° it is generally found that the strength is at a minimum a few degrees from the cross direction, although always at its maximum in the machine direction. I tested every 10° the divergence of minimum strength from the "cross" direction is naturally lost sight of. The reason for this slight divergence can be traced to the action of the paper machine.⁽¹⁰⁾

As a general rule with machine-made papers the elongation (or "stretch," as it is usually called) is in the order to the strength; thus the "stretch" is greatest when pulled in the "cross" direction and least when pulled in the "machine" direction.

Hand-made papers are generally supposed to have uniform strength, or nearly so, but unfortunately far from being the case with a great deal of the hand-made paper. With a view of investigating this point a number of well-known hand-made papers were tested by the "fan" method for strength and for stretch. For particular make of hand-made papers it will be found that there is one spot or position on the sheet which gives the greatest strength when pulled at a particular angle and another in another position of the sheet and at a different angle which gives the least strength. That which gives the greatest strength gives the least stretch and *vice versa*.⁽¹¹⁾ There are far greater complexities in the physical qualities of hand-made than with machine-made, complexities partially arise from the "personal equation" of the vatman who makes the sheet, but also very largely from the manner in which the mould is dipped into the vat, which is common to all hand-made papers.

With machine-made paper, if prepared with care and uniformity, all strips cut parallel to one another, no matter at what particular angle or part of web, have approximately the same tensile strength.⁽¹²⁾ With hand-made papers this is not the case. Thus, if a sheet of hand-made be divided up into numerous parallel strips, the strength will be found to depend upon their position in the sheet.

The fact that the near deckle edge (i.e., that edge directly underneath the letters on the watermark and running parallel to same) is dipped first into the vat, and the edge parallel to it is the last to receive the vat, results in the production of paper, which has quite a different "tear" on the near deckle edge to that on the far deckle edge. This difference is noticed whether the paper be made parallel to or at right angles to the respective deckle edges. An experienced paper-maker can tell by his eyes shut by tearing the paper which of these two deckle edges the tear is close to, and with the naked eye the difference of tear is apparent even to the casual observer. By a series of tests on strips cut in different directions near these two deckle edges, the probable cause of this difference has been revealed, and on closely following the motions of the mould, the reasons for these differences can be grasped. These physical tests show a difference of strength and stretch at different angles, which difference is not popularly supposed to exist.

As to the strength of hand-made paper when pulled at right angles to these "near" and "far" deckle edges the matter is different, that on the right of the vatman running to and from him is in every way similar to on his left running parallel to same, but it differs entirely both in tear, strength, elasticity, and other qualities from the condition of the paper along the near and far deckle edges. The middle of the sheet is affected by four deckle edges, and in a square sheet where the edges are equi-distant, the effects of these respective influ-

might almost be calculated for any angle. The material contained in the corner, is, of course, brought under the influence of the two edges enclosing the angle. The forces which these two edges exert are at right angles to one another, but one edge very much preponderates in its influence over the other.

Speaking generally, hand-made paper is strongest at or near the direction in which the vatman looks when making the sheet, and is weakest at right angles to this direction. The reason of this is, that in process of lifting the mould out of the vat a wave is produced, which traverses from the vatman to the opposite side of the deckle. This wave tends to set the fibres in the direction in which the wave traverses, and so gives the greatest strength to the paper in this direction. Although the vatman shakes the mould in the opposite direction to overcome this influence, the first wave is so great in its effect as to preponderate over all subsequent influences.⁽¹³⁾ Hence, the difficulty in making hand-made papers absolutely uniform in strength. We do not wish it to be supposed that hand-made papers are inferior to machine-made. The reverse is undoubtedly the case. We are dealing here with small differences. Hand-made and machine-made papers may be compared to ivory and ivory substitutes respectively. The former is much superior apart from its sentimental value in spite of the fact that its physical qualities are somewhat unequal or irregular. We have given numerous foot-note references in order that those desirous of sifting the evidence on which these conclusions are based can refer to the original publications.

This concluding references to the researches undertaken on behalf of Messrs. Newnes, we will now proceed with our joint work.

In passing, we must briefly refer to a series of comparative trials on the strength-giving qualities of different gelatins abstracted in this Journal.⁽¹⁴⁾ That gelatin, marked P in the list, was the one chosen for trials, about to be described. By studying the original communication it can easily be seen how this sample compared in its various qualities with the other samples which it was matched against. The waterleaf paper was also of the same make as that used in the following investigation.

It is obvious from what is said above that, it would be an extremely difficult thing to investigate the exact influences of different proportions of gelatin upon a hand-made paper. We made numerous tests with this object, but without success. Although much useful information was obtained, it was not of such an order as to admit of representation in a diagrammatic form. We found it necessary therefore to select a machine-made paper for the purpose.

The paper selected for our experiments was a typical machine-made cream laid waterleaf; containing about two-thirds cotton and one-third linen; substance about 27 lb. large post. It was cut into convenient strips, each sheet being carefully weighed. Some of these strips were tested for strength and elongation in both machine and cross directions, the results of which are given in Table I. The first three horizontal columns of the table give the average of eight tests and the fourth gives the average of the first three. It will be noticed that the paper selected was wonderfully constant and uniform in its physical qualities, this being essential in trials where slight differences have to be observed as the result of small additions of gelatin. To obtain this uniformity as above explained, a machine-made paper had to be selected. The strips of waterleaf were treated with gelatin solution at 130° F., containing no alum or soap. The strips were first laid on the surface, and when the gelatin had soaked through on to the top surface they were immersed and immediately afterwards passed through rubber squeezing rolls, again weighed, and hung up to loft dry in air at 60–65° F. After drying, they were again weighed. They were then put together and kept about a week in air at the same temperature and tested for tensile strength and elongation, in the same manner as the waterleaf (Table I.)

Table 2 shows how the percentage of gelatin taken up by the waterleaf in each case was arrived at. The quantity of gelatin is proportional to the strength of the bath.

The description at the head of each column is sufficiently explanatory.

Table 3 gives an individual test in detail of a leaf sheet.

Table 4 gives full details in regard to the whole of the tests.

The curves as shown on Figs. 9 and 10 when taken in conjunction with table 4, speak for themselves.

A curve can be drawn, as shown in Fig. 9 through various mean figures of machine and cross directions. A quite unexpected result was produced by the addition of 0.43 per cent. of gelatin. Instead of a slight increase in strength a decrease took place. On repeating the experiment, with a solution of gelatin of the same strength as before, a similar result was obtained. The effect of the addition of a very small percentage of gelatin is therefore to decrease the strength, particularly in the machine direction. On increasing the proportion of gelatin strength again rises so that with the addition of 0.7 per cent., the sized paper has the same mean strength as the waterleaf, after which there is a rapid increase. The approximate increase at different stages are summarised in Table 5. The ratio of machine to cross direction in respect to strength, shows a greater difference with the waterleaf than with the sized papers, the ratio remains fairly constant with proportions of 1 per cent. to 5 per cent. of gelatin. With larger quantities of gelatin, the difference is less marked.

By reference to Figs. 9 and 10, a papermaker can get some idea of what increase in strength will be produced by the addition of different percentages of gelatin in sizing. As the quality of the gelatin may influence the results somewhat, it is well to note that the gelatin was of good quality, such as might have been chosen by papermakers for the sizing of rag papers. We do not, however, anticipate that the general character of the gelatin would be affected by the quality or properties of the gelatin, although we have good reason to believe that the extent of the increase in strength would be largely influenced by the character both of the gelatin and the leaf used.

Fig. 11 shows the character of the curves of elongation at time of fracture, which should also prove of use to papermakers for the purposes of reference, particularly in cases where it is desired to produce a paper of definite elongation, or where the latter must lie within certain limits as is often the case for H.M.'s Stationery Co.

We attach considerable commercial importance to the description of work which we have endeavoured to bring before your notice in this paper.

For the great majority of purposes, unsized waterleaf is of no service. For the purpose of printing and writing upon, to impart to the sheet its necessary hardness to enable it to be used for multifarious purposes, the paper must either be rosin-sized or tub-sized.

The addition of sizing materials profoundly influences the physical qualities of the paper. A waterleaf of strong materials frequently has little strength until it has been sized with gelatin, but the influence that the gelatin will have upon the paper is entirely dependent upon the character of the fibres of which it is composed. Waterleaf has latent properties, which, in a large measure, only make themselves manifest after the addition of gelatin. A more exact knowledge of these changes is much to be desired. Although we have extended our tests over a large range of papers and made them as exhaustive as possible, we do not feel justified as yet in dogmatism too much, but our results, such as they are, may, we think, be of service to papermakers and users of papers, and a knowledge of the methods we have employed will, we hope, stimulate others to give the subject closer investigation.

In conclusion, we beg to thank Mr. John Christie for his kindness in permitting us to use lantern slides from his photomicrographs, many of which were prepared for us to assist our researches, and to Messrs. George N. P. Ltd., for permission to reproduce lantern slides from their diagrams, both of which have been of material service in illustration of this paper.

DISCUSSION.

STEVENS wished to point out that the experiments of strength of tub-sized papers prepared in this way be followed more closely by laboratory experiments than others. It was possible to closely imitate the effects of treatment with gelatin that was actually lost in the mill, and consequently the results obtained were of practical value.

Meeting held at Chemists' Club, on Friday, May 19th, 1905.

DR. RUSSELL W. MOORE IN THE CHAIR.

DESCRIPTION OF METHODS EMPLOYED IN PREPARING THE TABLES OF SPECIFIC GRAVITY OF SULPHURIC ACID, NITRIC ACID, HYDROCHLORIC ACID AND AMMONIA, ADOPTED BY THE MANUFACTURING CHEMISTS' ASSOCIATION OF THE UNITED STATES.

BY W. C. FERGUSON.

INTRODUCTORY.

The General Chemical Company, finding that many different methods of analysis were being used in their various works, and realizing the advantages of uniform methods, submitted the task of unification to the writer. After careful investigation, the methods best adapted were selected, and by the constant examination of new methods described in the literature as well as by original research, these methods are from time to time substituted or modified. The need soon became apparent for uniform specific gravity tables, no two authorities agreeing; not only was there disagreement between specific gravities and corresponding percentage composition when reduced to the same standard, but different moduli, temperatures, &c., were used as standards.

The preparation of standard tables of the specific gravity

and corresponding composition, with other useful data, was undertaken for nitric acid, hydrochloric acid, ammonia and sulphuric acid. "The Manufacturing Chemists' Association of the United States," hearing of our efforts while the work was in progress, after investigation, accepted the tables as they were completed as standard tables of the association. In the case of the sulphuric acid table, they employed Prof. H. P. Talbot of the Massachusetts Institute of Technology of Boston, as expert, whose name appears with that of the writer as authority.

These tables are designed primarily as a basis for sales which are largely governed by the degree Baume; they are also useful for controlling processes, taking account of stock, &c.

The acids and ammonia used were the purest obtainable C.P., and were carefully examined for impurities and purified when necessary. The impurities in commercial products are such a variable quantity and, as their purity is becoming more pronounced as manufacturing processes improve, many substances made on a large scale being nearly C.P., it was deemed that the tables would have more practical value if they were based upon C.P. compounds. As to any scientific merit they may possess, it is needless to say that such a positive basis to which they can always be referred is an essential.

All of the analytical and sp. gr. determinations, determinations of the co-efficient of expansion (or allowance for temperature), determination of boiling points, as well as all calculations and clerical work, were performed by two experienced men working independently.

SPECIFIC GRAVITY DETERMINATIONS.

All specific gravity determinations were taken at 60° F., compared with water at 60° F. The work was done in winter and no account was taken of differences of atmospheric pressure or temperature, which averaged about 760 mm. and 65° F.

The apparatus used in this work was a 50 c.c. Geissler pycnometer having a capillary side arm tube fitted with a glass cap, in the top of which was a small hole which allowed the liquid to expand without loosening the thermometer or cap, at the same time preventing loss while weighing. The thermometer, which was ground to fit the neck of the bottle, was graduated to 1/9° F. and readable to 1/18° F., and was frequently checked against a standard thermometer.

Before making a determination the water content of the bottle was first accurately determined and checked from time to time during a series of determinations. To obtain the water content, the bottle together with the thermometer and glass cap were carefully cleaned, dried and weighed. (The accuracy of the balance and weights were systematically checked against a standard set of weights.) The bottle was then filled with freshly distilled water at 55°–57° F., and the thermometer tightly inserted. As the temperature slowly rose, the water expanded through the capillary side-arm. When the thermometer registered 60° F., the last drop was removed from the top of the capillary, the tube capped and the whole weighed. This weight, less the tare obtained above, was taken as the water content of the bottle at 60° F. (Check determinations agreed within 0.002 grms., or less than 0.00005 sp. gr. Distilled water freed from carbon dioxide by boiling, and cooling in a closed vessel, gave the same water content as the ordinary distilled water which was used throughout the work. This water was free from chloride and residue upon evaporation.)

In determining the sp. gr. of liquids, the weight of the liquid contained by the bottle at 60° F. was obtained as above. This weight, divided by the water content, equals the sp. gr.

It was thought that the temperature of the liquid in the bottle might vary in different parts and the whole not have the same temperature as registered by the thermometer in the centre of the bottle. To ascertain the facts in the case a beaker was filled with water below the temperature of the room, and a thermometer placed in the centre of the beaker showed the same temperature as those placed near the sides, the temperature rising uniformly throughout the liquid.

COEFFICIENT OF EXPANSION.

The correction for temperature was found by allowing the liquid to slowly expand, and when the temperature had risen 8°–10° F., the tube was wiped off and the apparatus again weighed. Another weight taken at a still higher temperature, and from these the difference in sp. gr. for 1° F. and the number of degrees corresponding to 1 B. were calculated. To determine how much the expansion of the pycnometer affects sp. gr. determinations at different temperatures, the bottle was filled with distilled water and weighed at 50°, 60° and 80° F. From Kopp's table of the volume of water at different temperatures, the increase in volume of 5 cc. for each 10° F. was calculated. If the bottle had expanded, the successive differences in weight should corresponded with the differences in volume, but in case the differences in weight were less than the calculated expansion of water, the amount less being due to expansion of the glass bottle. The results showed 1° F. = 0.00062 grms. = effect of expansion of 50 c.c. 100 c.c. = 0.0012 grms. which would make a difference of 0.00012 sp. gr., which is less than the accuracy of determinations, and no correction has been made for it.

Analytical Determinations.—All calculations are upon F. W. Clarke's Table of Atomic Weights, 1906, p. 16.

Preparation of Standards.—The following standards were prepared by the methods to be described:—Sodium carbonate (a) ignited at low red heat to constant weight; sodium bicarbonate (b) heated at 572° F. to constant weight; ammonium sulphate; 100 per cent. sulphuric acid; sulphuric anhydride; sulphuric acid.

Sodium Carbonate (a).—This standard was prepared from the purest obtainable sodium bicarbonate by the ammonia process and specially selected for use by a prominent manufacturer. Our analysis showed it to contain in addition to some sodium chloride—

	Per cent.	equivalent	Na ₂ CO ₃	Per cent.
SiO ₂	0.001			= 0.00
Fe ₂ O ₃ .Al ₂ O ₃	0.002	"	"	= 0.00
CaCO ₃	0.010	"	"	= 0.0106
MgCO ₃	0.009	"	"	= 0.0113
	0.022			0.0219

The impurities that are titratable by an acid, calcium and magnesium carbonates, are exactly equivalent to the sodium carbonate displaced.

About 200 grms. of sodium bicarbonate were washed in a funnel having a porcelain plate until entirely free from chloride. It was then dried at 100° C., protected from acid gases, finely ground, and kept in a sealed bottle until used. About 20 grms. of bicarbonate thus prepared was heated in a platinum dish at a moderate red heat until the weight was constant, and then 5 grms. was quickly and accurately weighed for analysis. Our attention was directed to the method of heating sodium carbonate for standardising, various results were obtained depending on the temperature of ignition, the highest temperature giving the greatest alkalinity, or about 0.09 per cent. greater than the lowest. It remained to be ascertained whether the high or low result was correct, and whether in heating to the higher temperature (red heat or a Bunsen flame) water was given off, or whether the weight was due to a decomposition of sodium carbonate into sodium oxide and carbon dioxide.

In referring to the literature several references were found upon the ignition of sodium carbonate. Menzies, Vol. I., p. 525, in quoting the work of Pickering, says: "When sodium carbonate is fused about 1 per cent. of carbon dioxide is disengaged." In Lunge's "Untersuchungen Methoden," Vol. I., p. 83, reference is made to an article in Zeitschr. f. Angew. Chem., 1897, p. 5, in which he says that soda intended for the standardisation of acids must not be heated higher than 300° C. (572° F.), and if the heating is carried on at this temperature for a sufficient length of time, one is not sure that neither bicarbonate nor water is left behind, yet no sodium oxide has been formed as may happen if the heating is carried to a low red heat.

Sodium Carbonate (b).—A portion of the washed

carbonate was carefully heated in a platinum dish with occasional stirring at 572° F. to constant weight and immediately analysed.

Ammonium Sulphate.—10 grms. of the standard acid hereinafter described) were quickly and accurately weighed in a small glass weighing tube, avoiding absorption of moisture from the atmosphere. After rinsing the sample in a large platinum dish, it was made slightly ammoniacal with ammonia that had been freshly distilled to free it from lime. During evaporation on the steam bath, the dish was kept covered by a large funnel and protected from acid fumes. Ammonia was added from time to time as it was found that the salt became acid on evaporation. After evaporation the dish was dried in an air bath to constant weight at 230° F.

Sulphuric Acid (100 per cent. H_2SO_4).—In reviewing the work of Pickering (J. Chem. Soc., 1890) it occurred to me that it would be possible to make some pure 100 per cent. sulphuric acid, and that the analysis of this would serve as a suitable check on our other methods. Pickering has shown that the curve of the melting point of sulphuric acid near 100 per cent. reaches a maximum at 99.8 per cent. Therefore, by starting with an acid slightly above 100 per cent., and another slightly more than 99.8 per cent., a point should be reached in recrystallising the successive crops of crystals obtained from both solutions should show the same per cent. sulphuric acid, as is actually the case.

Starting with two litres of chemically pure sulphuric acid, distilled sulphuric anhydride was added until, on analysis, the strength was 99.8 per cent. The bottle was then drained off through a porcelain plate fitted with the mouth of the bottle and having a glass tube passing through its centre to the bottom of the bottle in which air dried with strong sulphuric acid was used, when the bottle was inverted. By draining the crystals for several hours at a temperature slightly above the melting point, the mother liquor was entirely removed. These crystals were then melted and recrystallised and drained as described above. The crystals thus obtained were melted, recrystallised and drained, the final crystals being melted and kept in a sealed bottle until used. Two litres of acid were prepared, analysing 99.8 per cent. sulphuric acid. From this the standard acid was prepared in exactly the same manner as in the case of analysing 99.8 per cent. sulphuric acid.

Sulphuric Anhydride.—Another method used as a check standard was the titration of sulphuric acid formed by the addition of water to 100 per cent. sulphuric anhydride. To do this required especial care—first, to obtain a sample of sulphuric anhydride free from water, after obtaining it, to mix it with water without loss of anhydride. The plan adopted was as follows:—

Using sulphuric acid containing 40 per cent. free SO_3 distilled at a low temperature into a long-necked flask fitted tightly over the delivery tube of the retort. Crystals of potassium permanganate were added to the flask to destroy any sulphur dioxide present. The first 25 c.c. of the distillate were rejected. About 200 c.c. were then collected. Then this 200 c.c. was redistilled, rejecting the first few c.c. and collecting about 100 c.c. in an ordinary delivery flask, to the delivery tube of which was sealed the end of a test tube, which had been drawn out in the middle, and bent at the constricted part, almost to a right angle, thus forming a receiver. As soon as the distillation into the flask was completed the neck was sealed, thus making the whole apparatus air-tight. By heating the flask to 140° F. and cooling the receiver, about 20 grms. of sulphuric anhydride were distilled into the latter, which was then sealed at the constricted part, having a slight vacuum.

Phanilic Acid.—In looking through the list of organic acids for one that would be suitable, sulphanilic acid was selected upon account of its being a monobasic acid of a high molecular weight, crystallising without water and without decomposition. The so-called C.P. acid was recrystallised three times, finely ground, and dried in an air bath at 230° F. to constant weight.

ANALYSIS OF STANDARD

For the comparison of the above carefully prepared compounds as standards two litres of C.P. sulphuric acid were used. This acid was tested for impurities, found to be practically free, and was kept sealed when not in use, its percentage composition being determined as follows:—

Sodium Carbonate (a).—5 grms. of freshly ignited sodium carbonate, prepared as above, were quickly weighed out, and an amount of standard acid, slightly in excess of the amount required for neutralisation, was weighed in a small weighing tube and washed into a flask containing the sodium carbonate. After boiling for 15 minutes to expel carbon dioxide, the excess of sulphuric acid was titrated with N/2 sodium hydroxide, using phenolphthalein as indicator. A short stem funnel was placed in the neck of the flask to prevent loss while boiling. Duplicate analyses of the standard acid by this method gave 97.33—97.35 per cent. of sulphuric acid.

Sodium Carbonate (b).—5 grms. sodium carbonate, prepared as above by heating at 572° F. to constant weight, were used in determining the strength of our standard acid. Observing exactly the same conditions described above, we obtained 97.41—97.42 per cent. sulphuric acid.

Ammonium Sulphate.—The ammonium sulphate dried to constant weight at 230° F., as described above, was cooled in a desiccator and quickly weighed.

The salt was then dissolved in water and the small amount of free acid present, as indicated by Methyl Orange, was titrated with N/3 sodium hydroxide. Adding an equivalent weight of ammonia to the weight above, gave 97.41 per cent. as the strength of the sulphuric acid. The amount of acid titrated was less than 0.10 per cent. (with Methyl Orange a sharp end point is obtained). A duplicate analysis gave 97.41 per cent. of sulphuric acid.

Sulphuric Acid (100 per cent. H_2SO_4).—About six grms. of acid, crystallised from 99.8 per cent. sulphuric acid, as described above, were introduced into the bottom of a small weighed tube by means of a long-stemmed dropping tube manipulated with a rubber bulb. The glass stopper was then inserted in the tube, the whole weighed, after which the acid was carefully washed into a casserole containing cold water, and titrated with sodium hydroxide solution, using phenolphthalein as indicator, according to the method to be described.

Assuming this acid to be 100 per cent. sulphuric acid, and using the NaOH solution standardised on this basis to determine the composition of the standard acid, duplicate determinations gave 97.39—97.41 per cent. sulphuric acid. Acid crystallised from 100.1 per cent. sulphuric acid. Using this standard exactly as in the preceding our standard acid analysed 97.40 per cent. sulphuric acid.

Sulphuric Anhydride.—The tube containing the sulphuric anhydride was weighed and placed in a glass-stoppered bottle containing about 100 c.c. of water. The tip was broken off above the level of the water and the bottle sealed. After standing in a warm place for three days, the sulphuric anhydride had distilled out of the tube and was absorbed by the water, thus mixing without any loss of sulphuric anhydride. The glass tube was dried and weighed, and, deducting this weight from the weight above, we have the weight of sulphuric anhydride. The resulting acid was diluted to one litre and 300 c.c. measured with the dividing burette were titrated with sodium hydroxide solution, using phenolphthalein as indicator, boiling out carbon dioxide and observing the same conditions as in standardising.

Assuming the sulphuric anhydride to be absolute, and using the sodium hydroxide solution standardised on this basis, to determine the strength of the standard acid, it was found to be 97.40 and 97.43 per cent. of sulphuric acid.

Sulphanilic Acid.—20 grms. of this acid, prepared as described above, were titrated, using about 95 c.c. of sodium hydroxide solution, phenolphthalein as indicator, and observing all conditions as in standardising with sulphuric acid. Assuming the acid to be 100 per cent. pure, and using the sodium hydroxide solution standardised

on this basis to determine the strength of our standard acid, it was found to be 97.41 per cent. of sulphuric acid.

Recapitulation of composition of standard sulphuric acid referred to all the standards employed:—

	Per cent	Average
Sodium carbonate—		
(A) Ignited at low red heat to constant weight	97.33 97.35 97.41 97.42	97.34
(B) Heated at 572° F. to constant weight		97.415
Ammonium sulphate method	97.41 97.41	97.41
100 per cent. sulphuric acid prepared from acid slightly under 100 per cent.	97.39 97.41	97.40
100 per cent. sulphuric acid prepared from acid slightly over 100 per cent.		97.40
Sulphuric anhydride	97.40 97.43	97.415
Sulphanilic acid	97.41	97.41

The close agreement between the above standards, with one exception, is only what the writer and his assistants expected, provided the standards themselves were pure. The analytical methods employed and to be described yield results in experienced hands that are entirely in accordance with the above figures.

The abnormal result in the case of sodium carbonate ignited at a low red heat was investigated as follows:—

About 20 grms. of sodium carbonate were heated to constant weight at 572° F., and 10 grms. used for analysis of the standard acid showed it to contain 97.416 per cent. sulphuric acid. Ten grms. were placed in a platinum boat in a combustion tube, where it was heated to moderate red heat in a combustion furnace. A slow stream of dry air, free from carbon dioxide, was aspirated through the tube, and the carbon dioxide, disengaged by heating the sodium carbonate, was absorbed in a saturated solution of barium hydroxide, contained in a bottle. A Mohr bulb containing barium hydroxide was connected with the bottle and proved the complete absorption of carbon dioxide therein. After aspirating for several hours, the bulb was connected directly to the tube and the aspiration continued, which showed that no more carbon dioxide was evolved, no precipitate being formed.

The excess of barium hydroxide was neutralised with strong HCl, and finally carefully titrated with N/300 hydrochloric acid, using phenolphthalein as indicator; the barium carbonate was then titrated with N/300 hydrochloric acid, using Methyl Orange as indicator.

A blank titration was made using the same reagents, and the difference between the two Methyl Orange titrations represented the alkalinity due to barium carbonate. In this way 0.0060 grms. carbon dioxide were determined by a titration of about 35 c.c. of hydrochloric acid, thus making a simple and accurate determination.* The carbonate of soda that had been heated in the combustion tube was removed, accurately weighed, and used to analyse the standard acid. About 10 grms. were used, and the result obtained was 97.358 per cent., which is 0.058 per cent. lower than the result obtained above.

0.0060 grms. of carbon dioxide formed by decomposition of sodium carbonate would leave 0.0084 grms. Na₂O, which, when weighed and calculated as Na₂CO₃, would make a difference in the per cent. of sulphuric acid of 0.056 per cent., which agrees within 0.002 per cent. with the result found.

After heating to redness:—

9.9916 grms. Na ₂ CO ₃ are equivalent to	9.2369 grms. H ₂ SO ₄ .
0.0084 grms. Na ₂ CO ₃ are equivalent to	0.0134 " "
	9.2503 " "

Before heating to redness:—

10.0000 grms. Na ₂ CO ₃ are equivalent to	9.2447 " "
Increased alkalinity due to Na ₂ O formed	0.0056 " "

Equivalent to 0.056 per cent. of ..

If the CO₂ found had been the result of decomposition of sodium bicarbonate, the increased alkalinity would have been 0.078 per cent. instead of 0.058 per cent. found.

By heat:—

2NaHCO₃ = Na₂CO₃ + CO₂ + H₂O.
168.116 106.1 44 18.016
0.0060 grms. CO₂ found are equivalent to 0.0228 grms. Na₂CO₃.

After heating to redness:—

10.0 grms. Na₂CO₃ are equivalent to ... 9.2447 grms. H₂SO₄.

Before heating to redness:—

9.9772 grms. Na₂CO₃ are equivalent to 9.2236 grms.
0.0228 grms. NaHCO₃ are equivalent to 0.0133 "
9.2369 " 9.2369 "

Increased alkalinity due to formation ... 0.0078 "
of Na₂CO₃ from NaHCO₃ equivalent to 0.078 per cent. of

It is thus indicated by this experiment that the carbon dioxide formed is the result of decomposition of Na₂CO₃ into Na₂O + CO₂.

A sample of sodium carbonate, prepared by dry constant weight at 572° F., was heated until it had completely fused, and analysis showed an increased alkalinity equivalent to 0.30 per cent. of carbon dioxide disengaged.

If the calcium and magnesium carbonates present in the purified carbonate were entirely converted into calcium carbonate when ignited at low red heat only 0.018 per cent. increased alkalinity would be accounted for.

These results, considered together with the close agreement between the other standards and sodium carbonate ignited at 572° F., are very convincing arguments in favour of preparing standard sodium carbonate in this manner.

Standard Acid.—Averaging the results obtained from the different standards enumerated above, excepting sodium carbonate ignited to redness, its percentage composition was found to be 97.41 per cent. sulphuric acid.

This acid or its equivalent was used for standardising the caustic soda that was employed for all analytical determinations embraced in these tables.

The burette used was a 100 c.c. chamber bottle graduated from 95—100 c.c. in 1/10 c.c., and reliable to 1/100 c.c. The burette was standardised between 95 and 100 by weighing mercury delivered every 1/10 c.c., and for 1 c.c. the mercury was weighed every 1/10 c.c.; the readings and graduations were found to be accurate to 1/100 c.c. The burette was frequently cleaned with strong sulphuric acid, so that it drained perfectly for each determination.

Standard Sodium Hydroxide Solution.—This solution was prepared from C.P. caustic soda, purified by boiling, and was made of such strength that six grms. of standard acid required 95—98 c.c. Caustic soda purified by alcohol is not suitable for this purpose, as it does not drain properly in the burette, but produces a milky appearance. To standardise this solution, using Methyl Orange as indicator, about 6 grms. of the standard acid were quickly and accurately weighed out, diluted with about 400 c.c. cold distilled water and 1 c.c. of a 1/10 per cent. solution of Methyl Orange added. The caustic soda solution was then run in from the 100 c.c. chamber burette until a few tenths of a c.c. excess had been added, and after three minutes' draining the burette was washed. Standard sulphuric acid of strength about equivalent to the soda solution was added from a burette until a trace changed the colour of the solution from yellow to orange. The end point is sharper in titrating from alkaline to acid than *vice versa*.

H₂SO₄ taken — H₂SO₄ 2nd titration
c.c. NaOH = grms. of sulphuric acid

acid equivalent to 1 c.c. sodium hydroxide solution. A thermometer was kept in the standard solution and the temperature at which the solution was standardised was recorded, and in making a subsequent titration any other temperature the necessary correction applied to the reading. The correction for temperature was determined with the picnometer, as described above.

* This method was subsequently published in the "Analyst," May, 1904, vol. 29, pp. 152—153. Thos. Macara.

100 c.c. of solution was found to be 0.015 c.c. to be subtracted when the temperature was above temperature of standardising, and added when below. Duplicate titrations agreed within 0.03 c.c. Methyl orange was used in titrating nitric acid, hydrochloric acid and ammonia.

Standardise with phenolphthalein, about six grms. standard acid were accurately weighed out and into a casserole containing about 25 c.c. of cold dilute acid being rinsed from a small weighing beaker into the casserole. One c.c. of phenolphthalein solution (per litre) was added, and the sodium hydroxide solution run in from the 100 c.c. chamber burette until about 0.5 c.c. of the end point. The solution was boiled for five minutes to remove carbon dioxide, the titration finished by cutting the drops from the chamber burette until a fraction of a drop produced a pink colour. This tint was carefully noted, and the same run to the same end point. By boiling for five minutes, provision was made for uniformity of the burette. Duplicate titrations agreed within 0.02 c.c. The limits of burette reading were placed at 0.2 when Methyl Orange was used, and 0.02 c.c. for phenolphthalein, yet, as will be shown, the actual duplicate obtained by two men working independently agreed much closer.

Dividing Burette.—The dividing burette referred to in standardising with sulphuric anhydride is designed for dividing a solution. It consists of a burette of which is drawn to a capillary and bent down, the stopcock of the burette is a three-way cock, the passage being connected to a vertical tube at the top of which is a funnel for filling the burette. One and two flasks with small necks were graduated by running the burette a sufficient number of times to fill the flask to a point in the neck. This point was carefully marked, and in subsequent use, it was always filled to mark.

The amount of water delivered by the burette was 1.0, and the weights checked within 0.004 grms., or 10% of the weight of one burette full. In measuring the equivalent of 5 grms. of a liquid made up to volume, or would be 0.0002 grms.

The tables are described in the order in which they were used during a period of nearly three years.

NITRIC ACID TABLE.

C.P. nitric acid employed was free from nitrous and hydrochloric acids, and the residue upon evaporation at 212° F. was too small to affect the determinations. It was used for all samples up to 43° B., and for stronger samples this acid was concentrated by distilling with pure glacial phosphoric acid and potassium permanganate, the latter to prevent the formation of nitrous acid. 95-80 per cent. nitric acid was the strongest obtainable, for above this point the acid contained amounts of nitrous acid.

Sp. gr. determinations were made as described and at the same time the pycnometer was filled, 8 grm. sample was weighed in a small weighing bottle having a ground glass stopper, which prevented loss by weighing and diluting. The sample was diluted with water by removing the stopper of the tube with a fork while immersed in a casserole containing approximately 400 c.c. of water. The titration was then made using Methyl Orange as indicator, observing the same procedure as described in standardising.

Allowance for temperature.—After determining the sp. gr. of the different strengths employed at 60° F., the temperature was raised to 70° F., and the pycnometer refilled; likewise at 80° F. from this data the allowance for temperature was calculated, and was found to be 0.0001 for a given strength of acid. At 43° B. the determinations were made from 50° to 90° F.

Following determinations were made, and from the table was calculated by interpolation, the percentage composition being calculated to correspond with each 0.25° B.

From the Baumé the corresponding sp. gr. was calculated by the formula:— $B = 145 \frac{145}{\text{sp. gr.}}$

Sp. gr.	Per cent. HNO ₃	Sp. gr.	Per cent. HNO ₃
*1.0844	11.49	1.4506	77.15
*1.1095	18.45	1.4507	77.16
*1.1659	27.15	1.4563	78.78
*1.2109	33.80	1.4563	78.80
1.2641	41.77	1.4707	82.44
1.2643	41.81	1.4707	82.91
1.3144	49.69	1.4873	84.33
1.3144	49.70	1.4871	84.31
1.3761	60.45	1.4951	91.42
1.3760	60.44	1.4950	91.39
1.4469	76.57	1.4963	91.92
1.4471	76.57	1.4961	91.91
1.4405	74.84	1.5014	94.50
1.4404	74.80	1.5014	94.58
		1.5037	95.64
		1.5044	95.80

* These determinations are the average of results that checked within 0.0001 sp. gr. and 0.02 per cent., the record of which has been lost.

The instability of 96 per cent. nitric acid is so great that agreeing determinations were difficult to obtain, and those selected corresponded with the differential of the table at this point.

The following will show the comparative sensitiveness of the analytical determinations, sp. gr. determinations and reading of a delicate Baumé hydrometer and thermometer graduated to 1° F., in terms of sp. gr. :—

B.	Anal. Det.	Sp. gr. Det.	B. Reading 1/20°
15°	0.00013 sp.gr.	0.0001 sp. gr.	0.00044 sp. gr.
30°	0.00013 "	0.0001 "	0.00056 "
43°	0.00008 "	0.0001 "	0.00072 "

[Nitric Acid. See Table, p. 788.]

HYDROCHLORIC ACID TABLE.

The purest C.P. hydrochloric acid obtainable was tested for free chlorine, sulphuric acid and residue upon evaporation at 212° F. There were only traces of impurities, which would affect the determinations less than the errors of manipulation.

For the samples above 22° B. this acid was concentrated by distilling it into a portion cooled in ice water.

42.61 per cent. hydrochloric acid was the strongest sample upon which a sp. gr. determination could be obtained at 60° F. Above this point bubbles of gas were formed in the pycnometer when warmed to 60° F.

The sp. gr. and allowance for temperature were determined as in the case of nitric acid. The allowance for temperature was found to be uniform for each strength of acid; 22° B. determinations were made from 50° to 90° F.

After making the above determinations the thermometer of the pycnometer was withdrawn while the bottle was immersed in about 700 c.c. of water in a large casserole, thus avoiding loss while diluting. The bottle was carefully washed out and the dilute acid made up to two litres in a flask standardised against the 100 c.c., dividing burette and portions of this solution were taken with the burette for titration with sodium hydroxide. Methyl Orange was used as indicator, the same conditions used in standardising being closely followed, about 98 c.c. of sodium hydroxide solution being used for each determination. A sample of hydrochloric acid was analysed by precipitating with silver nitrate and the silver chloride

calculated to hydrochloric acid checked the results obtained by titration.

By silver chloride.	By titration.
29.97 per cent. HCl.	29.97 per cent. HCl.
29.98 per cent. HCl.	30.00 per cent. HCl.

The following determinations were made, and from these the table was calculated by interpolation, the sp. gr. and corresponding percentage composition being calculated for each 1° B. from 1°—5°, 0.25° B., from 5°—16° and for the rest of the table for each 0.1° B.

Sp. gr.	Per cent. HCl.	Sp. gr.	Per cent. HCl.
1.02813	5.73	1.13026	27.44
1.02815	5.73	1.13028	27.47
1.05353	10.74	1.15277	30.07
1.05359	10.73	1.15273	30.04
1.07676	15.37	1.16642	32.70
1.07678	15.37	1.16652	32.72
1.09670	19.29	1.19918	39.61
1.09664	19.28	1.19902	39.56
1.11440	22.73	1.20586	41.16
1.11442	22.76	1.20584	41.13
1.12360	24.35	1.21140	42.65
1.12360	24.37	1.21120	42.57

The following will show the comparative sensitiveness of the analytical determinations, sp. gr. determination and reading of a delicate Baumé hydrometer and thermometer graduated to 1° F. in terms of sp. gr. :—

[Hydrochloric Acid. See Table, p. 789.]

AMMONIA TABLE.

The ammonia was prepared from C.P. ammonia by distilling with lime into distilled water to free it from carbon dioxide and silica dissolved from the glass. 33.22 per cent. ammonia was the strongest sample upon which a sp. gr. determination could be made at 60° F. for above this point bubbles of gas were formed in the sp. gr. bottle when warmed to 60° F.

The sp. gr. and allowance for temperature were determined as in the preceding tables, but, on account of variation of the co-efficient of expansion at different temperatures for a given strength of ammonia, it was found necessary to make a determination for each 10° F. from 40°—100° F., and this was done in each case at 14°, 16°, 18°, 20°, 22° and 26° Baumé. At the same time the pycnometer was filled for the sp. gr. determination, a 6 to 8 grm. sample was taken in a weighed glass-stoppered weighing tube, on the stopper of which a little vaseline was placed to facilitate opening. After again weighing, the tube was introduced into a 16 oz. Erlenmeyer flask containing about 400 c.c. of water and an amount of standard sulphuric acid slightly in excess of that required for neutralisation. The flask was then stoppered and heated gently until the stopper of the tube had been expelled. Before removing the stopper from the flask, it was shaken and cooled so as to absorb all the ammonia. The titration was then finished by adding standard sodium hydroxide in slight excess and titrating back with standard sulphuric acid, using Methyl Orange as indicator and observing the same conditions as described in standardising.

The following determinations were made, and from these

the table was calculated by interpolation, the sp. gr. and the corresponding percentage composition being calculated for each 0.25° B. :—

From the Baumé the corresponding sp. gr. was calculated by the formula : $^{\circ}\text{B.} = \frac{140}{\text{sp.gr.}} - 130$.

Sp. gr.	Per cent. NH ₃
0.97880	5.07
0.97884	5.06
0.95954	10.12
0.95954	10.12
0.93950	15.68
0.93950	15.67
0.92050	21.77
0.92056	21.79
0.90420	27.11
0.90426	27.13
0.88630	33.22
0.88670	33.10

The following will show the comparative sensitiveness of the analytical determinations, sp. gr. determination and reading of a delicate Baumé hydrometer and thermometer graduated to 1° F. :—

29°	0.00006 "	0.00006	0.00014

[Aqua Ammonia. See Table, p. 787.]

SULPHURIC ACID TABLE.

The C.P. sulphuric acid used was 1.84 sp. gr., was free from hydrochloric and nitric acids and ammonia and gave a trace of residue upon evaporation. The impurities were less than enough to affect either the sp. gr. or analytical determinations.

The sp. gr. determinations were made as described above, except that in bringing the temperature to the pycnometer was immersed to the neck in a beaker of water a few degrees below 60° F., so that the temperature rose slowly, being the same inside and outside when capped.

The allowance for temperature for every 10° F. between 50° and 90° F. was determined at the following Baumé: 66, 63, 57, 51, 44, 36, 29, 21, 12. It was to be practically uniform for a given strength of acid, and the results are based on a range of 40° F., the corrections at even degrees Baumé being calculated from these results by interpolation. Samples were taken from the pycnometer for analysis, and an amount of acid was weighed out each time which would require between 95 and 100 c.c. of soda solution. With the weakest samples a more dilute standard soda solution was used, but the same conditions as used in standardising were observed in all cases.

The boiling point determinations were made in a 2 c.c. long-necked flask, using about 100 c.c. of acid in each case. A certified thermometer accurate to 1° F. was suspended in the acid. A small piece of porcelain was placed in the bottom of the flask to facilitate boiling. The flask was gradually heated with a free flame and the temperature recorded when boiling was first perceptible.

The following determinations were made, and from these the table was calculated by interpolation, the sp. gr. and the corresponding percentage composition being calculated for each degree Baumé from 0°—64° and each 1/4° B. from 64°—66° Bé.

From the Baumé the corresponding sp. gr. was calculated by the formula : $^{\circ}\text{B.} = 145 - \frac{145}{\text{sp.gr.}}$

The degree Twaddell was calculated by dividing the decimal part of the sp. gr. by 0.005.

Such merit as these tables possess is largely due to these gentlemen, but more especially to Mr. Bishop who had immediate charge of, and participated in most of the determinations, and who shared with the writer the preparation of this paper.

SPECIFICATIONS may be obtained by post by remitting as follows:—

English.—8d. each, to the Comptroller of the Patent Office, C. N. Dalton, Esq., Southampton Buildings, Chancery Lane, London, W.

United States.—1s. each, to the Secretary of the Society.

French.—1 fr. 25 c. each, to Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3^e).

PUMP, APPARATUS, AND MACHINERY.

ENGLISH PATENTS.

Generators; Means for Preventing Incrustation —. La Societe C. Bez et ses Fils, Paris. Eng. Pat. 10, June 2, 1904. Under Int. Conv. June 3, 1903.

Substances, such as those described in Eng. Pat. 1902 (this J., 1903, 942), are added to the feed so that the latter has a sp. gr. of, at least, 2° Baume. Acting as disin crustants, the added salts increase efficiency of the boiler.—W. P. S.

Impts. in the Removal of Precipitates from —. Sulman and H. F. Kirkpatrick-Picard, London. Pat. 13,481, June 14, 1904.

For rapid collection and filtration of finely divided precipitates is the object of this invention. From 1 per cent. of an alkaline soap is added to the liquid in which the finely divided precipitate is suspended, thoroughly dissolved in and mixed with it. An infinitesimal small proportion of a salt of calcium or magnesium, or other metal capable of forming an insoluble soap, is then added. The insoluble soap formed, envelopes and attracts the particles of the precipitate into a coagulum, which sinks rapidly to the bottom of the tank and can then be removed for further treatment. If the solution already contain a salt capable of forming an insoluble soap, the addition of the salt of calcium or other metal may be omitted.—W. H. C.

Motor and Filter for Mixed Liquids [e.g., Oil and Water]; An Improved —. H. G. Small and The Motionless Engine Packing Co., Ltd., Manchester. Pat. 17,625, Aug. 13, 1904.

The apparatus consists of a casing *a*, divided into three compartments, *b*, *c*, *d*. The mixture, oil and water, for instance, enters by the pipe *m* and passes through the partition *n*, *n*, where any coarse materials are kept back; it then flows down the funnel-shaped partition *e* and the water enters the bottom or "gravity settling compartment" *d*. Here the oil and water separate, the former rising upwards through the sieves *f*, *f*₁, *f*₂ of progressively increasing fineness of mesh, into the storage compartment *c*, provided with the gauge *j* and the draw-off

tap *h*. The water escapes by the opening *r* into the pipe *l*, through which it flows away in the direction shown by the arrows.—W. H. C.

Separating Liquids from Vapours; Apparatus for — J. McNeil, Govan. Eng. Pat. 4332, March 2, 1905.

The vapour enters the separator A (see Fig.) by the pipe

C, and owing to its decrease of velocity, deposits much of the liquid carried by it upon the walls of the lower portion of A and upon the perforated plate K, through which the liquid flows into the reservoir G, and escapes by the pipe J through a steam-trap. The vapour travels upwards through the truncated cone D, and passes out of the top with a "swirling motion," depositing the remainder of the liquid upon the perforated screen F and the cover B, and finally escapes through the pipe E, which is placed "diametrically" opposite the lower side of the apex of D. The liquid trickles down the walls and reaches the reservoir G by openings, one of which is shown at N.

—W. H. C.

Dashers; Impts. in — M. Murphy, New York. Eng. Pat. 5245, March 13, 1905.

THE claim is for a dasher constructed as shown in the plan (see Fig.) with the object of providing a number of vertical edges and recesses. The wings 2, 2, as well as the central portion 1, are horizontally perforated as indicated by the dotted lines.—W. H. C.

Cooling or Evaporating Liquids; Apparatus for — H. E. Newton, London. From H. R. Wertheim, New York. Eng. Pat. 7468, April 8, 1905.

THE invention relates to absorption towers, in which air is forced upwards. Claim is made for a reservoir into which the bottom of the tower is submerged, the level of liquid contained in it, can be varied, when working with forced draught, the bottom of the tower is sealed, whilst when using natural draught it is open to the atmosphere.—W. H. C.

FRENCH PATENT.

Air [and other Gases]; Process of Drying — J. C. Fr. Pat. 350,927, Jan. 21, 1905.

SEE Eng. Pat. 25,213 of 1904; this J., 1905, 539.—J. B.

II.—FUEL, GAS, AND LIGHT.

Formaldehyde and Acetaldehyde; Thermal Decomposition of — W. A. Bone and H. L. Smith. Chem. Soc. Trans., 1905, 87, 910—916.

THE vapour of the aldehyde was passed through a glazed porcelain tube heated to the desired temperature, the variation of the pressure during the test being observed by means of a manometer, and the nature of the decomposition-products determined.

Formaldehyde.—Experiments were made at 400°, 700°, 900° and 1125° C. In all cases the formaldehyde was decomposed mainly into carbon monoxide and hydrogen, but small quantities of a saturated carbon and carbon dioxide were always formed. The reaction was found not to be reversible to any appreciable extent under the conditions of the experiments. Then formaldehyde vapour was heated at 350° C. in horizontal glass bulbs, or passed slowly over a hot surface of porcelain, more complex reactions took place, a number of intermediate products were formed. The gases produced consisted mainly of carbon monoxide and hydrogen, but the ratio CO/H₂ was high and variable.

Acetaldehyde.—Experiments were made at 400° and 800° C. At 400° C. the aldehyde decomposed according to the equation: CH₃.CHO = CH₄ + CO, but at 800° C. carbon and hydrogen were also produced, and at a small quantity of acetylene. Acetaldehyde vapour heated at 350° C. under atmospheric pressure, in horizontal glass bulbs, decomposed into methane and carbon monoxide, without any separation of carbon or liberation of hydrogen. In contact with porous porcelain at 500—500° C., acetaldehyde decomposed into carbon monoxide and methane, and unsaturated hydrocarbons (ethylene, &c.) and aldehydes (crotonaldehyde).

It is pointed out that in combustion phenomena when the aldehyde is always rapidly decomposed or burnt by oxygen, the more complex changes could hardly be a prominent part; the aldehydes would either be completely burnt by the oxygen, or would undergo complete decomposition, formaldehyde into carbon monoxide and hydrogen, and acetaldehyde into carbon monoxide and methane.—A. S.

Formaldehyde; Synthesis of — D. L. Chapman and A. Holt, jun. Chem. Soc. Trans., 1905, 87, 91—121.

THE authors have succeeded in synthesising formaldehyde from mixtures of (a) carbon monoxide and hydrogen; (b) carbon monoxide, hydrogen and steam; (c) carbon monoxide and steam; (d) carbon dioxide and hydrogen. The gaseous mixtures were heated in a large glass globe by means of a platinum wire through which an electric current was passed. Experiments in which the gases were passed through tubes heated at temperature 500° C. gave negative results. Only traces of formaldehyde were produced from a mixture of equal volumes of carbon monoxide and hydrogen, saturated with vapour at the ordinary temperature, but by suspending a test-tube containing water in the globe immediately above the heated platinum wire, so that the water

CURRENTS of cooled products of combustion, and of a

mixture of steam and air, in predetermined proportions, are drawn alternately through a deep layer of incandescent fuel, whereby combustible gas is produced, whilst at the same time the gas-product is cooled below the clinkering point of the fuel.—R. L.

FRENCH PATENTS.

Briquettes Manufactured from a Binding Material — Schuler in Wien. R. Wagner. Fr. Pat. 350,579, Jan. 7, 1905.

A MATERIAL suitable for briquette making can be obtained by heating separately the chief constituents, for instance, anthracite, at about 140° C., and the binding material, which may consist of the residues from the above manufacture, at about 600° C. The materials are then mixed in a triturating trough, at a temperature of about 100° C., and pressed.—R. L.

Coal Drying of Small — Maschenbau-Anstalt Humboldt. Fr. Pat. 350,789, Jan. 16, 1905.

THE "small" and impurities delivered from a washing apparatus along with water, are collected in two hoppers by which they are distributed on to a belt conveyor, and are carried to drying towers. By a suitable arrangement of rollers this conveyor keeps the material continually agitated, clogging thus being avoided. The impurities which are not deposited on the conveyor are carried off by the water into a further collecting hopper, where they settle, and are conveyed back to the first hopper-collecting arrangement, whilst the clear water on the top is drawn off by an overflow, and used again in the washing apparatus. It is claimed that a homogeneous material is obtained.—R. L.

Combustible Process of Making — from Refuse Sweepings. E. C. May. Fr. Pat. 350,823, Jan. 17, 1905.

THE sweepings, after being sorted to get rid of pieces of metal and broken earthenware, &c., are mixed with about 3 per cent. of a disinfectant, composed of equal parts of quicklime and ammonium salts. The mixture is ground, dried, and partially carbonised, and then mixed with about 6 per cent. of crude petroleum, and about 5 per cent. of lime, and formed into briquettes.—W. H. C.

Coke Method for the Production of — by the Employment of Materials containing Metallic Oxides. In. C. Otto and Co. Fr. Pat. 351,007, Jan. 25, 1905.

IN the method of producing coke, in which the coal, before being carbonised, is mixed with bodies containing metallic oxides, such as the dust from blast-furnace gases, burnt pyrites, &c., the yield of ammonia is low, owing to the action of the oxygen of the metallic oxides. This loss is claimed to be prevented by reducing the oxides to the metallic state before mixing with the coal.—W. H. C.

Gas from Tar and Analogous Substances: Process and Apparatus for making Combustible — C. Whitfield. Fr. Pat. 350,967, Jan. 23, 1905. Under Int. Conv., Jan. 23, 1904.

SEE Eng. Pat. 1738 of 1904; this J., 1905, 490.—T. F. B.

Gas: Apparatus for the Purification of Blast Furnace — L. Schwarz and Co. Fr. Pat. 350,992, Jan. 7, 1905.

THE apparatus consists of a conical shell in which a conical drum revolves horizontally. The gas enters at the narrower end of the apparatus and before arriving in the annular space between the two cones, passes a system of circular discs, which are fitted vertically on the revolving axle, and are constantly kept moist. These discs are fitted close together so that the water forms annular films which have to be penetrated by the gas. The inner drum is provided on its outside with blades which almost touch the conical vessel. The drum revolving at high speed acts like a ventilating fan, and whilst causing a centrifugal motion of the gas offers only slight resistance to its passage through the apparatus. The dust contained in the gas being charged with moisture, is deposited on the walls of the apparatus, and can be removed through a manhole. The gas leaving the apparatus is passed through a drying arrangement.—R. L.

GERMAN PATENT.

Gas Retorts: Device for Sealing the Ascension Pipe against the Hydraulic Main. M. Hempel. Pat. 158,374, Dec. 16, 1903.

By means of the device claimed, the ascension pipe

sealed against the hydraulic main, without the use of an ordinary water-seal, whilst when the retorts are being worked, communication is opened between the ascension pipe and the outer air. A fixed cylinder interposed between the ascension pipe *d* and the hydraulic main, and within this is another cylinder *b*, which is movable vertically, and is divided into two compartments by the partition *c*. When the inner cylinder is in its position, the partition abuts against the raised rim *e* of an outlet in the bottom of the fixed cylinder, and cuts off communication between the ascension pipe and the hydraulic main, whilst at the same time, the pipe *f* in the cover of the fixed cylinder, is opened to the outer air. When the movable cylinder is raised, on the other hand, communication between the ascension pipe and the hydraulic main is opened, whilst the outlet to the outer air is sealed. Claim is also made for a retort-ring *m* in the lower end of the movable cylinder which is for the purpose of preventing spitting of water-seal is in use, see Fig. 2).—A. S.

Hydrocarbons of the Benzene Series: Electrodynic Treatment of — 11. Ethyl-benzene, Cumene and Cymene. H. Law and F. M. Perkin. XI.4., page 805.

UNITED STATES PATENT.

Petroleum: Process of Separating Sulphur-containing Constituents of — and of separating Hydrogen Carbide. H. S. Blackmore, Mount Vernon, Assignor to Blackmore Ford Utility Oil Co., Columbus, Ohio. U.S. Pat. 793,026, June 20, 1905.

SEE Fr. Pat. 346,275 of 1904; this J., 1905, 127.—T. F. B.

FRENCH PATENT.

Tar [from Tar and Mineral Oils]: Manufacture of Stable and Non-Eructile — A. Coupré and P. Blas. Fr. Pat. 350,834, Jan. 18, 1905. IX., page 802.

GERMAN PATENT.

Lubricants which form Stable Emulsions with Water: Process of Preparing — V. Urbanek. G. Pat. 159,526, March 3, 1903.

VASILINE oil is treated with air in the usual manner

sed with about 20 per cent. of wool fat; the mixture is stated to form emulsions with water.—T. F. B.

—COLOURING MATTERS AND DYESTUFFS.

ines and Aminoazo-compounds. I. The Influence of the Substitution on the Formation of —. III. and IV. by Morgan, W. O. Wootton and A. Clayton. Chem. Trans., 1905, 87, 935—951.

Derivatives of Symmetrically Disubstituted Primary Amines.—It has been shown previously (Chem. Soc. Trans., 1902, 81, 86) that by the action of a diazonium salt on an aromatic meta-diamine, in which the two para to the amino-groups are occupied by two groups, by one methyl group and one chlorine, or by two chlorine atoms, an orthoazo-compound is formed, although in smaller yield and less readily than when the condensation is effected with an isomer, having a free para-position with respect to one of the amino-groups. Also, bases having a free para-position give brownish-brown shades on cotton impregnated with diazo-Primuline, whereas the symmetrical disubstituted bases give yellowish-brown shades. Experiments have been carried out with meta-dianilines in which the amino-groups were nitro-groups or bromine or iodine. 4,6-Dibromo-*m*-phenylenediamine was prepared by heating diacetyl-*m*-phenylenediamine, and hydrolysing the acetyl bromo-compound with alcoholic potassium hydroxide. The di-iodo-compound was obtained by heating an aqueous solution of *m*-phenylenediamine with an alcoholic solution of iodine, in the presence of sodium acetate. The dibromo- and di-iodo-compounds behave like the dichloro-compound with diazo-salts, giving indefinite uncrystallisable products with *l*-phenylene-*p*-diazonium chloride, but crystallisable products with *p*-nitrobenzenediazonium chloride. The shade produced by treating cotton impregnated with diazotised Primuline, with the three dihalo-dianilines deepens considerably as the atomic weight of the halogen increases. The readiness with which azo-compounds are formed, appears to be greatly influenced by the presence of nitro-groups in the molecule of the diazonium salt, and experiments with 5-nitro-2,4-diaminotoluene and with 6-chloro- and 6-bromo-4-nitrophenylenediamine, showed that the nitro group exerts a marked influence when present in the diamine nucleus. The last-named bases both yield ingrain colours with diazo-Primuline.

*Di-*o*-*o*-(4)-dimethyl-2,4-diaminotoluene.* Tetra-4,6-diamino-*m*-xylene does not condense with diazo-salts, this inactivity being due to the presence of substituents in the two para-positions with respect to the amino-groups, since when one of these positions is free, as in the case of the lower homologue, tetra-2,4-diaminotoluene, the production of the azo compound takes place readily and quantitatively (Soc. Trans., 1902, 81, 659). Dipara-substituted meta-dianilines still give azo-derivatives, although less readily than those dianilines containing one free para-position (Chem. Soc. Trans., 1902, 81, 89), and, in order to determine how far the alkylation of a dipara-substituted meta-diamine may proceed before the production of azo-derivatives with diazo compounds is quite inhibited, the authors studied the behaviour of 5-bromo-*o*-*o*-(4)-dimethylaminotoluene. This bromo-derivative, when treated with a diazonium salt of *p*-nitraniline or *p*-bromaniline, yields a diazobenzenesulphonic acid, yields an ill-defined crystallisable product, which gives the reactions both of an azoamine and of an aminoazo-compound. With diazo-Primuline on cotton, 5-bromo-*o*-*o*-(4)-dimethylaminotoluene, like 5-bromo-2,4-diaminotoluene gives a reddish-red azo-colour of somewhat duller shade than that produced with *o*-*o*-(4)-dimethyl-2,4-diaminotoluene.—A. S.

(U.S. Pat. 811, 111, 112, 113, 114, 115, 116, 117, 118, 119, 120, 121, 122, 123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000.

Dyes [Sulphide Dyestuffs]. Manufacture of Sulphine and of Material for the Preparation of Sulphine. London: Frank & Sons, Ltd., 1904. Eng. Pat. 17,318, Aug. 5, 1904.

INDOPHENOLS of the formula $\text{C}_6\text{H}_4\text{N}(\text{R}_1)(\text{R}_2)$, in which R_1 and R_2 are aromatic radicals of the benzene or naphthalene series, are obtained from acetylhydrazine, $\text{R}_1\text{NH}(\text{CH}_3)\text{COCH}_3$, and a monosulphonic acid of an aromatic radical, $\text{R}_2\text{NH}(\text{SO}_3\text{H})$, either by oxidising them in an aqueous solution with potassium phenols or by reacting upon them with potassium phenols in the presence of concentrated hydrochloric acid, and then with a somewhat diluted sulphuric acid. These compounds are then converted into sulphide dyestuffs by heating with a solution of cotton in bluish-violet to blue-tan shades, or with a solution of cotton, or their leuco-compounds, with a solution of cotton in boiling aqueous or alkaline solution, and the leuco-compounds are removed from the above in higher yields by precipitating and dissolving them in an aqueous solution of sodium carbonate, and precipitating with sodium carbonate. For example, 10.5 parts of *o*-toluidyl-*o*-ne and 11 parts of p-aminophenol are dissolved in 150 parts of water and 21 parts of concentrated sulphuric acid. A concentrated aqueous solution of 20 parts of sodium bicarbonate is then added with stirring, and the indophenol precipitated with sodium acetate. It is preferably reduced to the leuco-compound as described above, before conversion into a sulphide dyestuff. One part of this leuco-compound is then heated for 24 hours under a reflux condenser with four parts of crystalline sodium sulphide, two parts of sulphur and four parts of water. The mass is then diluted and the dyestuff precipitated by a current of air. It dyes cotton from a sodium sulphide bath in deep blue shades of good fastness. The indophenol from *o*-naphthylglycine and *p*-aminophenol dissolves in aqueous sodium hydroxide solution with an intense Bordeaux-red colour.—E. F.

Colours [Sulphide Dyestuffs]. Manufacture of Sulphine —. R. B. Ransford, Upper Norwood, Surrey. From Leopold Cassella & Co., Frankfurt-on-the-Main, Germany. Eng. Pat. 17,318, Aug. 5, 1904.

THE sulphide dyestuffs obtained by heating *p*-*p*-dihydroxydiphenylamine and analogous bodies with polysulphides are treated with oxidising agents in an alkaline solution. In this way, new blue dyestuffs are obtained, distinguished by easy solubility, level dyeing, and fastness to washing, light and chlorine. The simplest manner of producing the primary dyestuffs is to boil the indophenol obtained by simultaneous oxidation of *p*-aminophenol, amino-*o*-cresol [$\text{OH}(\text{CH}_3)\text{NH}_2 = 1:2:4$], or *p*-amino-*o*-chlorophenol [$\text{OH}(\text{Cl})\text{NH}_2 = 1:2:4$] on the one hand, and phenol, *o*-cresol, *m*-cresol, *p*-xylenol [$\text{CH}_3(\text{CH}_3\text{OH}) = 1:4:2$], or *o*-chlorophenol on the other hand, or their products of reduction, together with polysulphides in a concentrated solution. The primary dyestuffs may also be obtained by directly heating the dihydroxydiphenylamines with sulphur only. The oxidation must take place in alkaline solution. It is most quickly effected with hydrogen peroxide or sodium peroxide at a medium temperature. It may also be very successfully effected by means of the potassium oxydant, also by blowing a current of air into the solution at 70° C. to 100° C. by potassium ferricyanide or by hypochlorites. For instance, 50 kilos. of the dyestuff obtained by heating 200 kilos. of indophenol from *p*-aminophenol and phenol, 240 kilos. of sodium sulphide, 120 kilos. of sulphur, and 1100 litres of water for 20 hours are dissolved in 5000 litres of sodium hydroxide solution of 40° B. and about 500 litres of water at 15° C., and 25 kilos. of sodium peroxide are carefully and gradually added. The temperature rises to 60° C., and the greenish-blue colour of the solution changes to a deep reddish-blue. The excess of alkali is then neutralised with hydrochloric acid, and the dyestuff precipitated with salt. It dyes cotton in indigo-blue shades from a sodium sulphide bath. Homologous and chlorinated indophenols yield final products of more reddish shades.—E. F.

Colouring Matters: Manufacture of Azo — and of Intermediate Products relating thereto. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 19,165, Sept. 5, 1904.

SEE Fr. Pat. 346,007 of 1904; this J., 1905, 84.—T. F. B.

Indoxyl, its Homologues or their Derivatives: Manufacture of —. O. Imray, London. From the Basle Chemical Works, Basle, Switzerland, Eng. Pat. 19,474, Sept. 9, 1904.

SEE U.S. Pat. 776,884 of 1904; this J., 1905, 23.—T. F. B.

Dyes [Azo Dye-stuffs]: Production of Blue Mono-azo —. H. B. Lake, London. From K. Oehler, Offenbach-on-the-Maine, Germany. Eng. Pat. 7839, April 12, 1905.

6-NITRO-2-AMINOPHENOL-4-SULPHONIC acid is diazotised and combined with β -hydroxynaphthoic acid of m.p. 216° C. The product dyes wool in indigo blue shades, which are weakened by chroming. The dyeings are unchanged by artificial light and interwoven cotton remains absolutely white on dyeing.—E. F.

UNITED STATES PATENT.

Dye-stuff; Reddish Azo —. K. Krekeler, Elberfeld, Germany, and A. Blank, Leverkusen, Germany. Assignors to Farbenfabriken of Elberfeld Co., New York, U.S.A. U.S. Pat. 792,600, June 20, 1905.

DLAZO-COMPOUNDS are combined with certain naphthimidazoles. The products dye unmordanted cotton in red to reddish-blue shades. The dye-stuff prepared by combining the diazo-derivative from *o*-toluidine with *m*-amino-1,2-naphthimidazole-5-hydroxy-7-sulphonic acid is specially claimed. It dyes unmordanted cotton in red shades which can be further diazotised on the fibre, and then developed by β -naphthol. Pure red shades are thus obtained, fast to washing and to light.—E. F.

FRENCH PATENTS.

Dye-stuffs of the Anthracene Series; Production of a New Series of Derivatives and —, and their Application in Dyeing and Printing. Badische Anilin und Soda Fabrik. Fr. Pat. 349,531, Dec. 21, 1904. Under Int. Conv., March 25, and Aug. 12, 1904.

SEE U.S. Pat. 786,085 of 1905; this J., 1905, 494.—T. F. B.

Quinizarin; Process of Manufacture of —. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 350,957, Jan. 23, 1905.

QUINIZARIN is obtained by heating erythrohydroxyanthraquinone with nitrous acid or its derivatives in sulphuric acid solution. The addition of boric acid is advantageous. For example, 20 kilos. of sodium nitrite and 30 kilos. of crystallised boric acid are dissolved in 600 kilos. of sulphuric acid of 66° B. 30 kilos. of erythrohydroxyanthraquinone are then added and the mixture heated to 180° – 200° C.—E. F.

GERMAN PATENTS.

1-Hydroxyanthraquinone-5-sulphonic Acid [Anthracene Dye-stuff]; Process of Preparing —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 158,413, May 3, 1903.

By heating anthraquinone-1-sulphonic acid with fuming sulphuric acid containing less than 40 per cent. of sulphuric anhydride, at temperatures above 100° C., it is converted into 1-hydroxyanthraquinone-5-sulphonic acid. This latter is converted into Anthranilin by heating with milk of lime under pressure.—T. F. B.

**o*-Nitrotoluene; Method of Purifying —.* Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat. 158,219, Nov. 8, 1903.

**o*-NITROTOLUENE* may be purified by cooling the crude substance to between -4° and -10° C., allowing it to partly crystallise at that temperature, and then separating the

crystals from the mother liquor. The product thus obtained is stated to differ materially from that produced by cooling to below the solidifying point of *o*-toluene, -10.5° C.—T. F. B.

Dye-stuff; Method of Preparing a Yellow Mono-azo —. Farbwerke vorm. Meister, Lucius und Brüning. Ger. Pat., 160,040, April 20, 1904. Addition to Ger. Pat. 158,148, Feb. 14, 1904.

INSTEAD of using *o*-aminosalicylic acid as in the previous patent (see this J., 1905, 542), *o*-aminophenolsulphonic acids and their substitution products are diazotised combined with β -diketones in alkaline solutions. The dye-stuffs produce greenish-yellow to red shades; copper lakes are brownish-yellow to brown, and chromium lakes orange to brown. The dye is faster to rubbing than those produced by the dye of the original patent. The following amino compounds may be used:—2-aminophenolsulphonic acid, 2-aminophenol-4-sulphonic acid, 4-chloro- and 4-aminophenol-6-sulphonic acid, 3-amino-2-cresolsulphonic acid; and the following ketones:—Acetone, ester, acetylacetone, acetacetanilide, and benzoylacetone.—T. F. B.

Amines with Formaldehyde; Process for Preparing Condensation Products of Primary Aromatic Amines. Farbwerke vorm. Meister, Lucius und Brüning. Pat. 158,543, March 18, 1904.

THE salts of aromatic nitro-amino compounds condensed with formaldehyde in aqueous solution are products of the type $\text{CH}_2(\text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2)_2$, stated to be valuable for the production of lakes. Analogous products have hitherto only been obtainable by performing the condensation in alcoholic solution.—T. F. B.

**o*-Nitroanthraquinones and their Derivatives; Process of Replacing the Nitro Groups of — by Hydroxyl Groups [Anthracene Dye-stuffs].* Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 158,891, Sept. 8, 1903.

THE *o*-nitro groups of *o*-nitroanthraquinones or their derivatives may be replaced by hydroxyl groups by heating with alkaline-earth hydroxides. Sulphonate groups of *o*-nitroanthraquinones are also replaced by hydroxyl groups by this method. Thus Anthraquinone is obtained from 1,5-dinitroanthraquinone or from 1,8-nitroanthraquinone-sulphonic acid, and Erythroxyanthraquinone from anthraquinone- α -monosulphonic acid.—T. F. B.

1,8-Phenyl- or Tolylnaphthylaminesulphonic Acid; Process of Preparing —. Act.-Ges. f. Anilin- und Farbwerke. Ger. Pat. 158,923, Oct. 31, 1903.

WHEN 1,4,8-naphthylaminedisulphonic acid is heated with aniline or *p*-toluidine, with or without the hydrochloride of the base or benzoic acid, to a high temperature, the amino group is converted into an aliphylamino group and the sulphonyl group in the 4-position is replaced by hydroxyl, whilst the sulphonyl group in the 8-position remains unchanged; the result is that 1,8-phenyl- or -tolyl-naphthylaminesulphonic acid is produced. 1,4,8-naphthylaminedisulphonic acid is obtained by sulphonating naphthalene, nitrating, reducing, and separating the two naphthylaminedisulphonic acids.—T. F. B.

1,6- and 1,7-Phenyl- or Tolylnaphthylaminesulphonic Acids; Process of Preparing —. Act.-Ges. f. Anilin- und Farbwerke. Ger. Pat. 159,353, Sept. 14, 1904. Addition to Ger. Pat. 158,923 (see preceding abstract).}

By heating 1,4,6- or 1,4,7-naphthylaminedisulphonic acid to a high temperature with aniline or *p*-toluidine, with or without addition of benzoic acid or the hydrochloride of the base, 1,6- or 1,7-phenyl- or -tolyl-naphthylaminesulphonic acid is obtained.—T. F. B.

Quinophthalone and its Homologues; Process of Preparing Pure —. A. Eibner. Ger. Pat. 158,761, Dec. 31, 1903.

THE condensation products of quinaldine and its mono-

with phthalic anhydride are quantitatively converted into the sodium derivatives of quinophthalone, $\text{H}_2\text{C}_8\text{H}_4\text{O}_2$, and its homologues, by treatment with ethylate; the free quinophthalones are obtained from their sodium derivatives by boiling with water. The pure products are obtained in a very finely crystalline condition, are more soluble in water, and give shades, faster to light, than the commercial, spirit-soluble quinophthalones. The following homologues are mentioned: α -*p*-dimethylquinophthalone; α -*p*-trimethylquinophthalone; and β -naphthoquinophthalone.

—T. F. B.

methyl Derivatives of Aromatic Amines; Method of Preparing —. Badische Anilin und Soda Fabrik. At. 158,718, Jan. 9, 1904. Addition to Ger. Pat. 144,762, 1902.

DIMETHYLDIPHENYLAMINE is obtained by the reaction of a bisulphite and formaldehyde on diphenylamine. The product is converted into the ω -cyanomethyl derivative by treatment with a metallic cyanide. The latter takes place according to the equation:

—T. F. B.

Process of Preparing a Yellow Cotton Sulphide —. Badische Anilin und Soda Fabrik. Ger. Pat. 1, March 9, 1904. Addition to Ger. Pat. 144,762, 1902.

POLYTHIOUREA, produced by heating to 100° C., a mixture of *m*-toluylenediamine and a thiocyanate, is dyed with benzidine and sulphur. The resulting dyes give clear greenish-yellow shades on cotton.

—T. F. B.

REPAIRING, BLEACHING, DYEING, FINISHING, AND FINISHING TEXTILES, YARNS, AND FIBRES.

Applications of Copper Sulphate in —. *Textile Engineering*. Rev. Gen. Mat. Col., 1905, 9, 185—187.

A new method of treating yarn dyed with azo dyestuffs with copper sulphate is to pass it, after dyeing, through a hot bath containing 2 to 3 per cent. of copper sulphate, calculated on the weight of dyed yarn. In this case the alkali and alkali salts retained in the fibre from the preceding processes are utilised to react with the copper sulphate, and the method is very simple, as much of the copper is not permanently fixed. The process employs the same quantity of copper, which is only fixed by subsequent treatment with sodium hydroxide solution. After dyeing with a direct colour, diazotising and developing on the fibre, the cotton yarn is run out. A solution of 3 kilos. of copper sulphate in 50 litres of water has been meanwhile prepared. One end of the cotton is then treated with a mixture of 6 litres of this solution with 6 litres of water. Before treatment with the second kilo. of cotton, half a litre of the copper sulphate solution is added to the bath. 100 kilos. of goods require 56 litres of copper sulphate solution. The goods are then passed, in a similar manner, through a sodium hydroxide solution. 3 kilos. of sodium hydroxide in 57 litres of water. The initial bath is made up of 6 litres of this solution and 6 litres of water. After passing each kilo. of cotton, a further half litre of the sodium hydroxide solution is added. The goods are then washed well. If, for instance, the cheapest and most common azo-black, namely, Diazo Black B11N—(Elberfeld) is used, and subsequently treated as described, it will not fade or change appreciably if exposed to the weather for two years. Moreover, the goods lose in weight if treated in this way, whereas, when dyed with azo-blacks and other dyestuffs, they lose 4 to 5 per cent. In the case of mercerised goods, a sodium hydroxide bath is not necessary. The copper treatment rather helps than impairs the effect of mercerisation.

Piece goods may be treated in a similar manner to hanks. In diazotising on the piece, goods of direct sunlight should be carefully protected. The Black B11N, which has been treated with copper sulphate, possesses the property, in common with Azoblack B11N, of being deepened by treatment with glue, giving a deep black. The following uses of copper sulphate are mentioned:—(a) In conjunction with dyewood extracts, such as Persian berries, fustic and log-wood; (b) in conjunction with subsequent treatment with sodium hydroxide, yielding a fast sea-green shade; (c) mixed with potassium permanganate, with subsequent treatment with sodium hydroxide, yielding lilac, olive, and bronze shades; (d) or mixed with iron sulphate, dried and passed through sodium hydroxide solution, to give khaki shades, fast to chlorine air and caustic alkali. Copper also is still one of the best oxidising agents for producing Aniline Black on the fibre. It is also used as a preservative, for instance, in conjunction with alum, for preventing bacterial decomposition of orchil extracts. Subsequent treatment with copper sulphate is not advisable in the case of Primuline dyestuffs, as the fastness is not improved whilst the shade is injured. Cobalt and nickel sulphates may often be used, instead of copper sulphate, especially with Poirier's Thioeatechines.—E. F.

Reserves under Alizarin Colours; Phosphoric Acid and its Salts as —. L. Specht and A. Hutschek. *Z. Farben-u. Textil-Ind.* 1905, 4, 297—298.

RESERVES consisting of phosphoric acid and its salts thickened with gum were printed on oiled cotton cloth in different degrees of concentration and treated with an alizarin "for pink" printing paste, containing 7 grms. of alizarin per litre, steamed for 1½ hours under pressure, soaped and washed. The best effects were obtained with sodium metaphosphate, ammonium phosphate, mono-sodium-dihydrogen phosphate and sodium pyrophosphate. As regards economy di-ammonium-hydrogen phosphate is the most suitable salt. For the production of white discharges, tissues mordanted with alumina are printed with phosphate resists and thereupon dyed with alizarin. The results are as effective as those obtained with organic acids as discharging agents, such as tartaric, citric, and oxalic acids and the like. Although phosphates are used with advantage as precipitants for aluminium mordants, their function as colour resists appears to be due to the solubility of the resulting aluminium phosphate in an excess of fixing agent. Phosphate reserves combine readily with direct dyestuffs and can be used in conjunction therewith as coloured discharges to form pleasing designs. Arsenic and silicic acids and their salts act in a similar manner.—D. B.

Sulphur Dyestuffs; Fixing — by the aid of Sodium Hydro-sulphite-Formaldehyde [*Calico Printing*]. C. Favre. *Bull. Soc. Ind. Mulhouse*, 1905, 75, 104—109.

A black colour is obtained upon cotton tissues from a mixture of Immedial Black V "in paste" (½ litre) and caustic soda-lye (¾ litre at 50° B.), which are stirred together and then left at the ordinary temperature for a few hours before being thickened with a solution of British gum (¾ litre), a small quantity of sodium hydro-sulphite-formaldehyde being also added to prevent the mixture from blackening the copper printing-rollers. The tissues printed with this mixture, after being steamed for two minutes in a strong current of steam, are passed at full width, for one minute, into a bath of hydrochloric acid and copper sulphate (2 litres of the concentrated hydrochloric acid with 200 grms. of copper sulphate in 100 litres of water); at a temperature of 44° C. After being washed and soaped in the rope state, they are next treated with copper nitrate (2 kilos. in 100 litres of water). The last operation greatly increases the fastness of the dyestuff to bleaching powder, and renders the black colour, which is of a good, deep shade, extremely fast to soap and light. The dyestuff in the form of paste is recommended as giving a better yield of colour than the product which is supplied under the same name in the state of powder.

Grey colours are produced by reducing the black

see Figs.) extending at right angles from movable arms, in conjunction with reels *a*, for the reception of yarns, more particularly those consisting of the bars *c*, as they move, are guided between the bars *c*, carried by rails *s*, *s*¹, of which the rail *s*¹ is pivoted at its ends to the arms *c*¹, rocking upon pins *d*, projecting from the frame. A reciprocating motion is given to the rods *b* by an eccentric *o*, actuated by a shaft *u*, an arm *p* being eccentrically engaging with a pin *r* on one of the arms *c*. The rail *s* is guided on fixed pillars *l* and is suspended by cords *t* carried over pulleys *l* on shafts *u*, *u*¹, *v*, *v*¹, mounted on a shaft *x* provided with a hand-wheel *y*.

The rail *s* is provided with tappets *m* which are engaged to engage with corresponding tappets on the gear wheels *e* are fixed upon the shaft *x*, with racks *z* on the pillars *l*. The reels *a* upon which the skeins are spread are mounted on a frame *q* which can be moved up and down the pillars *l*. On the hand-wheel *y* in one direction, the reels *a* and the frame *q* are raised. But the latter being lifted less than the former, the two rows approach each other. The operation of the dyed skeins and the placing in position of the dyed skeins is thus facilitated. As the only pressure upon the skeins during the operation of dyeing is the weight of the dyed skeins and bars, and as this is a yielding one, rupture of the skeins during this operation is avoided.—E. B.

Mechanism for —, wherein the Material to be dyed is continuously submerged within the Dye Bath Exposure to the Atmosphere during the Dyeing Process. J. R. Greenwood, Upper Chichester, U.S.A. Pat. 2873, Feb. 11, 1905. Under Int. Conv., 12, 1904.

Pat. 776,237 of 1904; this J., 1905, 25.—T. F. B.

and other Woven Fabrics; Impts. in Printing —, H. Hulme, Didsbury. Eng. Pat. 16,798, July 30, 1904.

Effect of this invention, which is an improvement on the subject of Eng. Pat. 1799 of 1891 (1892, 160), is to enable a discharge pattern and a pattern in Indigo or other dyestuff to be produced on the same passage through the apparatus, and the tissue is passed successively (i) over a "roller" revolving in a discharge solution; (ii) down over guide rollers in the air; (iii) over a "pattern roller," by means of which Indigo or other dyestuff is applied; (iv) over guide rollers; (v) into a bath where it is sprayed upon or otherwise washed with a suitable solution, and thence (vi) into a bath where the washing is completed.—E. B.

Printing Pastes for the Discharge of Dyed Textile Fabrics; Manufacture of —, J. Y. Johnson, London. Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 20,178, Sept. 19, 1904.

Second Addition, dated Sept. 17, 1904, to Fr. Pat. of 1900; this J., 1905, 130.—T. F. B.

Apparatus for Evaporating the Liquid in Brewers' Wash, or Waste or Spent Dyes and the like, and Concentrating the Solids in the same, the Evaporator being also applicable as a Smoke Washer. A. B. Lennox. Eng. Pat. 3,227, June 11, 1904. XVIII.B., page 811.

UNITED STATES PATENTS.

Method of Making Artificial —, H. S. Mork, Walker and A. D. Little, Boston, Mass., U.S.A. Pat. 792,149, June 13, 1905.

A solution of a low volatile ester, such as cellulose acetate, is dissolved in a suitable mixture of a compound of high volatility. A compound of low volatility, a small proportion of a volatile compound being also added to the solution. The solution is projected through minute holes (in a draw) to a coagulating compound, a number of the filaments produced being twisted together, and wound under tension, to form threads of artificial silk.—E. B.

Viscose; Manufacturing Filaments From —, C. A. Ernst, Lansdowne, Pa., U.S.A. U.S. Pat. 792,888, June 20, 1905.

FILAMENTS prepared from a solution of viscose are passed into a bath containing an inert organic reagent, e.g., alcohol, spirit; an organic acid, e.g., acetic acid; and a salt soluble in the acid employed, e.g., sodium acetate, in order to set them. They may be afterwards immersed in a bath of an inert organic reagent and an acid, to "revert" the viscose.—E. B.

Dyeing Machine. M. Sarfert, Philadelphia, Pa., U.S.A. U.S. Pat. 786,162, March 28, 1905.

THE apparatus which forms the subject of this invention consists of an annular trough 2 (see Fig.), supported by friction rollers 10, and rotated by means of a rack 11 and pinion 12. In the trough are mounted two rollers 19, in such a manner as to be capable (i) of revolving simultaneously with or independently of the shaft 18 upon which they are carried, and (ii) of rising vertically, upon encountering any thick mass of the materials contained in the trough, the curved ends of the rollers coming into contact with the sides of the trough and thus keeping the rollers in position on the shaft. The textile materials which are to be saturated or dyed are placed in the trough, after this has been more or less filled with the necessary liquor, and are conveyed round in the trough and squeezed by the rollers as they are brought under them.—E. B.

Silk; Treating [Weighting] —, F. Jochen, Jersey City, N.Y., Assignor to the Jochen Silk Weighting Co., New York. U.S. Pat. 792,218, June 13, 1905.

THE silk is treated "in the usual manner" with a metallic salt, e.g., "tin bichloride," and is then washed and treated with an alkaline solution of an albuminous substance, e.g., casein, and sodium phosphate, and, finally, again washed and dried.—E. B.

Hydro-Extractor [for Textiles]; Centrifugal —, N. Cantley, Shelf, Yorks. U.S. Pat. 792,755, June 20, 1905.

SEE Eng. Pat. 11,839 of 1904; this J., 1904, 933.—T. F. B.

FRENCH PATENTS.

Silk; Manufacturing Artificial —, P. Cazeneuve. Fr. Pat. 350,723, Jan. 12, 1905.

THE objects of this patent are, first, to describe with greater precision the process of making artificial silk filaments which forms the subject of Fr. Pat. 346,693 (this J., 1905, 194 and 331), and, secondly, to specify certain improvements in the process. Acetone (two or three parts) purified and freed from water, of b.p. 56° C., is employed as sole solvent for the mixture (one part) of tri- and tetra-nitrocellulose, from which the filaments are prepared. The solution is maintained at a temperature of 15°—22° C. during the operation of forcing it through the draw-plates. The opaque threads thus produced are unwound from the spools on which they are received from the draw-plates and are exposed, in the form of hanks, for several minutes to an atmosphere of ammonia, at a temperature of 15°—25° C. This has the effect of rendering them transparent and lustrous. They are next denitrated at a low temperature by means of a solution of ammonium sulphide or hydrosulphide, reagents which

have the property, not shared by metallic sulphides, of increasing the lustre of the filaments, prepared from the solution of nitrocellulose compounds in acetone. Finally, the solvent is recovered by the use of a refrigerating apparatus similar to that employed in condensing carbon bisulphide vapours.—E. B.

Cellulose Threads; Process of Making Lustrous — R. Lunkmeyer and M. Pollak. Fr. Pat. 350,888, Jan. 20, 1905.

SEE Eng. Pat. 1501 of 1905; this J., 1905, 670.—T. F. B.

Dyeing Textile Fibres; Machine for — O. Kunz. Fr. Pat. 350,868, Jan. 19, 1905.

SEE Eng. Pat. 1156 of 1905; preceding these.—T. F. B.

Dye-Vat. D. F. Waters. Fr. Pat. 350,915, Jan. 21, 1905.

SEE U.S. Pat. 785,283 of 1905; this J., 1905, 438.—T. F. B.

Logwood Extracts; Process for Increasing the Tinctorial Yield of — Soc. Lepetit, Dollfus et Gansser. Fr. Pat. 351,018, Jan. 25, 1905.

IN dyeing either animal or vegetable fibres black with logwood extract in the customary manner, the intensity of the shade produced can be increased by 10 to 15 per cent. by the addition of magnesium sulphate to the dye-bath, in the proportion of 15 to 30 per cent. of the weight of logwood extract employed. Magnesium sulphate may also be used with advantage in the manufacture of logwood extracts. In addition to its beneficial effect on the dyeing properties, a so-called "crystallised," dry, granular product is obtained, which is not hygroscopic and contains no tannin matters which injure the shade obtained. The magnesium sulphate may be replaced, though without special advantage, by other magnesium salts.—E. F.

Steaming Apparatus [for Textiles]. R. Sandreuter-Rauch. Fr. Pat. 350,711, Jan. 12, 1905.

A STEAMING-CHAMBER, serving for the treatment of small quantities of textile materials, is divided into several compartments, each of which is independently supplied with steam. A closed steam-pipe is placed near the wall in each compartment to prevent the condensation of the steam and the consequent wetting of the materials during the operation of steaming.—E. B.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

UNITED STATES PATENT.

Coating Materials with Silver; Method of — F. Hilpert, Nuremberg, Germany. U.S. Pat. 792,826, June 20, 1905.

SEE Eng. Pat. 20,703 of 1903; this J., 1903, 1345.—T. F. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Nitric Acid and its Hydrates; Constitution of — W. N. Hartley. Proc. Roy. Dub. Soc., 1905, 10, 373—377.

A SUMMARY of results obtained by the author as the result of spectroscopic observations (Chem. Soc. J., 1903, 83, 658), and a comparison of those obtained by Erdmann (Z. anorg. Chem., 1902, 32, 431) from melting-point and boiling-point determinations, by Veley and Manley (this J., 1901, 1208) from curves of densities and of contractions and from refractive indices, by Pickering (Chem. Soc. Trans., 1893, 63, 436), and by Graham, are given. A list of the hydrates, isolated or indicated by physical data, is as follows:—

Sp. gr.	Composition, Per cent. HNO_3 .	Formula and Constitution
—	100.00	$\text{HNO}_3 = \text{NO}_2\text{OH}$
1.430	89.60	Mixture of $\text{H}_2\text{N}_2\text{O}_7$ and HNC
—	87.65	$(\text{OH})_2 = \text{NO}_2\text{NO}_2$; $(\text{OH})_2 = \text{H}_2\text{O}$
—	77.78	$\text{O} : \text{N}(\text{OH})_2 = \text{H}_2\text{NO}_4$
1.432	72.57	Mixture of $\text{H}_2\text{N}_2\text{O}_7$ and H_2N
1.420	69.80	$(\text{OH})_2\text{N} : \text{O} : \text{N}(\text{OH})_2 = \text{H}_2\text{N}_2\text{O}_6$
1.397	63.63	$(\text{OH})_2\text{N} : \text{H}_2\text{NO}_3$
1.339	53.93	$(\text{OH})_2\text{N} : \text{H}_2\text{O}$
1.263	41.18	$(\text{OH})_2\text{N} : 3\text{H}_2\text{O}$
1.207	33.33	$(\text{OH})_2\text{N} : 5\text{H}_2\text{O}$
1.127	20.31	$(\text{OH})_2\text{N} : 12\text{H}_2\text{O}$

All the experiments indicate unmistakably the basic acid $(\text{HO})_4\text{N} : \text{O} : \text{N}(\text{OH})_4$ (corresponding to ery arsenic acid $(\text{HO})_4\text{As}(\text{OH})_4$) which was the maximum viscosity in Graham's experiments. At the ortho-acid, $\text{N}(\text{OH})_5$, is produced from air whether stronger or weaker, by blowing air through the octobasic acid, exposed to ordinary air saturated moisture, gradually absorbed moisture for five when its sp. gr. was 1.187, and it contained 29.56 of HNO_3 .—J. T. D.

Nitric Acid of High Concentration; Strength and Gravity of — F. Winteler. Chem.-Zeit., 1899, 689.

STIMULATED by the demands of the explosives nitric acid makers have of late years produced high concentration practically free from nitrous acid. The presence of nitrous acid, even in small amount, surprisingly great influence on the specific gravity, acid, and all the older tables of specific gravity erroneous on that account. In consequence of continued analytical discrepancies arising from the nitric acid being determined on the one hand titration, and on the other by observation of the gravity and reference to tables, the author has series of specific gravity determinations and of pure acids of different strengths, the results of which are as follows:—(Lunge's figures are given for comparison. All measurements were made at 15° C.)

Sodium Hydrosulphite; Action of Sodium Polysulphide on — A. Binz. Ber., 1905, 38, 2051—56.

SODIUM hydrosulphite has no action upon sodium polysulphide, but reacts violently with sodium polysulphide, the latter being decolorised, whilst hydrogen is liberated and sulphur precipitated in varying amounts. Definite results are, however, obtained, if sodium polysulphide be added to the mixture. The results of qu-

Zinc Sulphide Ores; Treatment of —. C. E. Dewey.
Fr. Pat. 350,842, Jan. 18, 1905.

Zinc sulphide ores containing iron are roasted until zinc sulphate and zinc oxide, and iron oxide are formed. The product is placed in a V-shaped vat containing water or the washings from a previous charge, and a mixture of air and sulphur dioxide from a sulphur burner; or a mixture of aqueous vapour, air and sulphur dioxide, is injected into the bottom of the vat, so as to agitate the ore in suspension. The zinc oxide is thus transformed into sulphate, and the latter into sulphate by reaction with the ferric oxide present.—E. S.

GERMAN PATENT.

Platinum, Osmium or Palladium in Colloidal Form [Catalytic Substances]; Method of Producing Preparations containing —. Kalle and Co. Ger. Pat. 157,472 Nov. 1, 1903. XX., page 813.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Heat Insulation; particularly with regard to Materials used in Furnace Construction; Notes on —. R. S. Hutton and J. R. Beard. Paper read before the Faraday Society, July 3, 1905. [Advance Proof.]

MEASUREMENTS have been made of the heat conductivity of various granular powders for temperatures up to 100° C.; the method adopted being that of Lees and Chorlton (Phil. Mag. 1896, 41, [5] 495–503).

	Conductivity.
Sand (White Calais)	0.00060
Carborundum	0.00050
Firebrick	0.00028
Lime	0.00029
Magnesia (fused)	0.00047
Magnesia (light calcined)	0.00016
Kieselguhr (infusorial earth)	0.00012

An electrically heated tube furnace enabled comparative tests of the various materials to be carried out at high

temperatures more nearly approaching those experienced in practice. The diagram (see Fig.) illustrates the results obtained. The curves represent the temperature attained and maintained by a given expenditure of power, and illustrate how economies in heating can be effected by a suitable choice of furnace-jacketing material. The authors advise the use of such methods for the comparison of various grades of fire-brick.—R. S. H.

X.—METALLURGY.

Phenomena Accompanying the Reduction of Iron Oxide. R. Schenck and W. Heller. Ber., 1905, 38, 2132—2139.

The reaction $2\text{CO} + \text{C} + \text{CO}_2$ is balanced when $p\text{CO}_2 = \zeta$ (where ζ is the equilibrium-constant); and the reaction $\text{FeO} + \text{CO} \rightleftharpoons \text{Fe} + \text{CO}_2$ is similarly balanced when $p\text{CO}/p\text{CO}_2 = \eta$. If both reactions may proceed at the same time, then when there is equilibrium both of these reactions must hold, and if P be the total pressure of the gases, $p\text{CO} = \zeta/\eta$, and $P = \zeta(1 + \eta)/\eta^2$. As ζ and η are only on the temperature, it follows that the total pressure, as well as the partial pressure of each gas, is only on the temperature; and that, consequently, the reduction of iron oxide in presence of carbon will be reduced by the presence of monoxide if the total pressure of the carbon monoxide and monoxide present be less than P , while, if the total pressure be greater than P , iron will be oxidised by carbon separated. The authors have directly determined P for different temperatures, starting both from iron and carbon with carbon dioxide, and from a mixture of carbon and ferrous oxide, keeping the pressure of the apparatus constant till the pressure began to change. The results were as follows:—

Starting from Metallic Iron.		Starting from Ferrous Oxide.	
Temp. ° C.	P. mm.	Temp. ° C.	P. mm.
900	10.9	468	10.3
—	—	540	30.0
—	65.0	—	—
—	—	620	81.5
—	—	660	169.2
300	308.0	—	—
350	395.8	728	438.4
—	—	778	750.0
—	—	780	780.0

The results of the two methods agree very closely. It is seen that, working under normal conditions (i.e., atmospheric pressure), there can be no reduction, if an indifferent gas be present, below about 775° C., for at that temperature is the equilibrium-pressure P of the total pressure of the reacting gases; and to work at a lower temperature it is necessary to reduce that pressure, either by working in a partial vacuum or by adding an indifferent gas. In the blast-furnace, where air is used to produce carbon monoxide, the total pressure of the carbon oxides cannot exceed 0.1 atm., and hence reduction may occur at all temperatures above about 695° C. If, locally, the temperature fall below that, the conditions exist for the reoxidation of the reduced iron and the deposition of carbon. Manganese being much more readily oxidised than iron, the value of ζ is in its case much higher, and hence that much lower, than in the case of iron. The authors were unable to get any measurable value of P for manganese below 1200° C. (10 mm.). At 1220° it was 7 mm., but the experiments could not be continued on account of the damage to the quartz tube at these high temperatures.—J. T. D.

Relation to one another of the Different Modifications of Carbon. R. Schenck and W. Heller. Ber., 1905, 38, 2139—2143.

The reaction on one another of carbon, carbon monoxide, carbon dioxide, the equilibrium-constant ζ depends on a given temperature) on the particular modification of carbon concerned; and if the corresponding constant for iron, ferrous oxide, carbon monoxide and carbon dioxide be η , then the condition for equilibrium among these five of these substances at any temperature is that

$$P = \zeta \frac{1 + \eta}{\eta^2}$$

where P is the total pressure of the two reacting gases.

It follows (since η does not involve carbon) that P must be proportional to ζ ; and the authors have determined P for various temperatures, using amorphous carbon (sugar carbon), diamond powder, purified graphite, and carbon reduced by iron from carbon monoxide. The results, plotted in curves, show that the value of P with temperature is roughly similar in all cases, becoming more rapid as the temperature rises; but that at any given temperature the value of P is highest for amorphous carbon, lower for diamond, and lowest for graphite, the gap between diamond and graphite being very much greater than that between amorphous carbon and diamond. The results for carbon monoxide-carbon all fit exactly on the graphite curve, showing that this reduced carbon is very finely divided graphite. Graphite is thus the most stable form of carbon, and reductions (that of iron, for instance) can only be carried out with graphite instead of amorphous carbon (or with coke, say, instead of wood-charcoal) if the temperature be suitably raised.—J. T. D.

Steels; Tin-, Titanium-, and Cobalt-. — L. Guillet. Comptes rend., 1905, 140, 1689—1691.

The author has examined steels of varying carbon content, containing up to 10 per cent. of tin, up to 9 per cent. of titanium, up to 60 per cent. of cobalt. Each of these metals dissolves in the iron, and the carbon present exists entirely as iron carbide. None of the three metals (tin, titanium and cobalt) influences sensibly the mechanical properties of the steel, so that no industrial application of the respective alloys suggests itself. The difference between tin or titanium and silicon, or even between cobalt and nickel, in this respect, is very remarkable, the cobalt steels, like those of tin and titanium, failing entirely to manifest the properties so much valued in nickel steel.—J. T. D.

Copper and Zinc; Alloys of. — O. Sackur. Ber., 1905, 38, 2186—2196.

The author has investigated the behaviour of alloys, containing different proportions of these two metals:—1. By observing the limiting composition of those which will precipitate copper from solutions of sparingly soluble salts or salts with complex ions (euprous thiocyanate, iodide, bromide, chloride, double cyanide and ammonio-eupric compounds), and the rate of precipitation in the cases in which it occurs; 2. By observing the rates of attack of the alloys by acids, especially N/20 sulphuric acid; 3. By determination of the melting and solidifying points, and examination of the curves obtained. The results all agree in indicating changes in the constitution of the alloys with about 41—45 per cent. and 60—62 per cent. of copper. The author considers that the main constituents other than the metals themselves are the compounds CuZn_2 (32.7 per cent. of copper) and CuZn (49.3 per cent. of copper); that the alloys of lower copper content are mixtures of the first compound with zinc, but that, owing to dissociation of CuZn_2 , there is still free zinc present when the composition of the alloy reaches that of the compound, and that the change in character at 41—45 per cent. of copper is due to the disappearance of free zinc through the influence of the excess of copper on the dissociation of the compound; and that alloys richer in copper are mixtures of the two compounds with metallic copper, the compound CuZn_2 only ceasing to be present when the excess of copper has neutralised the tendency of CuZn to dissociate, i.e., at 60—62 per cent. of copper. Changes in the colour of the alloys, at 40 per cent. of copper, from grey to reddish-yellow, and at 60 per cent. from the latter colour to golden-yellow, also indicate discontinuity at these two points.—J. T. D.

ENGLISH PATENTS.

Steel; Melt or Bath for Hardening. — S. N. Brayshaw. Manchester. Eng. Pat. 12,816, June 7, 1904.

The bath is prepared by mixing 10 parts of sodium chloride with seven parts of potassium chloride. This mixture fuses at a temperature of about 700° C. If desired, a

carburising agent, such as potassium ferrocyanide, may be added to the extent of about 1 oz. per cwt. of the mixture.—W. P. S.

Metals or Metallic Articles: Deposition of Metals (Antimony) or Metallic Compounds upon — S. Cowper-Coles and Co., Ltd., and S. Cowper-Coles, London. Eng. Pat. 13,579, June 15, 1904.

The metallic article to be coated, cleansed from scale or oxide, is immersed in finely-powdered antimony, which may contain up to 25 per cent. of oxide, and from 1 to 6 per cent. of carbon may, in some cases, be added. The antimony powder is contained in a closed vessel, which is heated, but not sufficiently to fuse the powder, and which is meanwhile rotated or otherwise agitated, to ensure intimate contact between the article and the antimony powder. It is desirable to prevent, as far as possible, access of air to the contents of the vessel during the process. The coating of antimony produced is crystalline, and may be equal to an oz. to the sq. ft. of surface for, say, an hour's treatment.—E. S.

Metal: Method of and Apparatus for Removing Superfluous Metallic Coating from Sheet — R. E. Phillips, London, from O. S. Fellows and A. E. Hopkins, Middletown, N.Y., U.S.A. Eng. Pats. 5377 and 5379, March 14, 1905.

THE excess of metal is re-melted *in situ* by means of an elongated gas-burner or other suitable contrivance, and then removed by a blast of air, steam, or hot water.

—J. H. C.

Metal: Method of and Apparatus for Removing Superfluous Metallic Coating from Sheet — R. E. Phillips, London, from O. S. Fellows and A. E. Hopkins, Middletown, N.Y., U.S.A. Eng. Pats. 5378 and 5380, March 14, 1905.

THE excess of metal is re-melted and then removed by brushing.—J. H. C.

Aluminium: Special Solder or Flux whereby Ordinary Solder can be used to Solder — A. W. King, and The Advertising Mirrors Co., Ltd., London. Eng. Pat. 3589, Feb. 21, 1905.

THE "special solder or flux" obtained by melting together at a low red heat, 10 parts of soft solder, 5 parts of pure zinc, and from 5 to 8 parts of aluminium, all by weight, and cast in bars or the like, is used to rub on the heated aluminium surfaces to be joined, which, thus prepared, may be soldered by ordinary soft solder.—E. S.

Boiler Feed Water: Utilising a certain Waste Product (Galvanising Liquors) for the Treatment of — W. Branley. Eng. Pat. 17,690, Aug. 15, 1904. XVIII B., page 811.

UNITED STATES PATENT.

Steel: Method of Making Open-hearth — N. McConnell, Pittsburg, Pa. U.S. Pat. 792,914, June 20, 1905.

MOLTEN pig metal is blown in an acid-lined converter, in which the silicon and part of the carbon are removed. Portions of the molten metal are then transferred from time to time, to an intermediate furnace, heated externally, in which a large "pool" is maintained, and from which charges are taken to basic open-hearth furnaces, in which the metal is dephosphorised and decarburised.—E. S.

FRENCH PATENTS.

Steel and Iron: Process and Apparatus for Making Castings of — G. Marconnet. Fr. Pat. 359,359, Jan. 13, 1905.

THE iron ore is charged from above into a cupola provided with valved conduits or tuyères composed of refractory material, at or near the bottom. Through these, passing a separate heating chamber, powdered mineral and carbon are driven by means of a fan, where the mineral is reduced to molten iron or steel as metal is required.—J. H. C.

Steel: New Process for Making — in the Martin-Silbermann Furnace, operating in two or more Stages and Employing a Decantation Pocket. H. J. B. Delnorte. Fr. Pat. 350,750, Jan. 14, 1905.

THE fused metal is run from the furnace into a "pouring" ladle, where, after partial cooling, the slag is removed and the metal thus partially refined is run back to the furnace for further treatment.—J. H. C.

Metals: Concentrating Volatile — by the Dry Way of Mixed Sulphides. H. Pape. Fr. Pat. 351,042, Jan. 14, 1905.

THE sulphide ores are finely powdered, and the powder is injected with a current of air into a roasting chamber maintained at a high temperature, if necessary by aid of an auxiliary furnace. The volatile sulphides, as those of lead and zinc, with the lighter oxides, are swept forward by the gases of combustion into a communicating condensing chamber, whilst the heavier oxides, such as those of copper and iron, together with the gangue are deposited in the roasting chamber.—J. H. C.

Fluids of Different Densities (Slag and Matte): Method of Keeping — Separate and of Distributing them in Distinct Currents. H. Harris. Fr. Pat. 351,443, Jan. 13, 1905.

THE fluids, e.g., slag and matte, from a blast-furnace are introduced into an oblong trough or receiver, which is divided by a transverse partition having an opening at the lower end of the bottom of the trough through which the denser fluid passes to the further compartment. Each compartment is furnished with a spout through which the liquid is finally led away.—J. H. C.

Slag: Manufacture of Objects (Building and Decorating Materials) from Blast-furnace — A. F. Le Châtelier. Fr. Pat. 350,659, Jan. 10, 1905. IX., page 802.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

(A).—ELECTRO-CHEMISTRY.

Nitrogen: Oxidation of Atmospheric — in the High-Tension Electric Flame. A. Stavenhagen. Ber., 1905, 38, 2171—2177.

IN the experiments described, an electric flame discharge was produced in a porcelain tube, through which a current of air was passed. The tube was surrounded by a large condenser containing absolute alcohol cooled with liquid air. The nitrous fumes were absorbed in standardised sodium hydroxide solution, but the absorption was not quite complete. An accurate determination of the current-yield was not possible owing to the difficulty of ascertaining the strength and pressure of the secondary current, but the following data are given:—The electric discharge was produced by means of an inductor capable of giving a spark 33 cm. long, this coil being connected to a Wehnelt interruptor and a source of electric current of 15—18 amperes at 100—110 volts. The current from losses the secondary current had a calculated strength of 0.07 ampère at 20,000 volts. The following are some of the results obtained: in a few experiments, a small quantity of oxygen was added to the air.

mic.	Velocity of Air Current.	Velocity of Oxygen.	Volume of N/10 NaOH Solution neutralised in 10 mins.	Strength of Electric Current.

...mo-electric Couples; Improved Manufacture of Copper Sulphide for —. Comp. Thermo Electrique

(Système Hermite). Soc. Anon., Paris. Eng. Pat. 11,300, May 30, 1905; Under Int. Conv., April 27, 1905.

Copper sulphide, which after its formation is allowed to cool in presence of excess of sulphur, so as to become saturated therewith, is melted in a crucible, and metallic copper is added in small portions until reaction ceases, and the copper sulphide thus obtained is freed from the copper, which latter serves for another operation. Or cupric oxide may be added to melted copper sulphide, whereby sulphur dioxide is disengaged and copper is deposited, leaving the special copper sulphide, which is stated to be perfectly stable, and to give quite regular thermometric results.—E. S.

UNITED STATES PATENT.

Electrolytic Cell. J. F. Kelly, Pittsfield, Mass., Assignor to Southwestern Exploration Co., New Mexico. U.S. Pat. 792,597, June 20, 1905.

This invention relates to an electrolytic cell divided into three compartments, the central electrolyte compartment containing the substance to be decomposed, such as an alkali sulphate, and being separated from the anode and cathode compartments by osmotic diaphragms which prevent "mass mingling" of the liquids. The anode and cathode are of substances not attacked by the acid and alkali respectively, which are the products of the electrolytic action.—B. N.

FRENCH PATENT.

Accumulators; Process of Manufacture of —. F. E. Polzeniusz and R. Goldschmidt. Fr. Pat. 350,898, Jan. 20, 1905.

This invention relates to a process of making accumulator plates of zinc-nickel, iron-nickel, &c., the active mass being deposited by electrolytic means as a thin firmly adherent porous layer on a suitable conductor. These are placed in a solution which has no chemical action on the active masses, the positive and negative plates being insulated from each other by means of cloth or parchment.—B. N.

(B.)—ELECTRO-METALLURGY.

Copper; Some Notes on the Rapid Electro-Deposition of —. S. Cowper-Coles. Paper read before the Faraday Society, July 3, 1905. [Advance Proof.]

THE author reviews the different methods for increasing the rate of deposition in electrolytic copper refining, and describes recent developments of his method of revolving the cathode at a critical speed. The critical speed above which smooth, tough deposits can be obtained was determined for any current density by the use of a conical cathode. The variation of bath voltage and current density for rotating cathodes at the critical speed, is illustrated by a curve. Variation of the speed of rotation causes lamination. The plant required for the centrifugal process and the cost of working are also dealt with.

—R S. H.

ENGLISH PATENT.

Furnace; Electric — L. L. Bosworth, Cleveland, Ohio. Eng. Pat. 2313, Feb. 6, 1905.

THE furnace consists of an outer shell or casing surrounding a refractory non-conducting solid body, around which are wound, from end to end, two resistance coils insulated from each other and from the casing. At one end of the refractory body is an oven into which is fitted a muffle, the latter being made in two sections, one sleeved upon the other, and triangular in cross-section, with walls converging towards the closed end of the muffle in the interior of the furnace. Around the inner section is wound an electrical heating coil, the inner terminal of the coil passing through the outer section, and being brought to the front of the muffle. The resistance and heating coils are in series, and connected with the main terminals by conductors passing through the furnace from front to back. The inner section and heating coil may be withdrawn together, in the event of repairs to the wire being necessary. —B. N.

UNITED STATES PATENT.

Metal Mixtures Produced as a By-product in Electrolytic Metal Refining; Process of Treating — A. G. Betts, Troy. U.S. Pat. 793,039, June 20, 1905.

SEE Eng. Pat. 15,298 of 1904; this J., 1905, 626.—T. F. B.

FRENCH PATENT.

Furnace; Oscillating Electric —, with Conducting Solid. Soc. Anon. Electrometallurgique (Procédés Paul Girod). Fr. Pat. 350,802, Jan. 16, 1905.

THIS invention relates to an electric furnace with a conducting sole acting as one of the electrodes, the other pole consisting of a free electrode of graphite. The furnace is suspended on two trunnions carried by fixed supports or by a waggon, so that the furnace may be oscillated by mechanical means or by the hand. The material is thus poured from the furnace and this gives a regular composition and yield. Two openings are provided for tapping the material, the lower one being used when the sole becomes worn through continued use.—B. N.

Metals; Electrolytic Process of Obtaining on —, Deposits with a Metallic Lustre. A. Classen. Fr. Pat. 350,964, Jan. 23, 1905.

A METALLIC lustre is obtained on metals deposited electrolytically by the addition to the electrolytic bath of a certain quantity of one or a mixture of the following substances:—glucosides, phloroglucosides, phloroglucides, gummides, mannides, glucosides containing nitrogen, or the derivatives of any of them. Instead of these, the extracts of plants, barks or roots containing these substances or their derivatives may be used.—B. N.

XII.—FATTY OILS, FATS, WAXES, AND SOAP.

Vegetable Oils; Flashing-Points of Some — M. Rakusin. Chem.-Zeit. 1905, 29, 690—691.

THE following determinations of flashing-points were made by Herr Kryloff, Chief of the Laboratory of the Imperial Russian gun-factory at Tula:—

Oil.	Sp. gr.	Flashing-point.
		°C.
Cocoanut	0.924	200
Linseed	0.930—0.935	205—225
Rape	0.915	215
Mustard	0.914	225
Gallipoli	0.914—0.919	235—240
Olive	0.916	240
Sesame	0.923—0.924	240
Poppy	0.924—0.935	250
Hemp	0.925—0.930	250—265
Castor	0.968	255—270

Any mineral oil adulterant is readily detected by lowering of the flashing-point which it causes. This is particularly the case with castor oil, where the adulterant must be colourless.—J. T. D.

Glycerol; Determination of — by the Extraction Method with special Reference to its Separation from the Glycerol Waters obtained in Enzymic Processes. W. Landsberger. Chem. Rev. Fett- u. Harz- Ind., 1905, 12, 150—1.

PARALLEL determinations of glycerol were made by the acetin method as prescribed by Le-wkowitsch and by the extraction method of Shukoff and Schestakoff (this J., 1905, 294). The results given in detail were as a rule in close agreement, but in certain cases the values given by the extraction method were somewhat too high. The partially concentrated glycerol water of sp. gr. 1.05 yielded 38.2 per cent. of glycerol by the acetin method as against 40.3 per cent. by the extraction method, suggested that it is not impossible that in such cases certain substances other than glycerol may have been extracted by the acetone, even in the presence of sodium sulphate. A drawback of the method is the time required for a determination—at least nine hours under favourable conditions.—C. A. M.

Ether; Oxidising Action of Impure —, and its Influence on Kreis's Reaction. H. Ditz. XXIII., page 8

ENGLISH PATENTS.

Separator and Filter for Mixed Liquids [e.g., Oil and Water]; An Improved — H. G. Small and the Frictionless Engine Packing Co., Ltd. Eng. Pat. 17,625, Aug. 13, 1904. L., page 791.

Waste [Cotton, Polishing Cloths, &c.]; Cleaning Oil — O. Wilhelm. Eng. Pat. 18,720, Aug. 30, 1904. L., page 798.

Linseed Oil; Apparatus for Heating — with Dr. J. Buchanan. Eng. Pat. 7646, April 11, 1905. XI 3., page 807.

Photograph Records; Composition for use in Making of —, and Process of making the Same. G. C. M. London. From The New Jersey Patent Co., Orange, New Jersey, U.S.A. Eng. Pat. 3070, Feb. 3, 1905.

THE composition claimed consists of a mixture of a metallic soap or soaps with a hard wax, such as carnauba wax (preferably combined with stearic acid to form a compound ester), and non-hygroscopic substances, such as ceresin, and colouring materials such as lampblack. Special claim is made for a composition on these lines prepared by melting 45.5 kilos. of commercial stearic acid at 115° C., and adding an aqueous solution of 50 kilos. of carbonate and sodium aluminate, and subsequently 71 kilos. of carnauba wax. The mixture is then heated to 232° C., so that the excess of stearic acid may combine with the alcohols in the wax, and is then incorporated with 9.71 kilos. of ceresin, from 0.9 to 3 per cent. of lampblack, and finally with sufficient stearic acid to give the desired solidification point, preferably 145° C., and the whole strained through muslin before use. The composition is stated to flow readily when melted, to take a good impression from the matrix, and to give a smooth polished record, which is free from air bubbles, and will keep well in damp or hot climates.—C. A. M.

Soap and Detergent Compounds; Manufacture of — H. J. Armstrong and M. R. Armstrong, Ashton-under-Lyne, Ribblesdale, and H. H. Armstrong, Penwortham, Preston. Eng. Pat. 17,218, Aug. 6, 1904.

COMPOUNDS of ammonia, preferably ammonium sulphate, and of boron, such as borax, are coated either separately or together with a layer of protective material, such as wax, paraffin wax, &c., and incorporated with the salts, with the result that the reaction between the salts does

ace until required. A detergent powder is obtained by using such soap with hydrated sodium carbonate, and claim is made for the addition of calcium borate, for dishwashing and cleaning soap for metals, glass, &c., and for polishing material such as pumice, &c., &c. Specified proportions of the protected salts are 10 per cent. for soft soap and about 5 per cent. for hard soap.—C. A. M.

Process of Manufacturing ——. J. F. G. de la Haye de Sales, Paris. Eng. Pat. 1292, Jan. 23, 1905. Inter. Int. Conv., March 24, 1904.

Acid (Oleic); Process for Converting — into Fatty Acid and Similar Compounds. A. de Hemptinne. Fr. Pat. 350,955, Jan. 23, 1905.

Eng. Pat. 1572 of 1905; this J., 1905, 448.—T. F. B.

GERMAN PATENT.

Process of Preparing Stable Iodine or Bromine Compounds ——. E. Merck. Ger. Pat. 159,748, Sept. 9, 1902. Addition to Ger. Pat. 96,495, April 8, 1897.

Iodine or bromine substitution products of fats can be obtained by the action of bromine or iodine on a fat in presence of water and of some reducing agent (e.g., sulphur dioxide); by this means it is stated that the greatest possible amount of halogen can be introduced into the fat. The original patent described the use of iodochloride or bromochloride for this preparation.—T. F. B.

Balm of Honduras; The so-called ——. A. Tschirch. Schweiz. Wochenschr. Pharm., 1905, 43, 238. Chem. Abstr., 1905, 1, 1705.

The new balsam has nothing in common with the peculiar Peru balsam, from the fruit of *Myroxylon Peryvianum*, which belongs rather to the class of storax balsams. It is free from cinnamic acid, a solid resin-ester of cinnamic acid with a colourless, solid resin-alcohol of the same character as storacinal, and a mixture of liquid resins of cinnamic acid. The Honduras balsam thus only resembles storax, and the odours of the two substances are also alike. It is doubtful whether the Honduras balsam is identical with the white Peru balsam described by Thoms and Biltz (this J., 1904, 1111), but the latter cannot be regarded as a genuine white Peru balsam, which would contain coumarin, but no cinnamic acid, either free or combined.—A. S.

Use of Carbon Tetrachloride; Use of ——. as a Solvent in the Manufacture of Varnish. L. E. Andés. Chem. Rev., 1905, 12, 157.—158.

EXPERIMENTS to determine the solubility of the raw materials used in the manufacture of varnish in carbon tetrachloride gave the following results:—*Insoluble* (but dissolving on the addition of a relatively small amount of alcohol or turpentine oil): Yellow, acaroid resin, gum zoin, soft (so-called "spirit-soluble") and hard Manila resin, gum mastic, sandarac, shellac, celluloid, and agate

shellac. *Partially Soluble or Swellable*: Calcium carbonate, fused lead and manganese resins, the former dissolving completely on the addition of turpentine oil, whilst the latter does not. Finely-powdered Manila copal also swells up in the solvent. *Soluble*, Syrian asphaltum (and probably other varieties of asphaltum), Brazil copal, small fragments swell up without dissolving. Panama resin (a turbid solution becoming clear on the addition of 50 per cent. alcohol), galipot, colophony, larch turpentine, fused Zanzibar copal and amber gumlac.

Shellac is soluble in a mixture of 70 parts by weight of carbon tetrachloride and 30 parts of 25 per cent. alcohol, whilst sandarac and mastic dissolve in mixtures of 80 to 90 per cent. of carbon tetrachloride with 20 to 10 per cent. of spirit. It is thus possible to prepare two distinct types of varnishes according to the proportion of carbon tetrachloride used, viz., ordinary brush varnishes, which are thin, transparent, and flow easily, and varnishes for dipping or pouring, which, owing to the volatility of the carbon tetrachloride, cannot be applied by means of a brush, but give a very brilliant coating when applied in other ways. Varnishes containing fatty drying oils can also be prepared by means of carbon tetrachloride, and the addition of as little as 10 per cent. of this to the solvent makes the varnish transparent and to flow well from the brush. If larger proportions are used the product can only be employed as a "dipping" varnish. A brilliant black enamel varnish for small iron articles can be prepared from asphaltum by means of carbon tetrachloride, whilst copals give colourless varnishes.—C. A. M.

ENGLISH PATENT.

Linseed Oil; Apparatus for Heating ——. with Driers. J. Buchanan, Aberdeen. Eng. Pat. 7646, April 11, 1905.

CLAIM is made for an apparatus in which the mixture of oil and driers is maintained at a uniform temperature, the oil being either in the raw state or after preliminary decolorisation and heating in a vessel partially immersed in a hot bath of an aqueous solution of, e.g., caustic alkali. This bath may have an arrangement of pipes with apertures in the sides connected with a condenser, so as to serve the purpose both of conveying the evaporated steam to the condenser and of returning the condensed liquid to the bath. The influence of the air upon the caustic alkali may be obviated by connecting the steam pipe beyond the condenser with a closed vessel containing air, so that the latter can be used over and over again.—C. A. M.

UNITED STATES PATENT.

Turpentine or other Products from Wood; Apparatus for Recovering ——. R. A. Sibbitt, Carleton Place, and A. K. McLean, Ottawa. U.S. Pat. 792,934, June 20, 1905.

THE apparatus consists of a retort with a conical bottom, supported in a casing; the space between the retort and casing communicates with the furnace, which is situated on one side of the retort. A discharge pipe is provided in the centre of the bottom of the retort, and passes through a cooling apparatus, supported immediately beneath the retort.—T. F. B.

(C).—INDIA-RUBBER, Etc.

Naphthalene; India-Rubber as an Absorbent of ——. J. O. V. Irminger. H., page 793.

ENGLISH PATENT.

Indianrubber; Process for Reclaiming Waste Vulcanised ——. H. F. Gregory, London, and T. M. Thom, Cheshunt, Herts. Eng. Pat., 8378, April 19, 1905.

THE vulcanised rubber is washed, finely powdered, and freed from mineral matter by boiling with hot dilute hydrochloric acid, and from excess of sulphur by boiling with dilute caustic soda solution, the residue being washed

after each treatment. The dried rubber is then treated with a solvent consisting of about 25 lb. of aniline and 10 galls. of "naphtha" to each 100 lb. of the substance, and the mixture, after standing for a few hours, is heated by means of steam to 250°–280° F. until solution is complete. The mass is then strained and can be used for moulding, &c., the solvent evaporating during the process, but is unsuitable for revulcanisation. C. A. M.

XVI.—SUGAR, STARCH, GUM, Etc.

Beet Juice: Influence of the Nitrogen on the Purity of —. K. Andrlík and J. Urban. Z. Zuckerind. Böhmen, 1905, 29, 519–522.

THE authors have studied the relations between the percentage of the injurious melassigenic nitrogen (see following abstract) and the total non-sugar constituents of the concentrated saturation juices. An average of a large number of determinations showed that one part of injurious melassigenic nitrogen corresponds to 16.1 parts of total non-sugar. The ratio (16.1) of the injurious melassigenic nitrogen to the total non-sugar is a fairly constant value, and it is termed the "nitrogen co-efficient." If K_n = the nitrogen co-efficient and N_s = the proportion of injurious melassigenic nitrogen per 100 parts of sugar, the quotient of purity of a thick juice can be calculated by the expression:

$$Q = \frac{10000}{100 + K_n \times N_s}$$

The calculated results agree satisfactorily with actual determinations. Assuming that 97 per cent. of the sugar and 90 per cent. of the melassigenic nitrogen are extracted from the raw beets, the above expression can be employed for estimating the relative value of beetroots, and for judging the degree of purity which may be expected in the concentrated saturation juice.—J. F. B.

Beetroots and Sugar Factory Products: Determination of the Objectionable [Melassigenic] Nitrogenous Matter in —. K. Andrlík. Z. Zuckerind. Böhmen, 1905, 29, 513–518.

THE melassigenic nitrogenous matter of beet products is defined as that which remains dissolved after the precipitation of the albuminoids and the removal of the ammoniacal and amide nitrogen. The solution of cupric hydroxide employed for precipitating the albumin is prepared by decomposing 200 grms. of copper sulphate by caustic soda and dissolving the precipitate in 2 litres of water containing 20 c.c. of glycerol.

One hundred grms. of beet pulp are placed in a marked to contain 403 c.c., and are diluted with to about 340 c.c., the pulp is digested on the water at 80°–85° C. for 15 minutes, 40 c.c. of the cupric re are added together with 10 c.c. of a solution containing 200 grms. of crystallised aluminium sulphate per The whole is shaken and diluted to 403 c.c., and dig again at 80°–85° C. for 15–30 minutes; after co the total volume is again adjusted to 403 c.c., an liquid is filtered through a dry filter. The total ni is determined in 100 c.c. of the filtrate by Kjel method, and the nitrogen in the form of ammoni amides is determined in a second 100 c.c. by boiling two hours with 1 c.c. of concentrated sulphuric aci distilling from magnesia. The difference between two determinations is expressed as melassigenic ni A sample of thoroughly exhausted beet molasses con 1.92 per cent. of melassigenic nitrogen and pol 48.0 per cent. On the assumption that 90 per ce the melassigenic nitrogen of the beet is extracte percentage of total molasses produced can be calcu from the expression

$$M = \frac{\text{percentage of melassigenic nitrogen in beet} \times 0}{\text{polarisation of molasses.}}$$

The relations most usually found in practice are:—0 per cent. of melassigenic nitrogen in the beet, yielding 3 per cent. of total molasses, i.e., 1.75 per cent. in the sugar, and 2.0 per cent. as actual molasses.—J. F. B.

Sugar Crystals: Process and Apparatus for Producing — from Solutions. V. Schütze, Riga, 1905. Eng. Pat. 3972, Feb. 25, 1905.

THE apparatus consists of a long horizontal jacketed cylinder, connected with a vacuum pump, with inlet and outlet passages through hollow trunnions. The jacketed space is divided by a helical partition which causes the cooling liquid to take a spiral course from one end to the other. The sugar syrup, at a concentration of about 50 per cent. and a temperature of 70° C. is admitted to the interior of the vessel, water at 70° C. having been previously introduced into the jacket space. The vessel is then rotated slowly, and cold water is admitted to the jacket at the discharge end of the cylinder. Under the influence of the vacuum, the syrup is concentrated during its passage through the vessel and is gradually cooled at the same time. In this manner, large and pure crystals are built up and are collected in a receiver at the discharge end.—J. F. B.

Starch-like or Amyloid-like Substances and Starch: Process for Manufacture of —. A. Börner, Vienna. Eng. Pat. 16,262, July 22, 1904.

CELLULOSE and materials containing cellulose, such as sawdust, shavings, peat, grass, &c., are treated with a warm, dilute solution of mineral acid, organic acid, caustic alkali or borax, until a sufficient quantity of a starch-like body has been removed. The latter is then separated from the residue and freed from resin, if necessary, and the starch-like substance is precipitated by cotton salt.—J. F. B.

II.—BREWING, WINES, SPIRITS, Etc.

The Steeping of Malting — J. L. Baker and D. Dick, *J. Inst. Brewing*, 1905, 11, 372–384.

The authors have studied the rate of absorption of water by barley in the steep and have recorded the results in the form of curves. In all these curves certain irregularities or breaks were observed, corresponding in some cases to a temporary cessation of the absorption of moisture for short periods, and in others to an actual decrease in moisture already absorbed. Kiln-dried barley absorbed water in larger quantity and at a greater rate than green barley. Experiments were also conducted to determine the retarding influence of low temperatures upon the rate of absorption of water by barley. The rate of absorption of water in the steep was found to be absolutely independent of the activity of zymes of the barley. The authors also studied the effects of the germinative properties of the barley upon the rate of absorption of water by the steep, and by aeration during steeping. The retardation of the growth caused by steeping at low temperatures was very marked after 72 hours' germination, but was practically compensated for after 120 hours' growth. Experiments on the effect of the time of steeping upon the rate of absorption of water by barley illustrated the retarding influence both of under-steeping and of over-steeping on the vigour of the growth. The authors confirm the statements of Windisch and others of the stimulating influence of aeration during steeping, and of the retarding influence of aeration during steeping and improving the vigour of the growth and development of the roots. The barley, steeped with water, was found to possess a distinctly lower diastatic power than the barley steeped in the ordinary manner. —J. F. B.

Autodigestion of — J. Effront, *Monit. Scient.* 1905, 19, 485–491.

The autodigestion of yeast may be divided into two processes: (a) the digestion of the carbohydrates, starch, cellulose, &c., and the fermentation or oxidation of the products; (b) the digestion of the albuminoids. In the first process yeast undergoes autodigestion in presence of water, both these processes take place concurrently. In the absence of water the auto-digestion of the yeast is accompanied by a progressive loss of fermentative power, and the cells are all dead after 10 days at 30° C. When the autodigestion takes place in presence of water and alcohol, the digestion of the carbohydrates is very feeble, and the action is almost entirely confined to the digestion of nitrogenous matters. In this case the cells remain apparently intact, with slight structural alterations. The yeast retains its vitality, the effect of its autodigestion at 30° C. in aqueous alcohol being only to delay the commencement of fermentation for 3 hours, in spite of the loss of 90 per cent. of the nitrogenous matters. The following table shows the percentage of the original constituents remaining in the yeast after digestion:—

Yeast re- duced of its original.	A After 10 days in water.	B After 10 days in aqueous alcohol.	C After 30 months in aqueous alcohol.
Substance	Per cent.	Per cent.	Per cent.
Starch	12.8	31.8	29.7
Albuminoids	14.6	10.8	7.59
Hydrates	11.2	64.3	64.4
.....	6.25	10.0	22.2

In all cases traces of formaldehyde and amyl alcohol were observed amongst the products of digestion.—J. F. B.

Yeast Mash (Distillation); Lactic Acid — W. Henneberg, *Z. Spiritusind.* 1905, 28, 203–204.

In studying the acidification of the distillate by yeast mash, by B. Delbrück on the large scale, the author found that provided the necessary high temperature be maintained, the acidification after the sowing of the yeast pure culture will maintain itself technically pure for a very long time, i.e., for months. Infection is automatically suppressed as soon as it occurs. In spite of the comparatively low temperature which exists at the surface of the mash, only the true culture bacillus, *B. Delbrücki* exists there. At a temperature of 50° C. (on the large scale) the quantity of acid produced is only about one-half, and at 56° C. only one-third of that produced at 40° C. The most favourable temperature for the acidification is 46–47° C. In the laboratory, on the other hand, the acidification is frequently not impaired at 50° C. For the detection of gross infections, such as would be objectionable in practice, a droplet culture prepared direct from the acid mash is sufficient; but for very slight infections the infecting organism must be concentrated by sub-cultivation at 27° C. in sterilised mash.—J. F. B.

Fermentation of Glucose [Dextrose] by Yeast Juice; Influence of Phosphates on the — A. Harden and W. J. Young, *Chem. Soc. Proc.*, 1905, 21, 189–191.

It has been previously pointed out that the amount of dextrose fermented by a given volume of yeast juice is greatly increased by the addition of boiled and filtered yeast juice (see this J., 1905, 246). The increased fermentation is the result of two phenomena: (a) The addition of the boiled yeast juice causes an initial rapid evolution of carbon dioxide, which soon diminishes until a rate is attained which remains practically constant for many hours. (b) This steady rate is, in general, about the same as that observed with an equal volume of the same yeast juice and sugar, without any addition of boiled juice, but diminishes more slowly than this, so that the fermentation continues for a longer period. The greater proportion of the total increase is usually due to this second phenomenon. An addition of a solution of sodium or potassium orthophosphate also causes an initial rapid evolution of carbon dioxide, but not any marked prolongation of the fermentation. It was found that the extra quantity of carbon dioxide evolved during this initial period is a function of the amount of phosphate present, one molecular proportion of the gas being evolved for every atom of phosphorus added in the form of alkali orthophosphate, or present in the boiled yeast juice in a form precipitable by magnesia mixture. The greatest amount of carbon dioxide obtained in this way from 25 c.c. of yeast juice was 0.46 gram, corresponding with the addition of about 1.5 grams. of anhydrous disodium-hydrogen phosphate. The initial rapid evolution of carbon dioxide represents the fermentation of a corresponding amount of dextrose, as, in all cases, an equimolecular proportion of alcohol was produced. If the liquid in which fermentation has been carried on in presence of phosphate, be boiled and filtered, the added phosphorus is contained in the filtrate, but is no longer in a form precipitable by magnesia mixture or silver nitrate.—A. S.

Cider; Production of Sweet — G. Warcollier, *Comptes rend.*, 1905, 140, 1711–1713.

The anaërobic activity of yeast is limited and the secretion of zymase gradually ceases in absence of air, leaving more or less of the sugar unfermented. The degree of attenuation should, therefore, be capable of being regulated at will by limiting the quantity of yeast sown, and controlling its multiplication by excluding the air to a suitable extent. The author has applied the above principles with a view to producing a sweet cider, only partially fermented, which will keep in absence of air without ulterior multiplication of the yeast and without tendency to "fret." For this purpose the apple must should contain a minimum quantity of dissolved oxygen, and should be fermented with a limited quantity of yeast, being maintained with rigorous exclusion of air during fermentation and racking. Experiments in the laboratory with sterilised musts, sown with mere traces of yeast and

fermented in closed flasks, have verified the correctness of this view and have shown that attenuation can be curtailed to an extent far beyond that necessary for an ordinary sweet cider. When similar fermentations were carried out at a temperature of 35° C. they ceased after 8 days; at this temperature, however, the cider did not retain the carbon dioxide and required artificial saturation. Unsterilised must, prepared on the practical scale, was converted into sweet cider by drawing off into bottles, with exclusion of air, yielding a clear cider with a gravity of 1.025 clear and free from all but traces of yeast. This cider, when bottled with exclusion of air in such a manner that the bottles were filled right up to the corks, remained perfectly stable, and had a good sparkle; the condition and flavour were exceptionally uniform.—J. F. R.

Sulphur in By-products of Molasses Distillery: Variations of Proportion of —. K. Andrlík and V. Stanek. Z. Zuckerind. Böhmen, 1905, 29, 522–525.

THE authors have determined the proportion of total sulphur in the by-products of a molasses distillery at various stages:—

Total sulphur calculated as SO_2

	in 100 parts of ash.	on 100 parts of K_2O in the ash
Original molasses	2.31	4.1
Thin vinasse	7.24	13.3
Concentrated vinasse from the the Porion evaporator ...	11.18	21.3
Calcined vinasse	8.63	18.0

The proportion of sulphur in the molasses, increases up to the stage preceding calcination, and then decreases. The increase of sulphur in the thin vinasse, as compared with the original molasses, is due to the addition of sulphuric acid before fermentation, this addition being equivalent to 5.42 parts of sulphuric anhydride per 100 parts of the ash of the molasses. The increase of sulphur during the process of evaporation is due to the sulphur in the fuel (lignite) employed in the Porion evaporator. The decrease during calcination represents loss of sulphur by volatilisation in the form of sulphuretted hydrogen, carbon bisulphide, &c.—J. F. R.

Cereals; Determination of Available Extract in Flaked —. L. Briant, XXIII., page 817.

ENGLISH PATENTS.

Starch-like or Amyloid-like Substances and Sugar; Process for the Manufacture of —. A. Börner. Eng. Pat. 16,262, July 22, 1904. XVI., page 808.

Drink free from Alcohol; Production from Fermented Fluid of a —. H. Linzel and C. Bischoff, Berlin. Eng. Pat. 17,651, Aug. 13, 1904.

THE alcohol is removed from a fermented liquid, such as beer, by heating the latter under reduced pressure, and at the same time passing a current of steam and air into the beer at such a rate that the partial condensation of the steam keeps the volume of the liquid constant. It is claimed that the alcohol is quickly removed by this process, whilst the heavier volatile constituents of the hops and beer remain in the liquid.—W. P. S.

Evaporator for Evaporating the Liquid in Brewer's Wash, Sewage, Waste or Spent Dyes and the like, and Concentrating the Solids in the same, the Evaporator being also applicable as a Smoke Washer. A. B. Lennox. Eng. Pat. 13,227, June 11, 1904. XVIII., page 811.

FRENCH PATENT.

Yeast; Manufacture of "Vinnese" —. Soc. des Prod. Amylacés. Fr. Pat. 350,793, Jan. 16, 1905.

THE cellular residues from the manufacture of starch from

grain, containing all the nitrogenous matters, are mixed with a sufficient quantity of starchy material, and the mixture is digested with water under a steam pressure of three atmospheres for about 30 minutes. The mass obtained is cooled to 68° C., and is saccharified by the addition of malt. The wort is then employed for the manufacture of yeast and alcohol.—J. F. R.

GERMAN PATENT.

Brewers' Yeast; Process for Making Dead —, maintained, for the Purpose of Utilising it as Nutrient Material for the Cultivation of Distillery Yeast —. Kues. Ger. Pat. 158,655, Nov. 1, 1903.

THE waste brewers' yeast, after pressing, is intimately mixed with 20–30 per cent. of an acid phosphate (preferably superphosphate), and the mixture is dried at 40–45° C., sterilised and powdered.—A. S.

Cream Separators; Impts. in —. J. Meys, Frankfurt. Eng. Pat. 16,070, July 20, 1904.

THE drum of the separator is provided with a series of internal plates a^1, a^2, a^3, a^4, a^7 , each of which is made of a number of cone-shaped parts having different inclinations, b, c , to the axis. The milk is introduced through the pipe R, and passes from this through the opening o , under the plate a^1 , from where it flows through the openings f, f^1 , into the

under the plate a^2 , then under a^3, a^4 , &c. The milk is detained for a time at the steep parts $e-b$, whilst the cream is pressed over the more horizontal parts, and rises until it flows out at g , the skimmed milk being forced up through the pipe L. If desired, the cream may be provided with grooves or channels, u , through which the cream can pass, and the slots, f , may be dispensed with.—W. P. S.

and like Liquids; Apparatus for Treating —, to use the Globules of Cream or Fat to a State of Fine Division. C. W. Schou, Copenhagen. Eng. Pat. 8, Feb. 13, 1905.

milk is forced under high pressure through a slit 1 by a cylindro-conical core fitting into a hole of ponding cross section. The core is hollow and is in position by a spindle and spring. The hole in which the core passes is bored cylindrically for its length, and for the remainder slightly conically. The core or shoulder on the core also serves to keep it in position. The core may be in the shape of a tube which encircles another fixed core, or it may consist of sections of different cross section areas passing through corresponding holes.—W. P. S.

d Beverages; Compositions for Making —. J. Jones, London. Eng. Pat. 6617, March 29, 1905.

parts of alkali compounds of albuminous substances, such as those described in Eng. Pat. 15,719, 1898, 1899, 390, milk powders, or powdered milk are mixed with an aerating agent, such as tartaric acid sodium hydrogen carbonate. The mixture may be mixed with sugar, gelatin, or the like, and pressed into tablets or packed in gelatin capsules. Heat may be applied to the tablets.—W. P. S.

ENGLISH PATENTS.

ator for Evaporating the Liquid in Brewers' Wash, Sege, Waste or Spent Dyes and the like, and Concentrating the Solids in the same, the Evaporator being also applicable as a Smoke Washer. A. B. Lennox, New-son-Tyne. Eng. Pat. 13,227, June 11, 1904.

ion to be evaporated is placed in the upper part of a tank, where it falls, in the form of a spray, through a perforated plate, to the bottom of the tank. As it falls,

it meets a current of hot air which is blown through the tank. Baffle plates are provided to cause the air current to take a circuitous course through the tank. The air inlet and outlet are placed just above the surface of the layer of liquid which collects at the bottom of the tank. This layer is drawn off as it accumulates by means of a pump and returned to the upper part of the evaporator. The concentrated liquor is finally drawn off through suitable taps. (See also this J., 1905, 342.)—W. P. S.

Sewage; Treatment of —. T. Henderson, Oxford. Eng. Pat. 13,588, June 15, 1904.

SEWAGE that has passed through a preliminary process of aerobic decomposition, is led successively through a series of deep tanks, where bubbles of air are blown through it. The spraying device for the air consists of a funnel-shaped vessel. The air enters at the stem and leaves through a number of small holes in a plate fixed across the top of the funnel. Immediately below this plate is a second plate, and below this, again, is a third. These two latter plates have larger holes corresponding with the groups of small holes in the upper plate, and the middle plate is movable, so that the air supply can be cut off when desired.

—W. P. S.

Sewage; Process of Treating and Utilising — [as Fuel]. A. McLean, London, and W. Paterson, Dumfries. Eng. Pat. 1,776, Jan. 30, 1905.

THE liquid portion of the sewage, after precipitation, is passed through filtering layers, such as those described in Eng. Pat. 22,724, 1904 (this J., 1905, 655). The solid portion or sludge is mixed with about 10 per cent. of quick-lime in a mill. The mixture is then conveyed to a series of filtering trays, where the bulk of the water is drawn off by means of a reduced pressure formed in a space below the trays. When practically dry, the mass is removed from the trays, and carried to a revolving, drying chamber heated by a furnace. It is then mixed in a steam-jacketed vessel with about 10 per cent. of tar, and, if necessary, a little more quick-lime, and pressed while still hot into blocks for use as fuel. The liquid extracted from the sludge by the filtering trays is further filtered before being discharged from the outfall.—W. P. S.

Boiler Feed Water; Utilising a Certain Waste Product [Galvanising Liquors] for the Treatment of —. W. Bramley, Middlesbrough. Eng. Pat. 17,690, Aug. 15, 1904.

THE water is treated with a dismercurant formed by neutralising the waste hydrochloric acid solution of iron chloride from galvanising works, with barium carbonate or barium sulphide. When the latter is used, the solution may be heated to expel the hydrogen sulphide. In cases where the water requires less barium chloride than that which would be yielded by neutralising with the barium salt alone, a part of the latter may be replaced by zinc or iron oxide. The quantity of iron added to the water should be equivalent to the bicarbonates present, and the amount of barium added should be about half that equivalent to the calcium sulphate in the water.—W. P. S.

Water; Method and Means for Softening —. Mather and Platt, Ltd., and G. G. Hepburn, Manchester. Eng. Pat. 17,920, Aug. 18, 1904.

THE water is treated with lime and alkali, and then passed over rough metallic surfaces such as borings or turnings. The latter may be contained in layers in a vessel which has a bottom-plate perforated with jagged openings. A preliminary settling of the precipitate may be allowed to take place before passing the water through the above metallic beds.—W. P. S.

Water or other Liquids; Method and Apparatus for Effecting the Destruction of Pathogenic Organisms in —. P. G. Griffith, Green Lanes, Middlesex. Eng. Pat. 17,984, Aug. 18, 1904.

THE water is led from a tank through a closed chamber by means of a number of zigzag pipes. From the latter it is led into a second chamber, where it is heated to a

temperature of 65°–85° C. by means of a steam pipe. The duration of the heating does not exceed 25 seconds. The hot water then passes back into the first chamber, by a pipe leading from the top of the heating chamber, so that it is cooled by the water passing through the zig-zag pipes. The treated water is finally drawn off at the bottom of the first chamber.—W. P. S.

Tartrates; Solubility of some Metallic — in Water.
H. H. Cantoni and F. Zachoder. Bull. Soc. Chim. 1905, 33, 747–754.

THE authors have continued their work on the solubility of metallic tartrates in water (see this J., 1904, 190). The results obtained are shown in the following table and in the curve-diagram (see Fig.).

Temperature.	Strontium Tartrate $C_4O_6H_4Sr \cdot 3H_2O$.	Calcium Tartrate $C_4O_6H_4Ca \cdot 4H_2O$.	Barium Tartrate $C_4O_6H_4Ba$.	Temperature.	Copper Tartrate $C_4O_6H_4Cu \cdot 3H_2O$.	Zinc Tartrate $C_4O_6H_4Zn \cdot 2H_2O$.	Lead Tartrate $C_4O_6H_4Pb$.

Mercury; Formates of —. R. Varet. Comptes rend., 1905, 140, 1641–1643.

YELLOW mercuric oxide dissolves readily in dilute formic acid, giving mercuric formate, which, however, slowly changes into mercurous formate, with liberation of formic acid and carbon dioxide. The mercurous salt is easily obtained in crystals. The author has determined the molecular heats of formation of these two salts in solution, from liquid mercury, diamond, and gaseous hydrogen and oxygen, as 173.1 and 161.5 calories for the mercurous and mercuric salts respectively. The mercurous salt is thus the more stable of the two.—J. T. D.

Curve No. 1—Strontium tartrate.
Curve No. 2—Calcium tartrate.
Curve No. 3—Barium tartrate.
Curve No. 4—Copper tartrate.
Curve No. 5—Zinc tartrate.
Curve No. 6—Lead tartrate.

The form of the solubility curves for copper and zinc tartrates is probably due to the hydrated salt losing some of its water of crystallisation on heating, with formation of a salt containing less or no water of crystallisation, the solubility of which decreases with rise of temperature.—S.

Dimethyl Sulphate; Formation of Esters with —. Graebe. Annalen, 1905, 340, 244–249.

ALMOST theoretical yields of esters are obtained by the solid potassium salt of the acid with a moderate excess of dimethyl sulphate to about 120° C. in an oil bath. On raising the temperature to 200°–210° C., the ester comes off. Potassium benzoate and acetate in this way gave theoretical yields of the respective esters. Chlorophthalic acid gave a yield of about 60 per cent.; the yield is the same if the acid is dissolved in three molecules of sodium hydroxide in a 10 per cent. solution, and then warmed with three molecules of dimethyl sulphate. Naphthalic acid, treated by either method, gives about half the above yield. Anhydrous phosphorus chloranilate heated for nine hours in a closed vessel in a water-bath with dimethyl sulphate gives a good yield of the ester.—F. S.

modifications described, are represented in Figs. 1 and 2. In Fig. 1, E is a vessel containing mercury, and on raising this the mercury enters the adjoining tube driving gas out at the vessel A. Any excess of mercury which comes to A overflows by the pipe B to C, and so to E. D is a valve which closes C when E is raised, to avoid breakage due to a too rapid ascent of the mercury. A glass at V_1 and V_2 is contracted. Another type of pump is shown in Fig. 2. A and B are three-way stopcocks, and a piece of rubber tubing with screw-pinch, and open to the air, is attached to A (as shown). C is an ordinary stopcock. The bulb to be evacuated is attached to D, and E is connected with a pump (Bunsen water-pump), which gives a vacuum of 1 cm. or better. F is a vessel containing a drying gas, G, H and J are valves. K is a glass vessel into which a measured amount of mercury is introduced. Mercury is poured into L through E until the inner tube dips below the surface.

Fig. 2.

use the pump, the stopcock at A is turned so as to connect towards E, the screw-pinch-cock at A being closed. The pump attached to E is then started. When the necessary vacuum in K is obtained, A is turned so as to connect towards E, and the pinch-cock on the rubber tube at A is gradually opened so as to admit air. The mercury then rises into the bulb and tubes above K, and at H and J. A is then again opened towards E, and evacuation once more begun. The mercury flows into K from above, and so on. The limb at M contains some mercury which acts as a seal. The advantages of the pump are:—(1) The small size of manipulation; (2) the rapidity of working; (3) the mercury keeps clean. The pump is operated by using mechanical contrivances at A the pump is automatic.—C. E. F.

ENGLISH PATENT.

Gas Mixtures; Process of and Means for Testing Composition of — F. Haber, Karlsruhe, Germany. Eng. Pat. 18,047, Aug. 20, 1904. The process claimed for testing gaseous mixtures consists

in causing light to pass non-normally through the common surface of contact of the mixture to be tested and a medium of comparison, and determining the deflection. The mixture and the comparative gas may be separated by a plate, through which the light passes non-normally. The comparative gas can be one constituent of the mixture isolated by absorption of the other constituent. A simple device for carrying out this test is described and figured.—F. S.

INORGANIC—QUALITATIVE.

Nitrites, Nitrates and Chlorates; Detection of — by Diphenylamine with Resorcinol or β -Naphthol. P. Alvarez. Bull. Soc. Chim., 1905, 33, 717–719.

THE author finds that a mixture of diphenylamine with resorcinol or β -naphthol gives more certain results than diphenylamine alone, especially as a test for nitrates and chlorates. The reagent is prepared by dissolving 0.1 gm. each of pure diphenylamine and resublimed resorcinol in 10 c.c. of sulphuric acid (sp. gr. 1.84); five or six drops of this solution are added to 0.001 gm. of the salt in a flat-bottomed porcelain capsule. The following colour changes are obtained:—

Nitrates.—Greenish yellow. A thin film on the capsule becomes blue at the edges, especially on blowing. Addition of alcohol gives an orange liquid.

Nitrites.—Intense purple blue. A thin film becomes red at the edges. Addition of alcohol gives a red liquid.

Chlorates.—(β -naphthol in place of resorcinol) Dark green changing to grey and finally black. Addition of alcohol yields a greyish or blackish liquid.—F. Spx.

INORGANIC—QUANTITATIVE.

Silica and Fluorine; Separation and Determination of — F. Seemann. Z. anal. Chem., 1905, 44, 343–387.

THE author has critically examined the various methods for the separation and determination of silica and fluorine, and particularly those which may be applied to minerals, &c., containing both these substances. He finds that silica is most completely separated by precipitation with mercury-ammonium carbonate. The latter is prepared by treating mercuric chloride solution with an excess of ammonium carbonate until the precipitate which forms is re-dissolved, or by digesting freshly precipitated mercuric oxide in an excess of ammonium carbonate solution. The silica solution should be neutralised with hydrochloric acid before adding the reagent, and the mixture twice evaporated to dryness. The residue obtained is easily filtered and washed, and may be directly ignited, when anhydrous silica is obtained. After precipitating the silica with mercury-ammonium carbonate and filtering, the filtrate may be used for the determination of the fluorine. For this purpose the methods proposed by Fresenius, Brandl, Oettel, Carnot and Offermann all give trustworthy results. Precipitation of the fluorine as calcium fluoride is not to be recommended.—W. P. S.

Antimony; Electrolytic Determination of — H. D. Law and F. M. Perkin. Paper read before the Faraday Soc., July 3, 1905. [Advance Proof.]

THE authors propose the use of tartrate solutions in view of the trouble of preparing the sodium sulphide solutions hitherto employed for the electrolytic determination of antimony. A solution of an antimony salt containing 6 to 8 grms. of ammonium tartrate in 120 c.c. of solution is recommended. The deposition is complete in from three to five hours. Current density 0.2 to 1.0 ampère per sq. dm. with P.D. of 2.6 to 3.5 volts. The deposition is preferably carried out from a warm slightly acidified solution.—R. S. H.

Tellurium; Determination of — by Electrolysis. G. Pellini. Gaz. chim. ital., 1905, 35, 514–516.

An adherent electrolytic deposit of tellurium can be obtained by using a rotating cathode consisting of a cylindrical beaker of platinum with a matt surface. A known

weight of carefully purified tellurium was dissolved in the platinum beaker in nitric acid of sp. gr. 1.25, which was then removed by evaporation, 10 c.c. of strong sulphuric acid being afterwards added and the liquid heated for some time on a sand-bath. On cooling, from 30 to 40 c.c. of a cold saturated solution of ammonium hydrogen tartrate was added to the liquid, which was then shaken and boiled until all the tellurous acid was dissolved, after which a further quantity of the tartrate solution was added so as to bring the total volume of the liquid to 250 c.c. The solution was then electrolysed at 60° C. with a current density of 0.12—0.09 ampère per 100 sq. cm. and a potential difference of 1.8—2.2 volts, the deposit of tellurium being kept immersed by the addition of water previously boiled and cooled in a stream of carbon dioxide. At the end of the electrolysis, which occupied from 7 to 124 hours, the current was stopped, and the still rotating cathode washed with purified water, and then with absolute alcohol. The cathode was then dried for 10 minutes at 90—95° C. and weighed. The results obtained have errors varying from 0.08 to 0.16 per cent. It is found that quantities of tellurium greater than 1 gm. can be deposited, so that the method may be used for the purification of this element.—T. H. P.

Superphosphate : (Determination of) Free Acid in —.
L. Schuchet. Z. angew. Chem., 1905, 18, 1020—1023.

Of solvents other than water for extraction of the free acid the author finds acetone most satisfactory. It possesses the following advantages over alcohol or ether:—(1) It dissolves the free acid quickly at the ordinary temperature. (2) It does not liberate phosphoric acid from ferric or aluminium acid phosphates. (3) Titration may be performed without first removing the solvent. Five grms. of the superphosphate are spread as a thin uniform layer on a Büchner's filter of 9 cm. diameter, and is washed ten times with neutral acetone (about 75 c.c.), which runs very rapidly through the filter. The filtrate becomes turbid but clears again on addition of 200 c.c. of water. The free acid is then titrated in the same manner whether acetone or water has been used. Instructions are given for avoiding two sources of error—(a) Acid phosphates of iron and aluminium are precipitated by caustic soda before methyl orange changes from red to yellow, but may be kept in solution by potassium oxalate; (b) Phosphoric acid, which acts as a monobasic acid in this titration, is neutralised so slowly that it is necessary to hasten the reaction by sodium chloride. A sample analysis is given:—To 500 c.c. of a superphosphate solution (20 grms. per litre) were added 29 c.c. of N 1 neutral potassium oxalate, slightly less than that required to precipitate the calcium. After boiling and filtering, 40 c.c. of 4N/1 sodium chloride were added to 200 c.c. of the cooled filtrate (= 3.78 grms. of substance), which was then titrated with N 2 caustic soda and methyl orange.

The author condemns drying the sample in any case, as changes are brought about by heating. Small quantities of sulphuric and other acids liberate phosphoric acid on storing, and may therefore be reckoned as such. Acid phosphates are not hydrolysed by water alone except in great dilution.—F. SBN.

Ammonia in Drinking Waters : Determination of —.
Cavalier and Artus. Bull. Soc. Chim., 1905, 33, 745—747.

The authors have examined the method proposed by Trillat and Turchet (this J., 1905, 251) for the determination of ammonia, based upon the formation of a black precipitate of nitrogen iodide on addition of potassium iodide and alkali hypochlorite. They find that the method is much less delicate than that of Nessler, as the black coloration is not produced with quantities of ammonia less than 3 mgrms. per litre, whereas 0.1 mgrm. of ammonia per litre can be recognised by the Nessler test. A more serious disadvantage of the method, however, is the fact that the black coloration fades sensibly in the course of one minute and disappears almost completely in two or three minutes.—A. S.

ORGANIC—QUALITATIVE.

Cocoanut Oil : Method of Determining the Purity of —.
E. Milliau. Comptes rend., 1905, 140, 1702.

THE test is based upon the fact that seed oils give a go-berry-red coloration when treated with both phloroglucinol and resorcinol in an acid medium, the reaction being less sensitive when only one of the reagents is employed. Four c.c. of the cocoanut oil are shaken in a test-tube with 2 c.c. of a saturated solution in ether of phloroglucinol and then with 2 c.c. of a saturated solution of resorcinol in benzene, and the tube immersed for a few seconds in water at 10° C. The mixture is then treated with 4 c.c. of nitric acid (40°) free from nitrous vapours, transferred to another test-tube, and shaken for a few minutes, the tube being meanwhile closed by a stopper of rubber previously washed in the same acid. Perfectly pure cocoanut oil remains practically unchanged, and a rose colour speedily disappearing points to the presence of negligible traces of impurities. But in the presence of 5 per cent. or less of any grain oil, or of lard oil, naphthas or resin oils, the pronounced red coloration is obtained. Any colorations subsequently produced by the prolonged action of the nitric acid are to be ignored.—C. A.

Ether : Oxidising Action of Impure — and its Influence on Kreis's Reaction. H. Ditz. Chem.-Zeit., 1905, 29, 705—710.

COMPOUNDS such as ethyl peroxide and hydrogen peroxide are formed in ether on exposure to the air, and the presence of such peroxidised ether may produce unexpected phenomena, such as the formation of periodides of caffeine alkyl iodide, as shown by Rossolimo (this J., 1904, 288), or the decolorisation of an alkaline solution of cobaltous oxide (this J., 1901, 389), which may be employed as a test for peroxides in ether. The author's experiments with various modifications of Kreis's reaction (this J., 1904, 1001) for decomposed or insolated impure ether was used, and that when obtained without ether it could be destroyed by the addition of the peroxidised product. The latter could be purified by stirring over sodium hydroxide for two days, and then dried to interfere with the reaction. The ethyl peroxide in the ether was found to have a much more energetic action than the hydrogen peroxide—a result in agreement with Rossolimo's experience. Rancid fats gave a brown coloration instead of the red when impure ether was used in the test, which was evidently due to some other reaction. On shaking a solution of phloroglucinol in ether with concentrated hydrochloric acid, a reddish-brown coloration was obtained, and the reaction was so sensitive that it could be used as a test for traces of peroxides in the ether. The intensity of the reaction increased with the proportion of phloroglucinol, a 0.1 per cent. solution giving a bright yellow coloration. Sesame oil that had been kept fresh for a year gave an intense coloration in Kreis's reaction (bluish-green colour with concentrated hydrochloric acid, this J., 1899, 1158; 1904, 194), but the coloration disappeared on the addition of the impure ether. When the sesame oil was treated, first with the ether and then with the concentrated acid, only a greenish-yellow coloration of the acid, changing to yellow, was obtained. The author attributed this to the action of the ethyl peroxide, a phenolic substance, sesamol, isolated by Kreis, and caution is given as regards Wiedmann's modification of Kreis's test (5 c.c. of a 0.1 per cent. solution of phloroglucinol in acetone with 5 c.c. of the melted fat or three drops of concentrated sulphuric acid), for the coloration was obtained in certain cases where the reaction gave a negative result. This was found to be due to aldehyde in the ether, and the same coloration was produced in a blank experiment in which the fat was absent. Kreis attributed his reaction to the presence of at least two hydroxyl groups in a meta position in the molecule and to the presence of aldehydes or ketones in the impure fat (this J., 1903, 575), and in this connection the author calls attention to various reactions with formaldehyde. An aqueous solution of resorcinol treated with formaldehyde

acidified, and heated gave a red-brown insoluble
precipitate, whilst *o*-*m*- or *p*-cresols gave only white or faint
precipitates under the same conditions. It was
found that the colour reactions were not invariably
governed by two hydroxyl groups in the meta position.
Under certain conditions, red or reddish-violet
precipitates were given by, e.g., salicylic acid and catechol
formaldehyde.—C. A. M.

Pyruvic Acid; Colour Reaction for the Detection of —.
by α - or β -Naphthol and Sulphuric Acid. P. Alvarez.
Bull. Soc. Chim., 1905, 33, 716—717.

Freshly prepared solution of α - or β -naphthol
(0.1 gm. to 0.05 gm.) in sulphuric acid of sp. gr. 1.83
has already been proposed by the author as a
reagent for the investigation of the organic acids (Comptes
Rendus, Feb. 8, 1897). One drop of the acid is added to
a solution of the reagent in a porcelain capsule, which is
gently warmed. The following colour changes are
observed with pyruvic acid:—

Naphthol.—The reagent acquires a bright red colour
on cooling, changing to an intense blue on warming.
Addition of water or alcohol causes a fugitive yellow
precipitate to develop.

Naphthol.—The reagent becomes yellow in the cold,
changing to an intense orange on very gentle warming.
The colour persists after dilution with water or alcohol.
The test serves to distinguish between this and other
acids such as citric, tartaric, malic, &c., and also obviously
between α - and β -naphthols.—F. SDN.

Phenols; New Reagent for the Detection of —. P.
Alvarez. Bull. Soc. Chim., 1905, 33, 713—716.

The reagent is hydrated sodium dioxide ($\text{Na}_2\text{O}_2 \cdot 8\text{H}_2\text{O}$).
It is employed in the following manner. To 0.20 gm.
of anhydrous dry sodium dioxide, 0.04 gm. of
residual phenol and 5 c.c. of absolute alcohol
added in a small porcelain dish of 30 c.c. capacity.
On the reaction the dish is gently rotated, four to six
minutes being allowed (A). Finally 15 c.c. of cold distilled
water are added (B). The colorations obtained are given
below:—

	A	B
Phenol	Rose-colour, changing to green, finally brown. Film on dish, greenish- blue by blowing.	Reddish-brown.
Catechol	Pale yellow, changing to greenish.	Green, more intense.
Resorcinol (hydro- quinone)	Very intense reddish- yellow. Film on dish, transient blue by blow- ing.	Orange.
Pyrocatchol	Brownish-red	Intense red. Orange in 24 hours.
Hydroquinol	Purple red, changing to brown.	Film on dish, yellow.
Glucosinol	Purple blue	Colour more intense, but almost colour- less after 24 hours.
Resorcinol	Intense rose colour ...	Rose colour.
Catechol (hydro- quinone)	Purple blue, changing at once to red. Film on dish, greenish-yellow in air.	Reddish-brown, edges yellow.
Quinacridone	Intense orange. Film on dish, intense yellow.	Wine-red, fading slowly.

—F. SDN.

ORGANIC—QUANTITATIVE.

*Leather; Method for the Detection and Deter-
mination of —, in Tan-yard Liquors.* J. G. Parker
and V. Casaburi. Collegium, 1905, 210—212.
The early stages of tanning while the pelt is in an unfixed

condition, considerable waste of hide substance occurs,
by reason of the action of bacteria and various salts
present in the liquors, which act on the hide substance,
rendering it soluble in acid or alkaline liquors; this
"peptonised" hide substance differs from ordinary hide
substance in producing a compound with tannin capable
of being dissolved in excess of gallic and other acids.

The authors propose the following method for accurately
determining the amount of soluble leather or hide substance
present in a tan-liquor, and state that by its use neither
the nitrogen from the ammonium salts introduced into
the liquor by the hides, nor that naturally present in the
liquor is determined.

200 c.c. of the unfiltered tan-liquor are treated with
25 c.c. of a concentrated sodium acetate solution, and ferri-
acetate solution is afterwards slowly added until precipi-
tation no longer takes place. The precipitate after filtra-
tion is washed, allowed to drain, and the nitrogen present
estimated by Kjeldahl's method.—M. C. L.

*Beetroots and Sugar Factory Products; Determination
of the Objectionable (Melassigenic) Nitrogenous Matter
in —.* K. Andrlik. XVI., page 808.

Sucrose; Polarimetric Determination of —. F. Watts
and H. A. Tempamy. West Indian Bull., 1905, 6,
52—60.

The authors have made careful observations with pure
sucrose, with a view to determining the correction
which should be applied to compensate for the decrease
in the rotatory power of sucrose at tropical tempera-
tures. Determinations made at 30° C. have led the
authors to propose the correction:— $\text{Pol.} + (0.00023t)N$, for
this error, where N = the Ventzke scale degrees, and t =
the difference between the temperature of observation
and that at which the instrument was graduated. Com-
bining this correction with that proposed by Jobin for
the change of rotatory power of the quartz wedge, the
total correction of the polarimetric reading for tropical
temperatures (about 30° C.) becomes: $\text{Pol.} + (0.00039t)N$.

The authors have also determined the error due to the
volume of the lead precipitate and found that the volume
of this precipitate varies according to the quality of the
sugar, being 0.305 to 0.45 c.c. for Muscovado sugars.

At tropical temperatures the error due to the volume
of the lead precipitate practically compensates that due
to the change in the rotatory powers of the sucrose
and quartz, but at the normal temperature the error due
to the lead is very serious.

They find that Horne's method (this J., 1904, 340) of
adding dry lead subacetate to the sugar solution is very
nearly accurate, provided the lead be not used in excess.

The following rules are proposed for the polarisation of
sugars:—

- (1) Dissolve 26 grms. of the sample and dilute to
100 true c.c. (equivalent to 26.048 grms. in 100 Mohr c.c.).
- (2) Clarify by means of "anhydrous" basic lead acetate,
avoiding excess (0.35 gm. gives good results with Mus-
covado sugars).
- (3) Polarise at the same temperature as that at which
the solution has been prepared and correct the reading
by the formula $\text{Pol.} + (0.00038t)N$.—J. F. B.

Cereals; Determination of Available Extract in Flaked —.
L. Briant. J. Inst. Brewing, 1905, 11, 395—398.

In order to avoid the variations in the results found when
malts of different diastatic powers are mashed together
with the flaked cereals (see Baker; this J., 1905, 353),
the author prefers to effect the conversion of the starch
by means of a cold-water extract of malt, instead of by
the malt-grist itself. Experiments have shown that,
provided sufficient of the malt extract be employed, the
results are perfectly concordant with malts of widely
divergent diastatic powers.

A tender, good malt, preferably one with a diastatic
power between 30° and 40° Lintner, is ground and ex-
tracted for 1½ hours with three times its weight of cold
water. Twenty grms. of "flakes" are mixed in a beaker
with 120 c.c. of water, and the temperature is raised to
160° F. with constant stirring; 50 c.c. of the filtered

cold-water extract of malt are added gradually, and the mash is allowed to remain at a temperature of 150° F. for two hours. The mash is then cooled to 60° F., diluted to 200 c.c., and filtered. The difference between the sp. gr. of the filtered wort and that of the malt extract after treatment in exactly the same manner, when multiplied by the factor 3.32, gives the lb. of available extract contained in 336 lb. of "flakes."—J. F. B.

Hydrazides: Determination of some —. C. Maselli, *Gaz. chim. ital.*, 1905, 35, 267—273. *Chem. Centr.*, 1905, 1, 1742.

THE method is based upon the fact that semicarbazide and semioxamizide when boiled with dilute acid in aqueous solution are decomposed, in accordance with the following equations:—

Determination of Semicarbazide.—The aqueous solution of the semicarbazide salt is rendered acid with sulphuric acid, boiled for $\frac{1}{2}$ hour, an excess of a standardised solution of potassium iodate added, and after again boiling, the excess of iodate titrated with sodium thiosulphate.

Determination of Semioxamizide.—In this case, owing to the formation of oxalic acid, the amount of hydrazine produced cannot be determined by means of potassium iodate. The solution after boiling with sulphuric acid, is therefore rendered alkaline with sodium hydroxide, and the ammonia distilled off and determined.—A. S.

XXIV.—SCIENTIFIC & TECHNICAL NOTES.

Synthesis by means of the Silent Electric Discharge. J. N. Collie. *Chem. Soc. Proc.*, 1905, 21, 201—202.

By subjecting pure ethylene to the action of the silent electric discharge in a vessel cooled to -20° C., a liquid was produced together with some hydrogen gas. In one experiment about 40 c.c. of hydrogen were obtained from 210 c.c. of ethylene. On fractionating the liquid reaction-product, the distillate collected mainly in two portions distilling between 100° and 150° C. and 150° and 200° C. respectively. The residue, amounting to 40 per cent. of the total, was a dark resinous substance, which on heating gave an odour resembling that of burnt india-rubber. Small quantities of aldehydes were formed when a mixture of ethylene and carbon monoxide was subjected to the action of the silent electric discharge, but the chief reaction that took place was the same as in the preceding experiments, the ethylene condensing to form hydrocarbons having high boiling points. The substances chiefly formed, boil at about 150°—160° C., and appear to approximate in composition to $\text{C}_{10}\text{H}_{20}$; on further condensation, loss of hydrogen occurs and compounds approximating both in properties and composition to terpene derivatives are produced.—A. S.

Acids: Influence of various Sodium Salts on the Solubility of Sparingly soluble —. J. C. Philip. *Chem. Soc. Proc.*, 1905, 21, 200.

EXPERIMENTS with cinnamic, benzoic, salicylic and *o*-nitrobenzoic acids and sodium formate, acetate and butyrate, showed that the solubility of the acids was increased by addition of sodium salts of weak acids. If this increased solubility be due to the formation of undissociated sodium salts of the sparingly-soluble acids, then the extent to which the solubility of the acid is increased by the presence of the sodium salt NaA would depend on the strength of the acid HA. This was found to be the case, curves obtained by plotting the concentration of the added salt (NaA, NaA', NaA'', &c.) against the concentration of the sparingly-soluble acid in the saturated solution of the salt, being in the same order as the strengths of the acids HA, HA', HA'', &c.

It is pointed out that these results are in agreement with the view that the greater solubility of magnesium hydroxide in ammonium chloride solutions than in pure

water, is due to the formation of undissociated ammonium hydroxide, and the consequent removal of hydroxyl ions leading to the solution of more hydroxide.—A. S.

Diazo Reactions: Influence of Light on —. K. J. Orton, J. E. Coates and F. Burdett. *Chem. Proc.*, 1905, 21, 168—169.

PREVIOUS experiments on the action of light on diazo reactions have, apparently, been carried out exclusively with the solid substances (this J., 1890, 1001; 1901, 1001). The authors have studied the effect of light on solutions of diazonium salts. On boiling an aqueous or acid solution of a *s*-tribromobenzenediazonium salt, no *s*-tribromophenol is formed (*J. pr. Chem.*, 1883, 27, 113; *Ber.*, 1883, 23, 2517), but dibromoquinonediazide is chiefly produced, with liberation of bromine (*Chem. Soc. Trans.*, 1902, 83, 802). When, however, solutions, especially acid solutions, of the diazonium salts are exposed to sunlight, the diazo compound is rapidly decomposed even at the ordinary temperature, with formation of *s*-tribromophenol and nitrogen. The corresponding bromobenzenediazotates are not affected in the slightest degree by exposure to sunlight. The decomposition of *s*-tribromobenzenediazonium salts in methyl alcohol, alcohol and acetic acid solutions is also affected by light. On boiling the solutions, *s*-tribromobenzenediazide is formed in all three cases, but by exposure to sunlight the products are *s*-tribromoanisole, $\text{C}_6\text{H}_2\text{Br}_3\text{OCH}_3$, *s*-tribromophenol, $\text{C}_6\text{H}_2\text{Br}_3\text{OC}_2\text{H}_5$, and *s*-tribromophenyl acetate, $\text{C}_6\text{H}_2\text{Br}_3\text{O.C}_2\text{H}_3\text{O}$, respectively. Similar results were obtained with other diazonium salts and diazotates. Solutions of diazonium salts can be kept at the ordinary temperature for some weeks in the dark, but decompose rapidly on exposure to sunlight, with formation of the corresponding phenol. The results of the experiments indicate that the conversion of diazo compounds into phenols, ethers and phenylacetates is a reaction characteristic of the diazonium ion.—A. S.

Soot: Some Constituents of Manchester and other —. E. Knecht. *Mem. and Proc. Manchester Lit. and Phil. Soc.*, 1905, 49 [14].

THE soot taken for examination was an average sample obtained from bulk at a dealer's. It was extracted with boiling dilute sulphuric acid to remove basic constituents, then with sodium hydroxide to separate acid compounds and phenols, and finally with benzene to extract hydrocarbons. In all samples under examination it was found that the aqueous extract showed a strongly acid reaction, due to the presence of free sulphuric acid. It also contained practically the whole of the ammonia and pyridine bases. From the acid extract, impure calcium sulphate was separated, whilst the filtrate from the latter was found to contain ammonia equivalent to 10.7 per cent. of ammonium sulphate calculated on the weight of original soot. From the alkaline extract, left after previous boiling the soot with dilute sulphuric acid and washed with water, a dark brown liquid was obtained, which, on acidification, yielded a brown product having a strong sooty odour, resembling humic acid in properties. When this was melted with sodium sulphide, a dyestuff was formed, giving fast shades on cotton varying according to the amount of colour employed from a light fawn to a brown black. The benzene extract consisted mainly of hydrocarbons having high boiling points and representing complex mixtures. The soot after extraction still possessed a brownish-black colour due possibly to the presence of a considerable amount of ash. In this condition it is highly inflammable, taking fire spontaneously when heated to 100° C., and is then difficult to extinguish. The percentages of constituents estimated directly were: Ammonium sulphate, 10.7; mineral matter (ash), 10.9; acid constituents, 10.9; benzene extract, 13.0; difference (carbon ?), 45.8. London soot contained considerably less extractive matter than Manchester soot, the difference being most noticeable in the small amount of benzene extract (1.3 per cent.). A sample of soot from Prague (lignite coal) gave a neutral aqueous extract. The acid extract contained only traces of ammonium

enzene extract only amounted to 0.2 per cent. The amount of acid constituents soluble in sodium hydroxide per cent.—D. B.

Effect of Liquid Air on Germination of —. Beequerel. Comptes rend., 1905, **140**, 1652—1654.

observers have concluded that exposure to cold to -250° C.) arrests vital processes, and that living may be preserved indefinitely at these low temperatures in a dormant state, ready to recover its original on being thawed. The author concludes from experiments that the effect of low temperatures depends on the amounts of moisture and of gas the seeds contain. If these amounts be sufficient, exposure to cold disorganises the protoplasm through the physical effects of freezing and contraction; but if the seeds are thoroughly desiccated, exposure to cold produces no effect on them—there is no more evidence of "arrest" of vital processes in the cold seed than in the desiccated seed at the ordinary temperature. Proof of this "arrest" may only be possible after exposure to cold for a period long the longest period recorded during which dried seeds at the ordinary temperatures have preserved their power of germinating when submitted to suitable conditions.—J. T. D.

Explosive Antimony; Physico-Chemical Studies on —. Lohsen and T. Strengers. Z. physik. Chem., 1905, **52**, 1—170.

The authors have made an exhaustive investigation of the conditions under which so-called explosive antimony is formed, and of the behaviour of ordinary antimony, explosive antimony, and exploded antimony, i.e., the product after the explosion. By the electrolysis of solutions of antimony tri-bromide and tri-iodide, of whatever concentration, explosive antimony is always formed. In the case of antimony tri-chloride, on the other hand, explosive antimony is only produced when the concentration is above the limits 10—86 per cent. With solutions containing less than 10 per cent. of antimony trichloride, another product is obtained, to which the name non-explosive antimony has been given. Solutions of antimony tri-bromide always yield pure antimony on electrolysis. According to the authors, explosive antimony is a solid form of antimony trichloride, tribromide, or tri-iodide; antimony, the latter being a meta-stable form of ordinary antimony. Exploded antimony and non-explosive antimony are solid solutions of antimony tri-bromide, tribromide or tri-iodide in ordinary antimony. It is found that if the explosive antimony deposited by electrolysis of an 18 per cent. solution of antimony tri-iodide, were exploded whilst still in the electrolyte, non-explosive antimony was deposited on continuing the electrolysis.—A. S.

New Books.

DEUTSCH-CHEMISCHES JAHRBUCH, 1903. Ein Bericht über die Fortschritte auf dem Gebiete der chemischen Wissenschaften. Herausgegeben von Dr. RUDOLF BIEDERMAN, 26ter. Jahrgang. Friedrich Vieweg und Sohn. Braunschweig, 1905. Price, M.15.

This volume, containing 567 pages of subject matter, and alphabetical indexes of authors' names and subjects, and, as a Register of Patents. The text contains 33 illustrations. The Report, dealing with the advance of Chemical Technology, embraces the subjects under the following heads:—I. Iron. II. Aluminium, &c. III. Gold and Silver. IV. Copper. V. Zinc. VI. Lead. VII. Nickel, Manganese and Chromium. VIII. Tin, &c. IX. Sulphur and Sulphuric Acid. X. The Alkali Industry. XI. Electrochemistry. XII. Ammonia and Cyanogen Compounds.

XIII. Alkaline Earths, &c. XIV. Gases. XV. Phosphorus, Boron, Silicon and Carbon. XVI. Glass. XVII. Earthenware and Porcelain. XVIII. Cements and Artificial Stone. XIX. Explosives and Matches, &c. XX. Illuminants. XXI. Fuels. XXII. Sugar. XXIII. Starches, Dextrin and Starch Sugar. XXIV. Fermentation Industries. XXV. Fats, Soaps and Resins. XXVI. Etheral Oils and Scents. XXVII. Water. XXVIII. Foodstuffs. XXIX. Organic Products. XXX. Albuminoids. XXXI. Dyestuffs. XXXII. Textile Fibres. XXXIII. Paper. XXXIV. Photography. XXXV. Tanning and Glue, &c. XXXVI. Manures, Fertilisers, and Disinfection. XXXVII. Apparatus. XXXVIII. New Book Reviews.

Trade Report.

I.—GENERAL.

MEXICO: TRADE OF —.

For. Off. Ann. Series, No. 3429.

The value of certain articles of export from Mexico are as follows:—

Articles.	1901-02.	1902-03.	1903-04	July 1 to Dec. 31, 1904.
Gold	£ 911,525	£ 1,420,877	£ 1,072,644	£ 659,973
Silver	5,963,251	7,755,467	7,907,489	2,996,284
Copper	1,684,983	2,012,233	2,323,421	3,656,197
Lead	573,084	566,907	482,564	1,440,157
Other metals	54,677	118,178	135,898	52,340
Dye-woods	128,877	96,401	84,755	54,300
Raw hides	628,657	746,648	655,408	309,215

The subjoined table shows the value of certain articles imported into Mexico:—

Articles.	1902-03.	1903-04	1904. (2nd half)
Mineral products	£ 4,803,284	£ 4,497,495	£ 2,083,174
Chemical and pharmaceutical products	558,325	631,641	296,706
Spirits, natural, and artificial fermented liquors	626,848	678,604	305,922
Paper and manufactures of paper	385,072	467,290	220,162
Machinery, &c.	2,067,417	2,124,495	967,656
Arms and explosives	359,262	435,922	188,271

PORTUGAL: CHEMICAL IMPORTS INTO —.

For. Off. Ann. Series, No. 3418.

The imports of chemicals through Oporto during the years 1900-04 were as follows:—

	Quantity.				
	1900.	1901.	1902.	1903.	1904.
Alkalis, caustic, solid or liquid	Tons. 681	Tons. 679	Tons. 725	Tons. 691	Tons. 660
Nitrate of potash (saltpetre)	224	265	202	312	317
Chloride of calcium	328	286	432	459	327
Sulphate of sodium, of potash, of copper and of iron	835	700	1,026	1,812	2,566
Carbonate of soda, crystallised or refined, dry	442	494	557	614	558
Dye extracts	806	909	1,128	1,071	1,318
Chemical products not specified	1,439	1,089	1,309	2,026	2,698

III.—TAR PRODUCTS, PETROLEUM, Etc.

PETROLEUM IN ROUMANIA.

For. Off. Ann. Series, No. 3432.

Official statistics show an output of 497,000 tons of petroleum during 1904. The monthly average of 1904 was 37,176 tons during the first half year and 45,635 tons during the second half. Of the four oil-bearing districts of Roumania, the district of Prahova is the richest, the total output of this district showing 455,354 tons against 26,234 tons in Pambovitzu, 8236 tons in Buzen and 7064 tons in Bacau. The number of hand wells have increased owing to their small cost. Official figures show 744 wells in 1904 against 675 in 1903, and those in process of sinking 195 against 163. On the other hand the number of productive borings has decreased, the figures being 290 for 1903 against 224 in 1904. The borings under drill have, however, increased from 114 to 192.

The year under review records the most noteworthy events in the history of the petroleum industry of Roumania. German capital played a large part—the three German banks, Deutsche Bank, Disconto Gesellschaft and the Schaffhausen Bankverein being the mediums through which fresh companies were formed and old ones supported.

The exports of petroleum from Roumania during the years 1899–1903, together with the exports to the United Kingdom, were as follows:—

Year.	Total.		To United Kingdom.	
	Quantity. Tons.	Value £	Quantity. Tons.	Value £
1899	62,109	395,558	4,155	16,633
1900	72,700	386,519	20,916	102,192
1901	42,600	237,694	12,676	83,400
1902	68,772	129,739	21,354	42,210
1903	103,962	171,092	31,836	38,440

IX.—BUILDING MATERIALS, Etc.

CEMENT MANUFACTURE IN ROUMANIA.

For. Off. Ann. Series, No. 3432.

Two cement factories exist in Roumania, one in Braila and the other in Cernavoda. The former produced 10,500 tons, 1150 tons of which went to Egypt, 550 tons to Bulgaria and 10 tons to Greece. The remainder was used in the country. The firm is registered under the name *Fabrica de Cement Portland, Braila*. In Cernavoda there exists the *Société Anonyme des Ciments Portland de l'Europe Oriental*, the head office of which is in Antwerp. Last year the firm exported 250 tons to Turkey via Constantza.

MAGNESITE BRICK; U.S. CUSTOMS DECISION.

June 19, 1905.

The Treasury Department has appealed to the United States Circuit Court the decision of the Board of General Appraisers of June 7, 1905, which held bricks made from magnesite to be dutiable at 1 dol. 25 c. per ton as "fire brick," under paragraph 87 of the tariff. The Department considers the issue of importance and maintains the assessment of duty at 25 per cent. *ad valorem*.

—R. W. M.

LUMBER: FIREPROOFED —. U.S. CUSTOMS DECISION.

June 8, 1905.

The United States Circuit Court rendered a decision on fireproofed lumber making it dutiable as a "manufacture

of wood" at 35 per cent. *ad valorem*, under paragraph 87. The lumber in question was ordinary sawed lumber which had been treated with phosphate and sulphuric acid in a closed vessel to render it fireproof. The Board of General Appraisers sustained the contention of the importers that it was dutiable as sawed lumber at 2 dol. per 1000 ft. This was reversed by the Court which held that it has by reason of the treatment become a new article and dutiable as a manufacture.

—R. W. M.

X.—METALLURGY.

MINERAL PRODUCTION OF QUEENSLAND.

Ibid. of Trade J., July 6, 1905.

The following details are extracted from the Annual Report of the Under Secretary for Mines on the Queensland Mining Industry for 1904.

The value of last year's mineral production was 3,704,241*l.*, an excess over that of the preceding year of 18,148*l.*, and thus the largest hitherto recorded. The yield of gold has fallen off to the extent of 124,800*l.*, copper shows a deficiency of 27,226*l.*; lead of 19,000*l.* and, although silver, tin and coal have advanced, the value of these metals has been more than receded, last year's pre-eminence is really due to a large increase in the quantity of wolfram mined, the higher price obtained for that mineral. The serious decline is in the gold yield, which of late years has maintained so high a level. The greater part of the year's supply of silver and lead came from the Charters Towers smelters, which during the twelve months produced 357,196 ozs. of silver and 1661 tons of lead, the furnace being chiefly fed by the Girofla Mine, at Mount Morgan, and by the Crooked Creek Silver-lead Mine, near Alderton. By far the largest quantity of Queensland tin is produced from the lodes of the Herberton district, and of these the Vulean, at Irvinebank, still maintains its supremacy. A drive from the 900 ft. level in this mine encountered a large body of good ore, and has, for a distance of 100 ft., been extended through what appears to be a solid mass of ore estimated to contain 12 per cent. of black tin. The actual dimensions of the body have yet to be determined by means of crosscuts, but the discovery is important as showing that here, as in older tin-mining countries, the ore persists at a depth.

Despite a deficiency of 27,226*l.* in the value of last year's production, the outlook for copper mining is promising, and the current year should witness a considerable expansion of this branch of the industry. The largely increased consumption of wolfram in the manufacture of high-grade steel has created a demand that has met with a ready response in Queensland. The northern portion of the State appears to be one of the principal sources of the world's supply of the mineral, and, while the total output from 1894, when any record of wolfram first appears in reports, up to the end of 1903, was 996 tons, valued at 30,894*l.*, last year's production, from the figures furnished by the Wardens, reached 1539 tons, of a value of 161,635*l.*, the value of the wolfram ore actually exported during the same period being returned by the Customs at 96,000*l.* Although the manufacture of manganese is by no means of rare occurrence in Queensland, the very limited local demand for the metal, and the difficulty of establishing an export trade in the face of the competition from the Caucasus and elsewhere affords small encouragement to attempt the development of the numerous manganese deposits that are to be found in the southern and central parts of Queensland. The only local market is the Mount Morgan Mine, and the requirements of the company are supplied by the Mount Miller Mine, at Gladstone, which last year produced 830 tons of manganese, valued at 3540*l.*

Last year's production of coal reached 512,000 tons, valued at 166,531*l.*, an increase in quantity of 4,200 tons, and in value of 1538*l.* The principal coalfield in the State

the Ipswich district, and it is from these mines that increased production has been derived.

BRITISH COLUMBIA; MINERAL PRODUCTION OF —, IN 1904.

Bd. of Trade J., June 29, 1905.

The following figures showing the output of minerals in British Columbia, for the year 1904, are taken from an annual report of the Minister of Mines. Figures for 1903 are added for purposes of comparison:—

	1903.		1904.	
	Quantity.	Value.	Quantity.	Value.
Copper, ozs.	53,021	1,060,000	55,765	1,115,000
Lead, " "	232,831	4,813,000	222,042	4,580,000
Iron, " "	2,996,204	1,521,000	3,222,481	1,720,000
Fluorine, lb.	34,359,921	4,547,000	35,710,128	4,578,000
Gold, " "	18,089,283	690,000	36,646,244	1,422,000

ORES EXPORTED FROM NEW CALEDONIA.

For. Off. Ann. Series, No. 3431.

The subjoined table shows the amount of ores exported during the years 1899-1904:—

Year.	Quantity.		
	Nickel.	Chrome.	Cobalt.
	Tons.	Tons.	Tons.
1899	101,909	12,635	3,287
1900	101,319	10,474	2,438
1901	132,814	17,451	3,122
1902	129,365	10,281	7,512
1903	77,360	21,437	8,292
1904	98,655	21,437	8,964

In 1903 nine tons of copper and five tons only of lead were exported, and none in 1904. At one time the export of two minerals was more important. Slight traces have been discovered, but never in any paying quantity. The very varied mineral riches of New Caledonia have as yet hardly been touched for want of outside enterprise and capital.

MINERAL EXPORTS FROM MEXICO.

For. Off. Ann. Series, No. 3429.

In the fiscal year 1903-04 gold to the value of 125,713*l.* was exported in excess of the previous year, and in the half of 1904 *£*87*l.* more than during the corresponding period of the previous year. The increase in the value of silver in 1903-04 over 1902-03 amounted to 8*l.*, but during the latter half of 1904 there was a decrease under the corresponding period of the same year.

The value in Mexican currency of the silver exports from July 1 to December 31 in 1903 and 1904 are as follows:—

	1903.	1904.
	Dollars.	Dollars.
Mexican silver dollars	12,143,337 0	6,747,272 0
Foreign silver coins	42,476 0	17,441 0
Silver bars	24,545,018 66	24,186,000 39
Silver slimes, &c.	6,894,274 8	5,007,000 7 39
Total	43,625,105 74	29,967,720 3

Exports of copper during recent years were: 1899-1900, 28,266 metric tons; 1900-01, 33,351 metric tons; 1901-02, 61,864 metric tons; 1902-03, 62,132 metric tons; 1903-04, 80,286 metric tons. (See also under Class I., p. 819).

With the introduction of modern metallurgical methods Mexico will probably export fewer ores than heretofore, and there will be more and more treated in the country. Since the development of mining in the United States and elsewhere, new methods have gradually been introduced all over Mexico. There are about 90 smelters for the reduction of precious metals to-day in the Republic, the most important of which is that situated about 4 miles from Aguascalientes, employing several hundred men, with an annual consumption of about 150,000 tons of ore. The others are those of Monterrey, San Luis Potosi, Mapimi and Parral.

PLATINUM: PRODUCTION OF — IN RUSSIA. W. A. Dyes. Chem. Ind., 1905, 28, 378-381.

Notwithstanding an increased supply in recent years, platinum has become considerably dearer, the price during 1904 ranging from 16,000 to 19,000 roubles per pound (1 rouble=3*s.* 2*d.*; 1 pound=36 lb.). Both the price and production (95 per cent. of the total) of Russian platinum have fluctuated considerably, as is shown in the following table:—

Year.	Price.	Production	Year.	Price.	Production.
	Roubles.	Pouids.		Roubles.	Pouids.
1869	1,600	140-0	1893	—	311-3
1874	—	120-0	1894	—	318-0
1882	—	250-0	1895	—	269-5
1890	12,000	270-0	1896	—	301-0
1891	5,000	258-6	1897	—	342-0
1892	7,000	279-2	1898	13,000	267-0

In 1900, the production was 310-7, and in 1901, 389 pounds, whilst during the period 1899-1904, it averaged 350 pounds. The increased production of 1901 has not been maintained, owing chiefly to two reasons. In the first place the greater number of the more important mine-owners are bound by contracts covering a period of 10 years, whereby, whatever be the price of platinum in the markets of the world, they have to deliver their product to the large refining firms at a fixed price of 10,000 or 11,500 roubles per pound. These mine owners, not being in a position to receive any advantage from the rise in price of the metal, have, therefore no inducement to increase the supply. The second cause of the gradual decrease in the production of platinum lies in a diminution of the yield of the richer mines. In 1900, the maximum platinum content of the ore was 15-68 grms. per 1,000 kilos., but in 1901 the corresponding figures were only 5-89 grms. per 1,000 kilos. In 1900, 100 firms, and in 1901, 120 were engaged in platinum mining in Russia. The mines are all situated in the Government of Perm, in three districts, of which Gorablagodatj produced 193-4 pounds in 1901 (118 in 1900), Krestowosdwichensk 98-8 pounds (99 in 1900), and Mischnetagilsk 71-8 pounds (76 in 1900). (See also this J., 1890, 1077; 1892, 532; 1894, 995; 1898, 1,083; 1904, 567, 1169).—A. S.

XII.—FATTY OILS, FATS, Etc.

GREASE; SOLUBLE ——. U.S. CUSTOMS DECISION.

The Treasury Department has decided to take no further action in the case of soluble grease recently decided by the Circuit Court to be dutiable at 20 per cent. *ad valorem*, under Section 6 of the tariff, as a "manufactured article unenumerated." The article is a sulphomated grease, used in finishing, and was claimed by the Government to be dutiable at 30 per cent. *ad valorem*, as an "alizarin assistant," under paragraph 32.—R. W. M.

DISTILLED OIL—WOOL OIL; U.S. CUSTOMS DECISION.

June 23, 1903.

An article variously known as "wool oil," "pure oleine," and "pure oleine grease" is dutiable at 25 per cent. *ad valorem*, under the provisions of paragraph 3 of the tariff for "expressed, rendered and distilled oils." The analysis of the sample was as follows:—Sp. gr. (15° C.), 0.9085; free fatty acids, 53.90 per cent.; neutral fat, 1.32 per cent.; unsaponifiable matter, 44.78 per cent. The claim of the importer that it was free of duty, under paragraph 568, as a "grease used only for wire drawing or stuffing or dressing leather," was overruled, as it was shown that it was also used for lubricating and dressing wool. The further claim that it was dutiable at 1 c. per lb., under paragraph 279, as "wool grease," was also overruled, on the ground that the process of distillation which it had undergone had destroyed its character as wool grease and produced a new article.—R. W. M.

SESAME OIL; U.S. CUSTOMS DECISION.

June 1, 1905.

The United States Circuit Court decided that ground sesame seed or sesame pulp from which the oil has not been extracted is free of duty as "sesame oil" under paragraph 626 of the free list of the tariff. The assessment of duty at 20 per cent. *ad valorem* as a "manufactured article unenumerated" under Section 6 was overruled on the ground that it is commercially known as sesame oil, although a more refined product is also known under the same name.—R. W. M.

XIII. C.—INDIA-RUBBER, Etc.

GUTTA-PERCHA AND RUBBER TRADE OF SINGAPORE.

U.S. Cons. Rep., No. 2296, June 29, 1905.

Gutta-percha exports to the value of 6,570,000 dols. were shipped from Singapore in 1903, coming chiefly from Dutch North Borneo, Penang, and Sumatra, and a smaller amount from the Sulu Archipelago. Of the amount exported, 3,891,464 dols. worth went to Great Britain, 2,213,619 dols. worth to Germany, and 207,131 dols. worth to the United States. The statistics for 1904 are not yet complete. In 1903 Singapore exported 236,297 dols. worth of india-rubber (nearly all to Great Britain) and 1,108,989 dols. worth of Borneo rubber, of which 336,121 dols. worth went to Austria, 372,922 dols. worth to the United States, 216,150 dols. worth to Great Britain, and smaller amounts to Japan, France, Italy, and Germany. The shipments of Borneo rubber during 1904 have considerably increased.

XVI.—SUGAR, STARCH, GUM, Etc.

SUGAR PRODUCTION OF MEXICO.

For. Off. Ann. Series, No. 3429.

The production of molasses in Mexico during the year 1903-04 was 69,418 metric tons, and of sugar, 107,547 metric tons. The production of sugar in the Republic

of Mexico during the last five years was:—1899-1900, 75,000 tons; 1900-01, 95,000 tons; 1901-2, 103,000 tons; 1902-03, 112,000 tons; 1903-04, 107,000 tons.

As will be seen by this statement there has been a shortage in the production of 1903-04 on that of 1902 of about 5000 tons, due to the fact that in the State of Morelos there was a shortage of about 4000 tons at Oaxaca about 2000 tons, but on the other hand Pi increased 1000 tons. It is feared that owing to continual rains which have fallen during the whole of the latter part of 1904 and also during the first part of 1905 this crop will also be a short one. The estimate of this year's crop is put down at 115,000 tons.

Much of the sugar from the State of Morelos has been exported to the United Kingdom, and Morelos now fetches a good price in the local market, from 13 to 14 per arroba (38. per 25 lbs.).

SUGAR PRODUCTION OF ROUMANIA.

For. Off. Ann. Series, No. 3432.

At present there are five sugar refineries in Roumania, viz., Roman, Marasesti, Chitila, Repiceno (Botc Săcut, and their annual output is said to be from 100 to 20,000 tons. About 75 per cent. of the sugar is refined and the remainder crushed and in loaves, the labour employed on the beet-fields is mostly from large percentage being Hungarian. The men receive 1 fr. 50 c. to 1 fr. 60 c. per day, and the girls employed in cutting up beet receive 70 to 80 c. In order to prevent the present refineries the Government have decided to grant no further licenses for new enterprises. The crop for 1904 equalled only about two-thirds of that of 1903. The figures were:—1900, 236,580 tons; 1901, 254,780 tons; 1902, 130,830 tons; 1903, 208,480 tons; 1904, 145,090 tons.

XVII.—BREWING, WINES, SPIRITS, Etc.

BREWING AND DISTILLING IN JAPAN.

U.S. Cons. Rep., No. 2291, June 23, 1905.

The only distilled liquor produced in Japan is "shochu," distilled from rice, just as the natural beverage "sake" is brewed from the same material. The product is called "shochu" for 1902 amounted to 5,161,000 galls., is rather difficult to ascertain the number of the distilleries, as the liquor is generally manufactured by the brewers as a side line. Distilling is conducted in the old-fashioned style. No distillery of foreign spirits, whisky and brandy, has yet been started in Japan. In recent years the manufacture of spurious foreign spirits by the mixture of alcohol has prevailed, but owing to the imposition of a heavy import duty on alcohol the business has undergone a check.

In 1902 there were fifteen small manufacturing distilleries of alcohol, the total output amounting to only 5888 galls. There are more than 20,000 "saké" brewers in the country, and the consumption of "saké" from the Government derives a large revenue, does not diminish, despite the gradual increase of tax on the output of "saké" in 1902 was 160,433,258 galls.

Until about fifteen years ago there were only one or two beer breweries in Japan, but in 1902 the number had increased to seven. The output of beer in 1902 was 3,614,526 galls. The rapidity with which the consumption of beer has increased among the Japanese is remarkable. At first all the breweries were getting their supplies of malt from abroad, but at present several breweries are making malt from Japanese barley.

SPIRITS; EXCISE DUTY ON FOREIGN — IN CAPE COLONY.

Bd. of Trade J., July 6, 1905.

The Cape of Good Hope Government Gazette for 2nd June last contains the "Additional Taxation Act, 1905" (No. 26 of 1905), which was assented to on 1st June 1905.

et in question provides than an Excise Duty of proof gall.* shall be imposed, with effect from June, 1905, on foreign spirits sold, removed or d of in Cape Colony. The term "Foreign Spirits" include spirits manufactured in any Colony or Territory under the Customs Union from the growth or produce of any Colony or Territory.

duty is increased proportionately if the strength is above

XX.—FINE CHEMICALS. Etc.

CITRAL; A NEW SOURCE OF —.

Chem. and Druggist, 1905, 67, 17—18.

At present time nearly the whole of the lemon-grass essence comes from the native States of Travancore and Cochin, the annual exports from these States being in 3000 cases. A slight falling off in the exports of Cochin is shown in the latest returns, the figures for 1904 and half of 1904 being 1340 cases, as compared with 136 and 1490 cases in the corresponding periods of 1902. Lemon-grass is grown in Ceylon, but its output is small. At a recent meeting of the Agricultural Society in that island, Mr. H. Wright stated that grass and citronella can be cultivated successfully to a elevation of 2000 ft. in the Central Province, and in some cases better yields of oil being obtained from the more low-lying places in the south and South-Western provinces. In view of the high price of lemon-grass, endeavours have been made to find a substitute for it as a source of citral for the manufacture of ionone. The essential oil of *Backhousia citriodora* containing 10 per cent. of citral (see this J., 1905, 689, 749) would be quite satisfactory in this respect if regular supplies can be furnished.—A. S.

BERGAMOT OIL.

Oil and Colourman's J., July 1, 1905.

The yield of bergamot oil this season is only from 40 to 50 per cent. of that of last season, hence the rapid rise in price. The ester value is not more than 35 to 38 per cent. except in a few isolated cases, when 38 to 40 per cent. is reached. The future position of this oil depends on the next flowering, which will very possibly be scanty.

Patent List.

—In these lists, [A.] means "Application for Patent," and [C.S.] means "Complete Specification Accepted."

A Complete Specification accompanies an Application, and is affixed. The dates given are (i) in the case of Applications for Patents, the dates of application, and (ii) in the case of Complete Specifications Accepted, those of the Official Journals of acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to opposition at the Patent Office immediately, and to opposition two months of the said dates.

PLANT, APPARATUS, AND MACHINERY.

A 3,805A. Massey (Massey-Harris Co., Ltd.). Liner for centrifugal separators. July 8.

13,763. Lane. Furnaces. [U.S. Appl., July 5, 1904.]* July 4.

- [A.] 14,092. Liddiard. Construction of a class of vessels for distilling and other purposes.* July 8.
- " 14,099. Hatmaker. Concentrating or drying liquid mixtures or solutions of inorganic substances. July 8.
- " 14,278. Royle. Mode and apparatus for drying peat and other mixtures of solids and liquids. July 11.
- " 14,327. Moll. See under VII.
- " 14,379. Boulton (Milwaukee Evaporator Co.). Evaporating apparatus.* July 12.
- " 14,413. Humphrey. Apparatus for charging fluids with gases. July 13.
- " 14,572. De Laval. Processes for obtaining a violent chemical reaction between materials and apparatus therefor. [Appl. in Sweden, July 19, 1904.]* July 14.
- " 14,584. Glassford. Apparatus for separating liquids of different densities. July 15.
- [C.S.] 15,776 (1904). Ogle, and the Cyanide Vacuum Filter Co. Apparatus for the separation of liquids from solids, particularly applicable to the extraction of metals from their ores. July 19.
- " 16,652 (1904). Challis. Filters, filtering media, and matters appertaining thereto. July 12.
- " 19,092 (1904). Duckworth. Apparatus for mixing granulated, powdered, or similar substances or fluids. July 12.
- " 865 (1905). Gayley. Method of extracting moisture from air and other gases for use in the arts. July 19.
- " 4369 (1905). Wolff. See under IX.

II.—FUEL, GAS, AND LIGHT.

- [A.] 11,971A (1904). Clay. Production of combustible fluids for power purposes. July 13.
- " 12,160A. Eveno. See under XI.
- " 13,826. Hutelins. Producer gas generators. July 5.
- " 13,914. Connell, Haldane and Thomson. Treatment of the liquid distillery refuse known as "pot ale" or spent wash, brewery yeast, and the like for the production of fuel therefrom. July 5.
- " 14,061. Shrewsbury. Process for producing compressed non-porous briquettes or blocks of coke. [U.S. Appl., Aug. 15, 1904.]* July 7.
- " 14,090. Towns. Gas producers.* July 8.
- " 14,098. Anderson, and Kynoch, Ltd. Suction gas producers. July 8.
- " 14,137. Jouques. Manufacture of briquettes from coal dust. July 8.
- " 14,264. Griffin. Suction gas apparatus. July 11.
- " 14,334. Illy. Apparatus for supplying and vaporising water for gas generators.* July 11.
- " 14,405. Gasmotoren-Fabr. Deutz. Production of motor fluid for gas turbines from bituminous coal. [Ger. Appl., July 13, 1904.]* July 12.
- " 14,414. Lachomette. Coking ovens. July 12.
- " 14,485. Coppée. Regenerative coke ovens. July 13.
- " 14,498. Fielding. Gas producers. July 14.
- " 14,575. Foster and Greener. Gas producers. July 14.
- [C.S.] 18,975 (1904). Roberts and Anstey. Apparatus for the manufacture of generator gas. July 19.
- " 19,183 (1904). Brotherhood. Producer gas manufacturing apparatus. July 19.
- " 22,917 (1904). Oliphant and Scott. Apparatus for converting oil into gas. July 19.

- [C.S.] 351 (1905). Wagner. Process for the preparation of compounds for fuel briquettes. July 19.
 „ 1816 (1905). W. and J. George, Ltd., and George. *See under VII.*

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

- [A.] 14,294. Fell (Korndörfer). Manufacture of emulsifying mineral oils and mineral oil-soaps. July 11.

IV.—COLOURING MATTERS AND DYESTUFFS.

- [A.] 13,804. Ransford (Cassella and Co.). Manufacture of polyazo colours. July 4.
 „ 13,950. Lake (Oehler). Manufacture of brown sulphur dyes.* July 6.
 „ 14,189. Tompkins. Production of indigo and indigo producing substances. July 10.
 „ 14,543. Inray (Meister, Lucius und Brüning). Manufacture of red, dark red to violet sulphurised dyestuffs. July 14.
 „ 14,578. Johnson (Badische Anilin und Soda Fabrik). Manufacture of new raw materials of the anthracene series and colours therefrom, and their application in dyeing and printing. July 14.
 „ 14,618. Nuth, Hold and Ruegg. Process for the preparation of new raw materials and of new azo dyestuffs. [Fr. Appl., July 16, 1904.]* July 15.
 [C.S.] 23,072 (1904). Newton (Bayer and Co.). Manufacture of new tetraazo dyestuffs. July 19.
 „ 82 (1905). Inray (Soc. Chem. Industry in Basle). Manufacture of azo dyestuffs for wool. July 19.
 „ 12,854 (1905). Johnson (Badische Anilin und Soda Fabrik). Production of indigo. July 12.

V.—PREPARING, BLEACHING, DYEING, PRINTING AND FINISHING TEXTILES, YARNS, AND FIBRES.

- [A.] 13,714. Henry. Processes of cold dyeing especially by means of new pigmentary and interferential colours.* July 3.
 „ 13,952. Soc. Schmid Frères. Process and apparatus for ungumming, bleaching and dyeing silk. [Fr. Appl., July 27, 1904.]* July 6.
 „ 14,023. Sorek. Chemical colour printing process. July 7.
 „ 14,193. Brown and Young. Impregnating or coating goods or material with a liquid or semi-liquid substance. July 10.
 „ 14,202. Abel (Act.-Ges. f. Anilinfabr.). Dyeing hairs. July 10.
 „ 14,480. Nitritfabrik Ges. m.b.H. Process for mordanting wool. [Ger. Appl., July 14, 1904.]* July 13.
 „ 14,626. Castle. Filling and finishing textile fabrics, also applicable to the sizing of yarns. July 15.
 [C.S.] 16,313 (1904). Boulton (Poisson). Method of retting and washing textile fibres. July 19.
 „ 18,742 (1904). Kraus, and the Bradford Dyers' Association, Ltd. Nitrocellulose solutions for use in the treatment of fabrics. July 12.
 „ 2192 (1905). Lacroix. Manufacture of artificial silk. July 12.

- [C.S.] 4534 (1905). Denis. Apparatus for producing threads from collodion and recovering solvents employed. July 19.
 „ 6199 (1905). O'Kassa. Washing and soaping machines. July 19.
 „ 10,448 (1905). O'Brien (L'Huillier). Apparatus for dyeing yarns in cops and pirns. July 19.

VI.—COLOURING WOOD, PAPER, LEATHER,

- [C.S.] 19,989 (1904). Nusch (Sorel). Dyeing process for skins for glove making and other uses. July 19.

VII.—ACIDS, ALKALIS, AND SALTS.

- [A.] 13,619. Holloway. Process for the production of zinc oxide from solutions of zinc salts. July 11.
 „ 14,282. Peel. Apparatus for slaking and deliming. July 11.
 „ 14,327. Moll. Apparatus for evaporating and at the same time producing high pressure steam.* July 11.
 „ 14,409. Bignot. Process and apparatus for extracting arsenious acid from ores. [Fr. Appl., July 1904.]* July 12.
 „ 14,541. Potter. Manufacture of silicon monoxide. [U.S. Appl., Dec. 30, 1904.]* July 14.
 „ 14,573. Howorth (Soc. Anon. Metallurgique cédés de Laval). *See under X.*
 [C.S.] 18,899 (1904). Polnowsky. Manufacture of alkali and alkaline earth carbonates and salts therefor. July 12.
 „ 1816 (1905). W. and J. George, Ltd., and George. Apparatus for generating sulphuretted hydrogen and other gases. July 19.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

- [A.] 13,886. Colloseus. Treatment of blast furnace slag for production of a material similar to concrete.* July 5.
 „ 13,912. Thomson. Manufacture of artificial silicate and lime sand bricks. July 6.
 „ 14,239. Harcastle, and Kay, Bros., Ltd. Composition which forms an emulsion with water to be applied to roads, &c., for preventing dust. July 11.
 „ 14,282. Peel. *See under VII.*
 „ 14,288. Jacobs. Building materials. [U.S. Appl., March 9, 1903.]* July 11.
 „ 14,298. Propper. Artificial building stone. July 11.
 [C.S.] 24,451 (1904). Boulton (Hülsberg und Co.). Impregnation of wood and other porous materials. July 19.
 „ 2467 (1905). Brown. Manufacture of cement, building composition, and articles made from like material. July 11.
 „ 4369 (1905). Wolff. Apparatus for drying bricks, tiles, cement, peat, timber, and like materials. July 19.
 „ 9221 (1905). Thom. Manufacture of artificial marble, dolomite and the like. July 12.

X.—METALLURGY.

- [A.] 13,613. Hobson. Silver alloys.* July 3.
 „ 13,626. Gebauer and Zenzen. Process for raising or modifying the blown molten iron in the converter for cast steel.* July 3.

- 13,687. Chanmet. Alloys applicable for jewellery and for soldering.* July 3.
- 13,811. Davies and Clark. Method of welding iron or steel and of welding or coating them with other metals and fluxes employed for that purpose. July 4.
- 13,955. Zimmer. Apparatus for cleaning and separating minerals. July 6.
- 14,068. Rawson and Eimore. Process for extraction of gold from solutions. July 8.
- 14,330. Richardson. Method of brazing metals. [U.S. Appl., Aug. 1, 1904.]* July 11.
- 14,331. Heskett. Process and apparatus for obtaining metals from their sulphides. July 11.
- 14,365. McLean. Soldering of platinum and platinum alloys by means of platinum. July 12.
- 14,377. Jones, White and Salter. Aluminium solder and flux. July 12.
- 14,573. Howorth (Soc. Anon. Metallurgique Procédés de Laval). Process of extracting zinc or zinc oxide from its ores. July 14.
- 14,574. De Laval. Process of extracting iron from its ores. July 14.
- 15,577 (1904). Nicholas. Recovery of metals from ores and other material. July 19.
- 15,776 (1904). Ogle, and Cyanide Vacuum Filter Co., Ltd. *See under I.*
- 16,028 (1904). Johnson (De Moya). Manufacture of steel. July 19.
- 17,624 (1904). Leisel and Küpper. Material applicable for soldering and coating metals. July 19.
- 17,034 (1904). Esser. Ore concentrators. July 12.

Official Notices.

COMMUNICATIONS.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 43 of the Bye-laws the Society has the right of priority of publication for three months of all such papers. Infringement of this Bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

SIXTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY, ROME, 1906.

The Sixth International Congress of Applied Chemistry will be held in Rome in April, 1906, during Easter week. All communications should be addressed to the President, Prof. E. Paterno, Via Panisperna, 89 Rome.

Changes of Address.

When notifying new addresses, members are requested to write them distinctly, and state whether they are temporary or permanent. Multiplication of addresses is also to be avoided as tending to create confusion. When sending subscriptions, the use of the form attached to the application helps in the verification of addresses, on which the safe delivery of the Journal depends.

Annual General Meeting.

(Continued.)

Dr. W. H. Nichols has received the following reply to the telegram sent to President Roosevelt on the occasion of the Annual Dinner:—

Department of State,
Washington,
July 16th, 1905.

Sir,

I am directed by the President to acknowledge with deep appreciation, the receipt of your telegram of the 12th inst., stating that, at a dinner of the Society, his health, proposed by the Lord Chief of England, had been enthusiastically received and conveying an expression of sympathy in view of the death of the late Secretary of State.—I am, Sir, your obedient Servant,

(Signed) ALVEY A. ALLEN,

Acting Secretary.

To
W. NICHOLS, Esquire,
President, Society of Chemical Industry,
Hotel Russell, London, England.

THURSDAY, JULY 13TH, 1905.

About 250 members and guests of the Society travelled to Haslemere, whence they proceeded to Lythe Hill, where they were entertained by Mr. and Mrs. R. and Garton. The house is beautifully situated, almost on top of Blackdown; from the grounds and cricket field adjoining, magnificent views of the Sussex Weald are obtained. During luncheon, the pipers of the North Highlanders played on the lawn, and the band of the regiment performed a selection of music during the afternoon; a sword dance and Highland reel were also

ed. The American and Canadian members visited the home of the late Lord Tennyson, over which were conducted by Lord and Lady Tennyson. Parties members also went on motor cars to Hindhead and the Punch Bowl, from which points splendid views of the surrounding country were obtained.

In the evening, a reception was given by the President and Council of the Royal Society, at Burlington House, as attended by a large number of members. Among objects of interest on view were busts of King II. (Founder of the Society), King George III., Newton, Faraday, and Davy; portraits of Franklin, Wheatstone, Joule, Faraday, Dalton, Graham, and Davy, and many others. In the principal hall were seen the mace, charter book and original seal of the Royal Society, and examples of books from its library. The following instruments were also displayed:—Air-pump with double barrel, said to have been presented by Boyle in 1662; Huygens' aerial telescope presented in 1671; an object glass of 170 ft. focal length by Huygens; an object glass by the same for a telescope of 210 ft.; a chronometer by Arnold, which accompanied Cook on his second and third voyages; a battery made in a tailor's thimble by Wollaston; a steam machine, constructed by Priestley; original Davy's miners' safety lamp; mountain barometer used by Darwin in his voyage round the world in H.M.S. *Beagle*; apparatus used by Graham in his principal experiments between 1834 and 1866, (i.) tubes with discs of nitrate and hydrophane for experiments on diffusion of gases, (ii.) apparatus used for ascertaining the diffusion of liquids, (iii.) apparatus used in researches on osmosis, (iv.) apparatus used in experiments on osmotic pressure, (v.) apparatus used in experiments on osmotic pressure applied to analysis, (vi.) reser-voir of compressed air by aid of which capillary liquidation in relation to chemical composition was investigated, (vii.) tube atomiser for the separation of gases, (viii.) waterproof silk bag for dialysis of air, (ix.) used in experiments on absorption and dialytic osmosis of gases by colloid septa, (x.) thermometer graduated by half degrees from 36° to 92° F. The apparatus by Andrews, of Belfast, in his experiments on liquefaction of gases, with the aid of which he determined the critical point of carbon dioxide (1869) was also displayed.

In the evening Dr. Wm. H. Nichols presented a portrait of Lord Kelvin, executed on cameo glass, to the Council of the Royal Society, who accepted it on behalf of the society. Lord Kelvin gave many sittings for this portrait.

FRIDAY, JULY 14TH.

CITY CHURCHES. Leader: Mr. THOS. TYRER.

The Charterhouse.

The Master of the Charterhouse, the Rev. Dr. Haig, received the visitors in the chapel, and gave a history of the Charterhouse. The community includes the Master and 55 brethren, or hospitalers. The Charterhouse is no longer a school as in former times, but its revenues have increased to such an extent that, of the original 40, 800 scholars are now educated at the new Charterhouse at Godalming, which is one of the six great public schools of the country. Many old legends, divines, historians, and novelists were associated with the Charterhouse, notably Thackeray, who set the place in his novel, "The Newcombes." Mrs. Brown conducted the party through the residential parts of the Charterhouse which contain pictures and objects of interest closely connected with the Charterhouse. Mr. J. the Registrar, kindly exhibited old documents, letters and letters of Wesley, and others who were associated with the Charterhouse.

St. Bartholomew the Great.

The church was founded much earlier than the Charterhouse. The visitors were received by the Rector, the Rev. Borradale Savory, Bart., and Mr. E. A. Webb, Churchwarden. Mr. Webb described the building and its vicissitudes, the encroachments upon it in the

16th and 17th centuries, and the means taken to restore its original beauty. He then showed the monuments, notably that of Rahero, the founder. Some idea of the encroachments, now removed, may be obtained when one learns that a fringe factory stood over the altar, and a blacksmith's forge occupied a side chapel in which the present rector saw horses regularly shod. The crypt has been recently cleared, and now serves as a mortuary chapel.

Thence the party proceeded to St. Bartholomew's Hospital, passing on the way the spot where the Martyrs were burned at the stake, and in memory of which a tablet has been placed on the wall of the hospital. The noble staircase is adorned by Hogarth's pictures illustrating the life of Rahero, mentioned above, and the Hall contains portraits of celebrated physicians and surgeons, and notably one of H.M. the King, presented by himself, on retiring from the presidency of the hospital.

St. Giles', Cripplegate.

The Rev. Prebendary Barff, M.A., conducted the party over the church, which has been thoroughly restored. A notable alteration has been made in the north front of the Church by the removal of old shops and the ancient Quest House. The roadway has been thereby widened and on part of the space or forecourt, a statue of Milton—who was buried within the Church—has been erected. The monuments and archives contain an entry of the marriage of Cromwell, and register of Milton's burial. The register of burials during the plague is marvellous for its clearness and accuracy, seeing that more than 2,500 burials took place in one month in the churchyard. The churchyard also contains a complete bastion of the ancient City Wall.

Luncheon was taken at the Guildhall Tavern, after which the party joined another group at the Guildhall.

(2) **THE OLD CITY.** Leader: Mr. BRYAN CORCORAN.

The interesting sights included St. Magnus the Martyr (the passage still under this tower formerly led on to old London Bridge); the Monument; the wholesale Fruit Market; Billingsgate Fish Market in full swing (among the congested narrow lanes in a secluded court, Sir Christopher Wren's house still exists); Coal Exchange, where Roman remains are preserved; the spire of St. Dunstan's in the East; and the Custom House. The party drove by way of Lower Thames Street, past Galley Quay to the Tower of London, where they were received by General Sir Hugh and Lady Gough at St. Thomas' Tower, and afterwards conducted round the special sights in the Tower; then across Tower Hill to a portion of the old City Wall, along Cooper's Row and Crutched Friars, to another part of the Wall, now being partially pulled down, where samples of Roman materials 2,000 years old were provided for visitors to take away with them; St. Olave's, Hart Street (Pepys' Church) where the party was received by the Rector, the Rev. A. B. Boyd Carpenter, M.A. The very interesting monuments were explained by Mr. Corcoran and Mr. T. Pallester Young. The original Gateway of the Old Navy Office, old business premises, and the old Ambassador's house were seen; the party then proceeded to Allhallows Barking (Laud's church), where they were received by the Vicar, the Rev. A. W. Robinson, B.D., who personally described the church, and showed William Penn's entry in the register, &c. The Corn Exchange, in Mark Lane, was seen during its busiest market hours. After inspecting the tower of Allhallows Staining (the church has been pulled down), and lunching at the London Tavern, Fenchurch Street (where the dish and cover used by Queen Elizabeth are still shown), the party drove to Guildhall, where they were received by the librarian, Mr. C. Welch, who showed them the principal objects of interest.

(3) **ST. PAUL'S, WESTMINSTER ABBEY AND THE TOWER.**

Leader: Mr. C. G. CRESSWELL.

Another party attended morning service at St. Paul's Cathedral, after which Archdeacon Sinclair took them to the crypt, in which lie the remains of Sir Christopher Wren,

Lord Nelson, the Duke of Wellington, and many other eminent men. The classic sarcophagus of Nelson was originally made for Cardinal Wolsey and placed in readiness in the Wolsey Chapel at Windsor. Wolsey, however, died in disgrace and was buried at Leicester, and his sarcophagus was used for Henry VIII. When George III. converted the Wolsey Chapel into a burial place for the Guelph dynasty, Henry VIII's body was placed in a tomb more in keeping with the style of the building, and the vacant sarcophagus was sent to St. Paul's and now holds the remains of Lord Nelson. The monuments of Nelson, Wellington, and Gordon in the Nave and of Creighton in the South Choir Aisle were also shown. The party then proceeded to the Tower of London, where they were received by General Sir Hugh Gough, V.C., G.C.B. (Keeper of the Regalia), and Lady Gough at their residence in St. Thomas' Tower. They were shown the regalia, the Bloody Tower and the White Tower, with its fine Norman Chapel, its armouries and dungeons. A visit to the Church of St. Peter ad Vincula, with its memorials of those who perished within the precincts of the Tower completed the survey. The President, Lady Ramsay, and others were afterwards entertained at luncheon by Sir Hugh and Lady Gough. The remainder of the party lunched at the Westminster Palace Hotel, and then proceeded to the Deanery, where they were received by the Dean of Westminster, the Very Rev. Armitage Robinson, who first showed the "Jericho" parlour with its antique stained glass windows, and then the "Jerusalem Chamber," the "withdrawing room" of the Abbots of Westminster. The party next proceeded to the Abbey, and inspected the Chapel and shrine of Edward the Confessor, Henry VII. Chapel, and all the famous monuments, including the tomb where Queen Elizabeth and Queen Mary rest together, and that of Mary Queen of Scots. After a visit to some of the chapels and the Poets' Corner, the party inspected the great and little cloisters and Westminster School, the Great Hall of which once served as the Monks' dormitory.

In the afternoon His Majesty the King received the following gentlemen of the Society of Chemical Industry:—Dr. W. H. Nichols, of New York, President; Professor C. F. Chandler, Columbia University, Past President; Sir William Ramsay, Past President; Dr. E. Divers, President-Elect; Mr. A. Gordon Salamon, Chairman London Section; and Mr. Julian L. Baker, Hon. Sec. London Section.

At 4 p.m. Mr. and Mrs. J. Fletcher Moulton gave a garden party to the members and their friends, at their London residence, 57, Onslow Square, South Kensington, S.W. Afterwards the American Ambassador, Mr. Whitelaw Reid, received a large number of members of the Society at Dorchester House, Park Lane.

In the evening some 200 members paid a visit to the Coliseum, St. Martin's Lane.

SATURDAY, JULY 15.

About 400 members and ladies paid a visit to the works of Messrs. Burroughs, Wellcome & Co., at Dartford, Kent, and were entertained at the quarter century commemoration fête of the Company at the Wellcome Club and Institute, founded for the benefit of the firm's employees. After fire drill, the chemical department with its vacuum stills of two to three thousand gallons capacity, the works office, the boilers, dynamos, and engineers' department, the powdering, compressing, drying, sugar coating, and packing rooms, the photographic, analytical and pharmaceutical departments and the ample works laboratories, were shown in rapid succession.

The tour of the works being completed, carriages conveyed the visitors to the Wellcome Club and Institute, where, after some aquatic sports, luncheon was served in a marquee for both visitors and employees. Mr. Henry S. Wellcome was in the chair, and Mr. R. Clay Sudlow, the General Manager, occupied the vice-chair.

After luncheon, the toasts of "The King," and "The President of the United States," having been duly honoured, the Chairman proposed the toast of "The Society of Chemical Industry," and Dr. Nichols, in

replying, said that Mr. Wellcome had found the philosopher's stone of technical success, in that he not forget those who worked for him. Prof. I. Armstrong, F.R.S., in proposing "Burroughs, Wellcome & Co.," said that the firm had set a great example in helping the cause of science in every direction. Chairman replied. Mr. A. Gordon Salamon proposed toast of "Medicine and Pharmacy," which was read by Sir James Dick and Mr. R. A. Robinson, President of the Pharmaceutical Society.

The rest of the afternoon was taken up with a sports of various kinds, after which Lady Mansel distributed the prizes.

Members and ladies dined together at the Crillon Restaurant, and then spent the remainder of the evening at the Naval Exhibition at Earl's Court.

SUNDAY, JULY 16TH.

On Sunday morning a number of members and ladies took train from Charing Cross to Canterbury. After lunch at the County Hotel, the party made a tour of the city, seeing St. Augustine's Priory and other remaining objects of interest. At 3 p.m. they attended service at the Cathedral, after which they were escorted by the Dean (the Very Rev. Henry Wace) and Canon Holland round the Cathedral and crypt. Some members and visitors were entertained by Mrs. V. de la W. at the Deanery, the remainder going to the Hotel. Afterwards the party returned to town.

Nottingham Section.

Meeting held at Burton-on-Trent, on May 3rd 1900.

MR. J. T. WOOD IN THE CHAIR.

A METHOD OF DETERMINING THE PEPTOLYTIC ACTIVITY OF PEPSIN.

BY JAMES O'SULLIVAN.

The activity of pepsin in dissolving albumin, the presence of acid is the only means we have of measuring this enzyme and at the same time of determining its proteolytic action.

To quantitatively determine the activity of pepsin the methods employed are usually (1) To act upon undiluted egg-albumin in a hydrochloric acid solution, at the end of the experiment to determine the amount of coagulable in the remainder. (2) To act upon coagulated egg-albumin, or blood fibrin, in a hydrochloric acid solution and weigh the undissolved albumin. These methods necessitate filtration from the undigested portion, and for an inquiry relative to proteolysis, I found them unsuitable, as I had to deal with comparative large volumes of liquid varying much in their rate of filtration.

The method I employed to determine the activity of pepsin is, I think, of sufficient interest to bring before the Society. It occurred to me that the albumin, separated from the nitrogen which goes into solution during proteolysis, could be taken as a measure of the activity of pepsin.

In a paper on "The Hydrolytic Functions of Pepsin" (Jour. Chem. Soc. 1892, 927), I pointed out the importance of keeping the yeast in suspension, and in a paper on the "Hydrolytic and Fermentative Functions of Pepsin" (Jour. Fed. Inst. Brew., 1899, 5, 167), I described a specially constructed piece of apparatus, by means of which I was able to conduct two experiments side by side, and also to keep the solutions undergoing either reaction.

or hydrolysis at a constant temperature and continuously stirred.

digestion of albumin by pepsin has, in common with that mentioned, the necessity for keeping the solvent liquid continuously agitated, and at a constant temperature, and the experiments I shall describe in support of the method I employ to determine the activity of pepsin were conducted with the above-mentioned apparatus.

It is obvious that in carrying out experiments, the results of which are based on the quantity of nitrogen that goes into solution by the action of pepsin, the amount of nitrogen in the pepsin itself must be known.

Although I determined the nitrogen in the pepsin, and egg-albumin, it was not necessary except to verify that the process (Kjeldahl's) for determining nitrogen could be relied upon to give a true measure of the amount of albumin which goes into solution. It is evident that if it is required by this method to determine the influence of any solution containing organic nitrogen on peptic digestion, the amount of this in the pepsin must be known.

The determinations of the albumin in the pepsin gave the following results: (1) 21.37 per cent., (2) 21.39 per cent., average, 21.63 per cent.

The determinations of the albumin in the finely divided blood-fibrin gave (1) 85.9 per cent., (2) 87.9 per cent., (3) 88.3 per cent., or an average of 87.4 per cent.

Preparation of Egg-Albumin.—The white of three eggs was carefully separated from the yolk, and the mixture was poured on to a flat-bottomed nickel dish, which was covered with a watch glass and placed level on a water-bath in the cold, and the temperature gradually raised till the albumin was coagulated; it was then allowed to remain on the bath for ten minutes. It is important to cover the albumin with the glass to prevent formation of a hard scum on its surface, which is usually unacted upon by pepsin. Indeed, in my experience, this has a bearing on the digestion of eggs, which are entirely cooked without the shell. After cooling the albumin, about 3 mm. thick, was cut on the dish into pieces with a cork borer 5 mm. in diameter. In this way pieces were obtained of practically equal surface.

Method of Procedure.—In the apparatus already referred to there are two glass cylinders side by side, resting in a water-bath at temperature bath; in each cylinder is a stirrer, driven by an electric motor, whereby their contents are stirred at the same rate. To start an experiment the quantity of hydrochloric acid was poured into the cylinders, and when this attained a temperature of about 1° less than that of the bath, the quantity of pepsin for each experiment was added, and the time of digestion was noted.

During the digestion a definite quantity of "solution" was collected without removing any undissolved albumin in the following manner:—A glass tube of sufficient length to reach to the bottom of the cylinder had one end bent at right angles, and was then connected by a piece of rubber tube with a special piece of apparatus corresponding to a test-tube provided with a double bored and glass tubed rubber stopper. By this means a definite quantity of the solution was drawn into the test tube, and to prevent the dissolved and undissolved albumin from being drawn with the dissolved matter, the end of the glass tube which was immersed in the mixture was restricted to 10 mm. from its end, and this portion was plugged with cotton wool before use. The solution thus collected was removed from suspended matter, and it was easy, when a definite quantity was drawn into the test tube, to stop it by pinching the rubber connection. The solution remaining in the glass tube was then blown back into the cylinder with the plug of cotton wool.

It is well known that acids aid the digestion of albumin by pepsin; one writer, Dr. Gillespie, in his estimable "The Natural History of Digestion," speaks of the digestion of proteids by the action of acids aided by pepsin. I found that four times as much egg-albumin was dissolved by pepsin and hydrochloric acid at 40° C. as by pepsin alone, and that hydrochloric acid alone had scarcely any action on blood fibrin.

The Activity of Hydrochloric Acid and Pepsin on Blood Fibrin.—(a) 1 gm. of fibrin was added to 200 c.c. of hydrochloric acid (0.25 per cent.) and 0.5 gm. of pepsin, and after 30 minutes' digestion there was dissolved 0.877 gm. of albumin, or 67.7 per cent. After removal of 25 c.c. from which the total albumin in solution was deduced, there was dissolved in the next 30 minutes 0.116 gm. of albumin; allowance being made for the proportion of soluble albumin and albumin in the pepsin in the 175 c.c. at the start of the second 30 minutes. In the remaining 150 c.c., after another hour's digestion, there was in solution, allowance being made as before, 0.660 gm. of albumin. It was found, after 2 hours' digestion that there was a slight apparently insoluble portion and the albumin in this was determined by filtering the 150 c.c. and employing the residue for the estimation; it amounted to 0.014 gm. The albumin thus accounted for in the 1 gm. of blood fibrin is as follows:—

	Grm.
Removed in 25 c.c. after 30 minutes digestion	0.085
Removed in 25 c.c. after 60 minutes digestion	0.1016
In solution in 150 c.c. after 2 hours' digestion	0.6600
In residue	0.0140
	0.8606

or 86.06 per cent. in the fibrin against 87.4 per cent. the average it was found to contain.

Is the quantity of albumin dissolved by pepsin-hydrochloric acid from egg-albumin and from blood fibrin in proportion to the amounts of these submitted to its action? To answer this question egg-albumin was employed of which two determinations of its albumin gave (1) 12.79 per cent.; (2) 13.07 per cent.; an average 12.93 per cent.

(b) To 200 c.c. of the hydrochloric acid (0.25 per cent.) and 0.6 gm. pepsin, 5.033 gm. of egg-albumin were added.

(c) To 200 c.c. of the same acid and pepsin 10.066 grms. of egg-albumin were added.

After one hour's digestion there was dissolved in (b) 0.42 gm. of albumin, and in (c) 0.5897 gm. of albumin.

(b) In the 180 c.c. left the amount dissolved in the second hour, allowing for what was already in solution, was 0.0582 gm., and in the 160 c.c. left after this, allowance being made as before, there was dissolved in the third hour 0.1156 gm. of albumin, and in the 140 c.c. left there was dissolved in the fourth hour 0.0183 gm., and in the remaining 120 c.c., after a further digestion of 18 hours, there was in solution 0.4011 gm. of albumin.

An account of the 0.651 gm. of albumin, which the 5.033 grms. of egg-albumin contained and which was dissolved, is as follows:—

	Grm.
Removed in 20 c.c. after 1 hour's digestion ..	0.042
Removed in 20 c.c. after 2 hours' digestion ..	0.0484
Removed in 20 c.c. after 3 hours' digestion ..	0.0642
Removed in 20 c.c. after 4 hours' digestion ..	0.0668
In solution in the 120 c.c. after 22 hours' digestion	0.4011
	0.6225

or 12.37 per cent. in the albumin against the average 12.93 per cent., which it was found to contain.

(c) The albumin dissolved per hour for 4 hours in this experiment was determined in a similar manner to that dissolved in (b), and an account of the 1.302 grms. which the 10.066 grms. of egg-albumin contained, and which was dissolved in the 4 hours is as follows:—

	Grm.
Removed in 20 c.c. after 1 hour's digestion ..	0.0589
Removed in 20 c.c. after 2 hours' digestion ..	0.0878
Removed in 20 c.c. after 3 hours' digestion ..	0.1097
In solution in 140 c.c. after 4 hours' digestion	0.8659
	1.1223

(d) To 200 c.c. of the hydrochloric acid and 0.5 gm. of pepsin 2 grms. of blood fibrin were added, and (e) to a similar solution 1 gm. of fibrin was added.

In 1 hour there was dissolved in (d) 1.687 grms. of albumin, and in (e) 0.8117 gm. of albumin.

From the experiments in which it is shown, by the nitrogen which goes into solution that practically the whole of the albumin is accounted for, I conclude Kjeldahl's process can be used to determine the nitrogen in the soluble products and that this nitrogen, as such, or calculated as albumin ($N \times 6.25$), can be taken as the measure of the proteolytic action of pepsin.

The quantity of coagulated egg-albumin submitted to the action of pepsin does not appear to influence the amount dissolved in the early stage of proteolysis; however, as time goes on the quantity dissolved bears a relation to the initial amount. This is no doubt due to the fact that as the agitation proceeds the pieces of egg-albumin are made smaller by attrition which favours the contact of enzyme, acid and albumin. Blood fibrin dissolves more rapidly than egg-albumin in consequence of it being more finely divided to start with than the egg-albumin.

If we go back to the early history of pepsin, we find that until Prout, Tiedemann and Gmelin made the discovery that hydrochloric acid was present in the stomach, little was known of the action of pepsin although there was of gastric juice. Gastric juice was found to possess high solvent action on albumin, but pepsin isolated from it showed little action in the absence of hydrochloric acid. In the paper above referred to (*Jour. Chem. Soc.*, 1892, 934) I draw attention to a difference between the hydrolytic action of yeast and that of invertase prepared from it. Fernback (*Ann. Inst. Pasteur*, 9, 90) and O'Sullivan and Tompson (*Jour. Chem.*, 1890, 57) were unable to find any relation between the amount of invertase employed and its hydrolytic action until the "proper quantity of acid was used." Harden (*Jour. Inst. Brewing*, 1905, 11, 12) says that zymase—yeast juice—is capable of being divided by dialysis into a filtrate, and a residue neither of which, practically speaking, has any fermentative action on glucose; but if these are mixed the action on glucose is again comparable with that of the original yeast juice. He infers from this, if his results are confirmed, that it points to the necessity of a co-ferment. Yeast juice, when freshly prepared, is acid, as a rule, invertase is always alkaline, and in Harden's work there is no mention of the relative acidity of the residue and filtrate. It is most probable that the reason why the residue he obtained did not ferment the glucose was that the acidity was removed in the filtrate. Pepsin and invertase are enzymes which require acidity in order to obtain their maximum activity; may not zymase have a similar property?

DISCUSSION.

Mr. J. T. WOOD said that in experiments made by him on skins with pepsin, he had found the action so small that he had given up its use in favour of the more powerful trypsin. It seemed to him that hydrochloric acid alone at a sufficiently high temperature would produce the same effect as pepsin, while hydrochloric acid of the same strength as gastric juice had no action on albumin at 40° C., yet at higher temperatures it behaved like pepsin.

Mr. J. O'SULLIVAN said he could not say what action hydrochloric acid at high temperature would produce. As to the source of pepsin or its quality, he once had a sample which was no better than sand as far as proteolysis was concerned; on the other hand, he had a sample in his possession now which was as active as it was six years ago. He did not think there was anything definitely known as to the action of hydrochloric acid in combination with the albumin. If they could get the products of proteolysis to diffuse away they would most probably get a more rapid solution of the albumin.

Meeting held at Queen's Hotel, Leeds, on Monday, 17th, 1905.

PROF. SMITHILLS IN THE CHAIR.

MAGNALIUM AND OTHER LIGHT ALLOYS.

BY R. E. BARNETT, B.Sc.

The magnesium-aluminium alloy, known as magnalium, is interesting from its lightness, and further that amounts of heavier metals, such as nickel or copper, be added to it without raising its density above that of the fundamental metal, whilst at the same time considerably altering its mechanical properties.

The evolution of magnalium has been somewhat hazy. Wöhler in 1866 prepared two definite alloys Al_3Mg and $AlMg_2$, but these were of no practical use, both being brittle and easily oxidised. Since then many attempts have been made to obtain air-resisting magnesium alloys of good mechanical properties and in many of these the idea of adding very small amounts of active metals, but still keeping within the density of aluminium, has been more or less completely carried out. In a number of these alloys for which during the past few years a large number have been taken out, the magnesium has been at a range from 2 to about 30 per cent. of the aluminium. The general tendency has been for the amount of magnesium to be reduced, as the alloys containing more of this metal are mostly unworkably hard and brittle.

Alloys of these two metals containing more than 10 per cent. of magnesium have been thoroughly investigated from the scientific point of view, by Boudonard. He finds (this *J.*, 1901, 814, and 1902, 258) that the strength of these alloys diminishes as one recedes from the composition of the pure metals. Alloys in which the proportion of each constituent exceeds 15 per cent. are brittle, the maximum brittleness being reached with a 50 per cent. alloy, which can be crushed by the fingers. The strength curve has two maxima, corresponding to compositions represented by $AlMg$ and $AlMg_2$, both of which Boudonard succeeded in isolating.

At the present time, three magnalium alloys are in regular use, denoted by the letters X, Y, and Z. The first of these is for forging or for casting in which strength is a primary consideration. Casting is done at about 330° C., special care being taken to avoid oxidation. The second, Y, is ordinarily used for casting. To secure good results, oxidation must be carefully guarded against, the melted metal must not be agitated or overheated, and after casting the casting should be cooled as quickly as possible. The melting point is slightly above that of aluminium. The castings when properly made are clean and strong. The third alloy, Z, is used for rolling and drawing. Rolling is done between 300° and 350° C. Final annealing is necessary unless very hard sheet is required. Apart from the method pursued in rolling, it is stated that soft sheet can be made springy by heating to about 390° C. and slow cooling. Rapid quenching makes it soft. Similar considerations apply to drawing in rod, wire or tube. Frosting is done, as with aluminium itself, by alkaline liquors.

It will be noticed that except for its greater tendency to oxidation when hot, the treatment of magnalium by the foregoing processes is very similar to that required for aluminium. Magnalium has, however, two advantages at least over pure aluminium. Its tensile strength is decidedly higher. This is said to range from 10 tons in the case of ordinary castings (Y), up to 23 tons for Z, when rolled hard. The most conspicuous advantage is in its behaviour with cutting tools. As is painfully familiar to all who have had to use aluminium, such operations as filing, turning, drilling, and screwing are far from satisfactory with the

metal. It drags and tears and clogs the cutting. Very small cuts have to be taken at high speed, good lubrication. The case is very different with aluminium. It works cleanly in the lathe. When cut at a surface speed of 100 ft. per minute, without lubricant, long spiral shavings come off and the work left is free from any signs of dragging or tearing, also free from tool-marks, a circumstance which shows that the softness of the metal makes it flow on at the cutting edge. This idea is supported in a curious way in which the metal builds up on to the tool-edge when being turned or drilled without a coolant. I find that a cutting edge, whose angle is 65°, such as would do for steel, serves very well with aluminium. A less acute angle, such as is used for steel, is not so satisfactory. When turned in the manner described, a silvery-white surface is produced on all polishing operations seem superfluous.

In order to see if the presence of magnesium would make aluminium susceptible to corrosion, I made a comparative test by exposing sheets of magnalium to laboratory atmosphere for three weeks, side by side with sheets of aluminium, zinc, copper and iron; all the surfaces being in a precisely similar position. The magnalium showed no special signs of corrosion, and the laboratory atmosphere had decidedly less effect on the zinc, copper and brass.

As to chemical composition, careful qualitative analyses have been made of drillings from ingots of X and Y, and of a piece of soft sheet which is presumably Z. Detailed quantitative analyses have also been carried out, in the case of Y, which was done before the special difficulties of the analysis were fully realised, no great weight can be placed on the results, which are therefore approximate. The chief trouble was caused by the relatively small proportion of aluminium, which appears in each to exceed 94 per cent. In the qualitative analyses, the silky character of the aluminium hydroxide prevented amounts being taken and so rendered the detection of its constituents difficult. Moreover, it was found that in the re-precipitation, the aluminium hydroxide carried large quantities of other metals. For instance, after re-precipitation with ammonia in presence of ammonium chloride, the nickel (in alloy X) was present in apparently larger quantity in the aluminium oxide than in the united filtrates. It was noticed on boiling the liquid containing the precipitated oxide as usual to expel excess of ammonia, a marked change occurred. In consequence of these facts, in the qualitative work, and also in the quantitative analysis of X, the re-precipitated hydroxide was digested in pure sodium hydroxide solution in a platinum dish. Nearly all the aluminium was thereby dissolved after diluting and filtering, the residual precipitate, black-grey in colour, was dissolved in acid and then used for all metals beyond the "hydrogen sulphide" in the usual course.

In order to avoid this lengthy procedure, Mr. J. B. Murray suggested the preliminary treatment of the alloy with sodium hydroxide solution in order to remove the greater part of the aluminium before commencing the ordinary analytical separation. He applied this method to a complete analysis of the sample of soft sheet, namely Z, and found it very satisfactory. The solution of sodium aluminate was found to contain a trace of the tin, which was, however, easily precipitated as phosphuretted hydrogen after acidifying. The results of the analyses may be stated briefly as follows:—

Alloy X contains copper (1.76), magnesium (1.60), aluminium (1.16), and antimony and iron in smaller quantities. Alloy Y contains copper, magnesium, tin, lead, a small amount of iron and a doubtful trace of antimony. As far as I can judge, Y is intermediate in composition between X and Z, except as regards nickel. Alloy Z (sheet) contains tin (3.15), copper (0.21), magnesium (0.1), lead (0.72), and the usual amount of iron, about 1 per cent.

Traces of titanium were found, presumably derived from the bauxite. Indications of other rare metals were noted, but the difficulties in the way of taking large quantities of the samples for analysis prevented any

confirmatory work. Alloy X dissolved in *aqua regia* left an insoluble residue amounting to 0.38 per cent.

The most noteworthy result of the analytical work is that in no case was as much as 2 per cent. of magnesium found. The highest result was 1.86 per cent. in the soft sheet. This result was obtained by precipitating (twice) the magnesium as the double phosphate from an alkaline solution in which the aluminium was retained by the presence of alkali tartrates. But I have reason to believe that this result is too high. The alloy dissolves very vigorously even in diluted hydrochloric acid and considerable care is needed in this operation. It is little affected by nitric acid.

"Zisium" and "ziskon" are two light alloys prepared for use primarily in scientific instrument making. Zisium was first named zalum, but it was found that this name could not be registered. Both alloys are silver-white in colour and make good castings, in which form only they are supplied.

Zisium is the lighter, having a density of 2.95 as compared with 3.35 for ziskon. The latter is, however, much harder and stronger. The tensile strength of the metals (cast in sand) is stated to be nearly five and 11 tons per sq. in. respectively, according to tests made at the National Physical Laboratory. My experience of their working properties is confined to the making of turnings for the purpose of analysis. Zisium cuts like very soft brass, in short curly chips, using a tool as described for magnalium. Ziskon seems to have a texture resembling that of cast-steel, though, of course, much softer. It needs to be cut at a slower speed than zisium and gives long shavings.

Want of time has prevented my doing more than making a qualitative analysis of each of the two sample castings of these alloys which I have had. The results show, as might be expected from the specific gravity, that both are aluminium alloys. Zisium, like magnalium, appears to be essentially aluminium, modified by the presence of small amounts of other metals. I find in it zinc, tin, and copper with a trace of antimony, and a minute trace of bismuth and possibly thallium.

Ziskon has a different character. It is a zinc-aluminium alloy, containing perhaps one-fourth its weight of the former metal, as far as could be judged by a rough weighing of the zinc sulphide obtained in the qualitative analysis.

Zinc-aluminium alloys have been studied by J. W. Richards (abstract, this J., 1902, 121). He confirms the previous statements of Durand as to the remarkable mechanical properties of one containing one-third of its weight of zinc. It is very hard, resembling tool-steel, and its specific gravity is given as 3.8. On the other hand, alloys containing only one-sixth of zinc or less are soft enough for rolling or drawing. An alloy intermediate in composition, containing 25 per cent. of zinc, is said to give excellent castings, easily worked, and to be much used for scientific instrument-making. Its specific gravity is given as 3.4, thus closely agreeing with that of ziskon. These statements, I think, confirm the results of my examination of ziskon (given above).

A great many other aluminium alloys, containing such metals as zinc, copper, nickel, and tungsten, have been patented in recent years, and some are in actual commercial use.

The numerous aluminium bronzes do not come within the scope of this paper, as they are not light alloys, since aluminium is not their principal constituent.

In conclusion, I must express my indebtedness to Mr. J. B. Murray for a great deal of valuable assistance, and to Mr. J. Arthur Williams, of Hatton Garden, who has rendered indispensable help in the supply of specimens and information.

DISCUSSION.

Mr. C. P. FINN asked if Mr. Barnett had made experiments towards the examination of magnalium by micrographic methods of analysis. The results of such an examination of the structural changes produced in the alloy by chilling, &c., would be of great interest. What method should be used in soldering magnalium? How did the co-efficient of expansion of the alloy compare with that of aluminium?

Mr. J. W. COBB said the alloy appeared to be soft, and so would easily scratch and flow, and be difficult to polish. Decreasing hardness made polishing increasingly difficult, as for example in the case of lead. This would, no doubt, interfere with the obtaining of polished surfaces suitable for photo-micrographic study. Were the aluminium laboratory punts used to prevent corrosion of apparatus, &c., analogous in composition to magnalium? He could appreciate the difficulties of securing good separations by double precipitation, as, in analysing magnesite, he had found three or four precipitations necessary to secure satisfactory results. Since small quantities of molybdenum and tungsten converted steel into a high speed cutting steel, with special properties, the presence of titanium even in small quantity might produce its own effect in magnalium. For this reason, he thought it should not be concluded, that because the titanium was probably introduced through the bauxite, from which aluminium was extracted, it would not have some effect on the properties of the alloy.

Mr. T. FAIRLEY suggested that there was a possibility of the amount of magnesium in the alloy diminishing in the working or casting. If 2 per cent. were originally present, the final percentage might be much lower owing to oxidation by the atmosphere during heating. He had given students analyses of aluminium paints for exercises in examinations, and in certain cases the results showed the presence of about 3 per cent. of tin. He supposed

magnalium like aluminium was affected by caustic alkalis.

Mr. F. W. BRANSON said, that while at King's College came across an aluminium alloy which contained a little silver.

Mr. R. E. BARNETT said he had done nothing to test suitability of magnalium for photo-micrographic study and had seen nothing on this point in any description of the alloy. He thought Mr. Cobb's view would be correct. In turning the metal, the remarkably even surfaces suggested that it flowed in front of the cutting tool. To get a surface for metallography, he thought something like casting to glass, and then breaking away the latter, might be resorted to. The alloy would have to be soldered like aluminium; no flux should be used, but a silver solder of aluminium with some other metals. Scrubbing under the molten solder with the bit or even with a brush would be necessary to remove oxide. Other alloys of aluminium and magnesium, such as magnalium, are used for flash light purposes, probably contained magnesium. The analytical results were curious, showing remarkably low percentages of magnesium, and were puzzling discrepancies between these results and published statements. If the amount of magnalium originally put into the alloy was the published percentage, this discrepancy might be explained by Mr. Fairley's suggestion, that some magnesium was lost through oxidation in the heating and preparation of the alloy.

or Evaporating Liquids; Apparatus for —. Grace, Assignor to H. R. Worthington, New York. U. S. Pat. 793,129, June 27, 1905.

ig. Pat. 7468 of 1905; this J., 1905, 792.—T. F. B.

ing Apparatus. A. Hinze, Rositz, Germany. U. S. Pat., 793,133, June 27, 1905.

AM-JACKETED tank is divided into compartments titions, which are perforated alternately above and A shaft, mounted horizontally in the tank, through all the compartments and has spirally- radial arms and perforated scoops mounted t. The material to be treated and the lixiviating are caused to pass through the tank in opposite ons.—W. H. C.

ing Liquids; Apparatus for —. S. H. Johnson, gnor to S. H. Johnson and Co., Ltd., London. U. S. Pat. 793,725, July 4, 1905.

ng. Pat. 10,753 of 1904; this J., 1904, 757.—T. F. B.

ing Apparatus —. E. E. Morlan, Kansas City, Kans. U. S. Pat. 793,732, July 4, 1905.

AM generating retort A, enclosed in composite walls ver, B and 13, has a gauge pipe C and a steam outlet is shown, provided with a deflector E and communi- with the inclined pipe F. The latter has depressions

G, G, formed on its lower side, and condensers H, H, H, communicating by the pipes J, J, and arranged as shown in the figure; it is also provided with a trap K.—W. H. C.

FRENCH PATENTS.

Drying Machines with Intermittent Discharge Openings. G. ter Meer. Fr. Pat. 351,143, Jan. 26, 1905.

THE material is fed into the machine through a centrally placed conduit in the shaft, and the drying is effected by centrifugal force, which throws the water through the screens. Slides or the like are provided for cutting off the supply when it is desired to empty the machine. The discharge of the dried material may be effected by the centrifugal force itself, which throws out the material when the machine is opened. Two or three methods of arranging the filtering material or gauze are described. —W. H. C.

Furnace; Industrial Regenerative —. E. Lionne. Fr. Pat. 351,083, Jan. 28, 1905.

THE muffle or crucible heating chamber is surrounded by two concentric annular chambers, with metallic walls. The air necessary for combustion, passes first through the outer and then through the inner chamber. It is claimed, that the use of metal for the construction of the heating chambers facilitates the passage of heat and enables the furnace to be easily set up or taken to pieces. The primary and secondary air may be led through separate regenerative chambers.—W. H. C.

II.—FUEL, GAS, AND LIGHT.

"Cyanogen Mud." A. Hand. Z. angew. Chem., 1905, 18, 1098—1106.

THE author has investigated the composition, &c., of the "cyanogen mud" obtained in the Bueb process of separating hydrocyanic acid from the gaseous products of destructive distillation, especially of coal (this J., 1900, 999; 1903, 204, 356). His results differ considerably from those obtained by Feld (this J., 1904, 316). If the conditions prescribed by Bueb, especially with regard to the concentration of the ferrous sulphate solution, be maintained, the "cyanogen mud" is obtained as a dark brown mass containing:—(1) in solution: ammonium ferrocyanide, ammonium sulphate, ammonium carbonate or bicarbonate, small quantities of ammonium sulphide, ammonium thiosulphate, and, on the average, about 0.13 per cent. of ammonium thiocyanate; and (2) in the insoluble portion: an insoluble ammonium-iron-cyanogen compound, which is the chief constituent, undecomposed ferrous sulphide, tar, oily substances, and mechanical impurities such as sand, and ferric oxide from the iron

connections, &c., of the gas plant. The amount of cyanogen, expressed as Prussian blue, $\text{Fe}_7(\text{CN})_{18}$ ranges in general from 8 to 15 per cent. The insoluble iron-ammonium-cyanogen compound was found to be a double compound of ferrous cyanide and ammonium cyanide, $2\text{NH}_4(\text{CN}) \cdot \text{Fe}(\text{CN})_2$; it is usually accompanied by moderate quantities of soluble ammonium ferrocyanide. Feld's proposal to use weaker solutions of ferrous sulphate is considered to be unsatisfactory, results obtained in practice having shown it to be more advantageous to fix the cyanogen in the form of the insoluble iron-ammonium-cyanogen compound than as soluble ammonium ferrocyanide. Feld's statement that the recovery of the ammonia in "cyanogen mud" is too complicated a process to be undertaken in the gas-works, is also controverted, and the author shows that by merely boiling the mud or by treating it with acid, the insoluble compound mentioned above, is converted into the white insoluble compound $(\text{NH}_4)_2\text{Fe}_2(\text{CN})_6$, with separation of ammonia; after this treatment, three-fourths of the total ammonia is present in the soluble form. The reaction proceeds according to the equation:—

and if the mud does not contain sufficient undecomposed ferrous sulphide for the purpose, a suitable addition of ferrous hydroxide or sulphide must be made. In presence of sufficient ferrous hydroxide or sulphide, the soluble ammonium ferrocyanide is also converted into the white insoluble compound.

The difference between the results obtained by Feld and by the author in the examination of the "cyanogen mud," is attributed to the different methods used for the determination of the soluble ferrocyanide and ammonia.

According to Feld the "cyanogen mud" after being diluted with cold water will not filter clear, and he therefore recommends an addition of magnesium chloride solution. The author finds, however, that by diluting with a smaller quantity of water, e.g., 50 grms. of mud with water sufficient to make a total volume of 260 c.c., a perfectly clear filtrate can be obtained. In the author's hands, Feld's method (this J., 1903, 1068) gave varying results with one and the same sample of mud, owing probably to decomposition of some of the constituents of the mud caused by the excessive dilution with water, and favoured by the presence of the weakly basic magnesium chloride.—A. S.

ENGLISH PATENTS.

Fuel; Manufacture of Peat —, and *Apparatus therefor*.
L. Whittaker and C. Whittaker and Co. (1900), Ltd., Accrington. Eng. Pat. 13,822, June 18, 1904.

THIS patent relates to a process and apparatus for making peat fuel blocks. The peat is dried in a centrifugal machine, provided with a removable scraper for removing the peat from the sides, and causing it to fall through a door at the bottom on to an edge-runner mill. After being ground, the peat is kneaded in a steam-jacketed vessel provided with a worm of diminishing pitch, whereby the peat is expressed through a nozzle in a long column, which is then cut off into finished blocks. The edge-runner mill is arranged so that one roller runs over a dead or smooth part of the pan, and the other over grids, the bars of which have sloping faces, and together with suitably arranged guide plates, this second roller exerts a scissors-like action on the peat. A plunger pug-mill may be used in place of the tapered kneading machine, the pug-mill being provided with a valve to admit air to the compression chamber, and thus prevent the plunger tending to suck back the column of peat, on the return stroke.

—W. C. H.

Fuel. H. B. Bayles, Brooklyn, U.S.A. Eng. Pat. 14,947, July 4, 1904. Under Int. Conv., July 2, 1903.

THE claim is for a fuel composed of asbestos or other fibrous material saturated with glycerin which is said to burn with a hot smokeless flame.—W. H. C.

Briquettes; Process for the Manufacture of Coke
L. L. D. Zuiderhoek, Amsterdam. Eng. Pat. 13,800, Aug. 17, 1904.

100 PARTS of powdered and sifted coke are mixed with say 3 to 10 parts of lime, and 1 to 3 of Portland cement, and 10 to 20 per cent. of water added, pressed in the form of steam or spray. The mass is allowed to set and then pressed into briquettes in suitable moulds.—W. C.

Blast Furnace Gases; Method and Apparatus for Rendering Iron — Available for Working Gas Engines. B. H. Thwaite, London. Eng. Pat. 13,787, June 30, 1904.

THE invention relates to improvements in methods and apparatus for washing blast furnace gases described in Eng. Pat. 8670 of 1894 (this J., 1895, 663), and 23,597 of 1896 (this J., 1896, 724, and 1897, and 4225 of 1901).

The claims are for the arrangement of the box work in series, for the addition of tar or oil to the water washers and to that supplied to the fan, and for the construction of a sawdust filter provided with a rotating agitator to shake up the filtering medium.—W. I.

Gas Producers; Impts. in —. G. Hatton, Bristol Staffs. Eng. Pat. 18,214, Aug. 23, 1904.

FOR mixing atmospheric air with steam or water and supplying the same to the gas producer, use is made of a vaporising chamber containing a water spray heated internally by waste heat from a chimney vapour from this chamber passes into a mixing chamber together with a supply of atmospheric air drawn in by a blower, which latter also draws or forces the hot air from the chimney into the vaporising chamber and delivers the mixture to the gas producer.—C. S.

Carburetted Air and other Gases; Automatic Apparatus for —. E. Bouchaud-Pracig, Angoulême, France. Eng. Pat. 6158, March 23, 1905. Under Int. Conv., March 31, 1904.

THE air or gas to be carburetted is forced through a meter, connected by a flexible tube with a vaporising vessel charged with the carburetting liquid, and a reservoir with which it communicates by one or more flexible tubes. The supply of carburetting liquid is controlled by the gas meter, the movable vessel being mounted on a screw nut, working on a spindle actuated by the mechanism of the meter, so that as the screw rotates, the vessel moves downward. The nut is provided and fitted with a spring hinge, so that on reaching the bottom of its travel it can be returned, with the attached vessel, to the top of the spindle.—C. S.

Incandescence Bodies; Manufacture of Electric
The Electric Equipment and Securities, Ltd., London, and C. Ruzicka, Willesden, Middlesex. Eng. Pat. 16,425, July 25, 1904.

THE material consists of a mixture of one or more non-conductors of high melting point (e.g., iridium, or an iridium alloy), one or more refractory non-conductors (e.g., zirconium oxide), which are normally non-conducting, but increase in conductivity as the temperature rises, and one or more special earths, such as gadolinia, cerite, or the oxides of rare earth metals, e.g., ceria.—C. S.

Filaments for Incandescing Electric Lamps; Manufacture of —. J. R. Crawford, London. Eng. Pat. 14,933, June 11, 1904.

ONE or more carbides of the earth metals are mixed with either a metal of high melting point, such as molybdenum or boron, or a mineral of high melting point, such as silica, or like silicates of the earth metals, feldspar, quartz, or magnesium oxide, in the ratio of about 3 parts of the former to 2 of the latter. When a refractory mineral is used, the metal in it is reduced by causing the filament to glow in an atmosphere of a reducing gas.—W. I.

ascend Electric Lamps; Manufacture of Filaments — A. Just and F. Hanaman, Vienna, Eng. Pat. 23,899, Nov. 4, 1904.

Pat. 347,661 of 1904; this J., 1905, 431.—T. F. B.

UNITED STATES PATENTS.

Process and Method of Making same. H. E. Mat-b, for to W. P. Wag, Los Angeles, Cal. U.S. Pat. 793,795, July 4, 1905.

EIGHT parts of fine coal are intimately mixed with one part of lime or gypsum, and the whole moistened with one part of water in which 1 part of gelatin and 1 part of potassium bichromate have been dissolved. The mixture is thoroughly incorporated, and afterwards pressed into briquettes and dried.—W. H. C.

Gas; Furnace for Burning — W. L. Harder, Birmingham, Ala. U.S. Pat. 793,070, June 27, 1905.

The furnace, which is for burning producer gas under a boiler, is provided with an ignition chamber which enters into the outer end of the combustion chamber, which is surrounded by walls of refractory material, the latter not being exposed to the chilling influence of the boiler. The gas and air are preheated by passing through conduits disposed within the chambers, and then enter the ignition chamber, means being provided for regulating the supply of gas. Here the preheated mixture of gas and air is ignited before entering the combustion chamber. The chambers and conduits have a refractory flooring and are so constructed that the gas admitted flows in a substantially straight course.—R. L.

Producer. W. Viggers and R. F. Ball, Durango, Mexico. U.S. Pat. 793,554, June 27, 1905.

The producer consists of a cylindrical shell, closed at top and bottom. A ring is fixed to the inside of the central portion and a crucible is suspended from it by means of an outwardly projecting flange on the top. The crucible, in which the gas is generated, is surrounded by a water-jacket and provided with a cover on its bottom. A cylindrical magazine, open at the top and closed at the bottom by a removable cover, is connected from the top of the outer shell over the top of the crucible and acts as a feeding hopper. The pressure of water to the water-jacket can be adjusted by a valve arrangement. The steam raised in the jacket is conveyed into a blow-pipe and is discharged, or with air drawn in, into the crucible through a bottom grating. To keep the fuel in the desired state of incandescence, the air chamber surrounding the crucible may be connected with a fan blower. The generated gas is discharged through a service pipe at the bottom of the producer.—R. L.

Producer. A. B. Duff, Pittsburg, Pa. U.S. Pat. Reissue, 12,367, July 4, 1905.

The invention relates to a special form of gas-producer, which, by means of one or more louvred cones, superimposed on the gratings in the lower part of the producer, permits of the emission of air can be closely controlled. The air between the cones and the gratings are so proportioned, that a sufficient quantity of air is admitted to the upper portion of the fuel in the producer to produce incandescence, while the lower mass of fuel is kept at the desired temperature for the proper working of the gas-producing process.—J. B. C. K.

Generator. W. Necken, Mülheim-on-Rhine, Germany. U.S. Pat. 794,037, July 4, 1905.

The form of gas-producer covered by this patent, has an air chamber supplied with water arranged around the combustion chamber at a part intermediate between the top and bottom. The steam produced in this chamber is used in the gas-producing process. Claim is also made for an intermediate opening for gas-discharge.—J. B. C. K.

Gas Generating Apparatus. L. Guenot, Paris, U.S. Pat. 794,498, July 11, 1905.

SEE Eng. Pat. 11,105 of 1904; this J., 1905, 79.—T. F. B.

Gas Purifier. E. A. Uehling, Passaic, N.J. U.S. Pat. 793,110, June 27, 1905.

THE apparatus consists of an upright cylindrical shell, with a central shaft extending longitudinally through it and provided with a helical flange. The gas is forced through the purifier in an upward direction, and at a high velocity by an exhausting fan. By means of the spiral flange, a rotary motion is imparted to the gas, which is washed by water continually running down the inner surface of the shell from a tank surrounding the top of the purifier, and directly connected with it throughout its periphery, by means of an overflow. The washing liquor is collected at the bottom of the purifier and discharged through a water-sealed overflow.—R. L.

Gases; Apparatus for Purifying Blast-Furnace Gases. — W. Schwarz, Dortmund, Germany. U.S. Pat. 793,544, June 27, 1905.

SEE Fr. Pat. 350,592 of 1905; this J., 1905, 794.—T. F. B.

Gases; Means for Removing Dust from — J. Shields, Willesden Green, Middlesex. U.S. Pat. 793,745, July 4, 1905.

A CONICAL chamber *a*, is continuously fed with "granular

material" from the hopper *h*, so that a mound *b*, is formed which has a conical top as shown. The gas, which is to be freed from dust, enters by the conduit *c* into the centre of the mass and passes upwards through the "granular material," and away by the pipe *l*, leaving the dust behind. The dust-laden material is removed from the bottom of the chamber by the screw conveyor *d*, and after being cleansed, is raised through the pipe *g* and delivered again into the hopper.—W. H. C.

Gas; Process of Purifying — A. W. Fischer, Assignor to Schutte and Koerting Co., Philadelphia, Pa. U.S. Pat. 794,000, July 4, 1905.

A METHOD is claimed for separating gases, vapours or solid particles from any gaseous medium or mixture, by means of a liquid spray or mist. The liquid to be used for this purpose is heated in a separate vessel to a point considerably above its boiling point, under pressure, and the superheated liquid is then delivered by any suitable device, into the chamber containing the gaseous mixture. A rapid diffusion of the purifying liquid is thus obtained in the form of spray or mist, and the sub-

stances which are to be removed from the gas, are carried down and precipitated with this mist, as it condenses on the floor of the chamber.—J. B. C. K.

Gas Purifying Apparatus; Centrifugal —. E. Theison, Baden-Baden, Germany. U.S. Pat. 794,201, July 11, 1905.

SEE Eng. Pat. 8761 of 1903; this J., 1904, 434.—T. F. B.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, PETROLEUM, AND MINERAL WAXES.

[Petroleum] *Illuminating Oils; Relation of Flashing Points to the Boiling Points of* —. P. Dvorkovitz. Pet. Rev., 1905, 13, 7—8; 24—25.

THE experiments made, are considered to confirm the author's opinion that the distillation test is the true criterion of the safety of petroleum oils, since it reveals the actual proportions of light oils present. The flashing points of Roumanian, Galician and "Royal Daylight" burning oils are approximately the same (26.0—27.5° C.), and though they all contain about 12 per cent. of fractions flashing below 0° C., the two latter oils contain 54.27 per cent. and 50.75 per cent. of fractions flashing at 60° C., whilst

the Roumanian oil contains only 37.96 per cent. of fractions. The following table gives the flashing points of the principal fractions of these and other oils:—

Flashing Points.

Fraction boiling at	170° C.	270° C.	300° C.	above 300° C.
Royal daylight (sp. gr. 0.804) ...	15	—	87	1
Russian oil (sp. gr. 0.825)	16	—	120	1
Texas oil (sp. gr. 0.819)	17	99	(no higher fractions)	1
Galician oil (sp. gr. 0.812)	20½	—	124	1
Amer. water-white (sp. gr. 0.7954) ..	22	—	125	1
Roumanian oil (sp. gr. 0.811) ...	24	—	99	1

The difference between the two American oils is mainly due to the low-flash oil containing about 12 per cent. of light fractions and 16 per cent. of fractions above 300° C., the figures for the other oil being 1½ per cent. and per cent. respectively. Again, while the several fractions have similar sp. grs. in each case, the flashing points are considerably (16—30°), thus indicating a great dissimilarity in the constituent hydrocarbons. In the case of Roumanian oil, the sp. gr. of the fractions above 210° C. shows a remarkable increase, the range between 210° point and 300° C., being 0.821—0.873, the latter of which exceeds the figure for the corresponding fraction of Russian oil (0.8645). The Texas oil contains lighter fractions similar to those in Roumanian oil, whilst the sp. gr. of the middle fractions is higher than that of Russian oil, and there are no fractions above 270° C. The author considers that safe oils of good candle power would be ensured by the adoption of a standard for illuminating oils of not more than 10 per cent. of fractions boiling below 150° C., these being counterbalanced by a similar quantity of fractions boiling above 300° C.—C. S.

ENGLISH PATENT.

Peat, Turf, Wood and other similar Materials; Apparatus for Treating [Carbonising] —. T. R. Hargreaves, Manchester. Eng. Pat. 16,543, July 27, 1904.

per parts of the retorts A are made of cast iron, and provided with balanced charging cones C, and with gas-delivery pipes F G extending into the hydraulic L. The upper portions A are set in a heating furnace D, arranged above a furnace E, while the lower parts B, are of brickwork or of iron set in brickwork, curved as shown in the fig., and provided with closing doors K and with pipes P for injecting steam. Distillation takes place in the upper portion A, and the parts B serve as cooling chambers for the residual L.—W. H. C.

paratus consists of a casing containing a fire-box, which is a heater that prevents the flame from directly upon a pair of retorts arranged side by side. Above the retorts communicates with the fire-box, a discharge pipe leading out of the casing.—E. S.

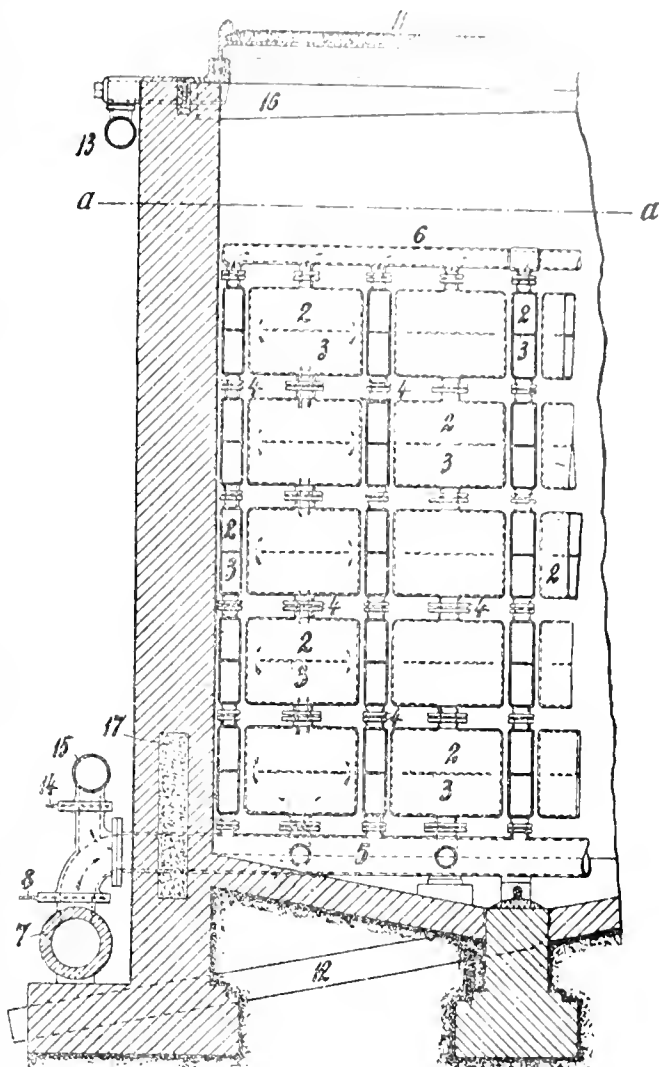

FRENCH PATENTS.

Products [from Coal]; Recovery of — in the Manufacture of Coke. Dr. C. Otto and Co., G.m.b.H. Fr. Pat. 465, Dec. 30, 1904.

rocess for the recovery of the by-products in the distillation of coal consists in conveying all the products of distillation, including the ammoniacal liquor, to a point where the temperature of the gas has been lowered to 3° C., or below the boiling point of water, and then giving their course at that point. The reflux pipe has a lined position. The hot gases cause renewed distillation of the light hydrocarbon and ammonia from condensed tar, and condensation takes place according to the temperature of the returning gases. The quantity of oil and tar required for the extraction of ammonia from the outflowing gas is very small, and a concentrated ammoniacal liquor can be obtained. —R. L.

Distilling Wood, Peat, and other Similar Substances; Process and Furnace for — C. J. R. Müller. Fr. Pat. 351,209, Feb. 1, 1905. Under Int. Conv., Feb. 6, 1905.

urnace consists of a rectangular casing, the bottom of which slopes downwards towards the centre (to enable liquid residues to be easily collected), and provided with a removable top; the casing is divided into vertical compartments by a number of thin hollow elements 2, 2, vertically above one another as shown in the figure, provided with baffle plates 3, 3; each one is connected to the one above it by flanged tubes 4, 4; these are traversed by gas or other heating media, introduced into the pipe 7 to 5, where they are distributed in a series of chambers. The wood, peat, &c., is introduced into the vertical compartments of the furnace skeleton made of iron wire or perforated sheet iron. Carbonisation is complete, cold water or other cooling medium is caused to traverse the heating system, avoiding the direct quenching with water usually

resorted to. The gases and other products of distillation are drawn off by the pipe 13.—T. F. B.

By-products, especially Ammonia, from Gases obtained by Dry Distillation, or by the Gasification of Combustibles; Simplified Process for the Recovery of — H. Koppers. Fr. Pat. 351,268, Feb. 4, 1905.

THE crude gas obtained by distillation, is cooled to the temperature most suitable for the separation of the tar, and the water separated at the same time, is then re-vaporised and reintroduced into the gas, which is afterwards heated, and treated in a bath of sulphuric acid, the strength of which is kept constant, and from which the salt which is separated is continually removed. The liquor remaining after the re-vaporising process, is treated in a column still, and the vapours pass directly to the acid bath. The apparatus designed for carrying out the process, comprises, amongst other things, three coolers, of which the first serves also to heat the gas after removal of tar, the second for the re-vaporising of the water separated on cooling the crude gas, the necessary heat being derived from the crude gas itself. There is also an apparatus provided, with finely perforated sheet-iron plates, through which the gas passes in order to separate tar in suspension.—W. C. H.

IV.—COLOURING MATTERS AND DYE STUFFS.

Aromatic Azo Compounds and Aromatic Amines: Reaction between — entirely distinct from that of the Induline Malt. A. Weinschenk. Z. Farben- u. Text.-Ind., 1905, 4, 337—339.

EQUIMOLECULAR proportions of *a*-naphthylamine and azobenzene are heated together to 70°—120° C. in solution in excess of 70—80 per cent. sulphuric acid. The products are (1) benzidine, to the extent of almost half the weight of the azobenzene used, and (2) a mixture of bases, the sulphates of which are readily soluble in dilute sulphuric acid. This mixture of bases is also readily soluble in dilute hydrochloric acid. It can be acetylated in the usual manner, and then loses the power of forming salts. It is diazotisable, reacting with about half its weight of sodium nitrite, in hydrochloric acid solution, to form a diazo-solution of deep brown colour. This solution combines with amines and phenols to form direct azo dyestuffs. It can be combined, for instance, to half the possible extent with a naphthionic acid or γ -acid salt in presence of sodium acetate, or in acetic acid solution, to form insoluble products, which react with an alkaline H-acid salt solution to form unsymmetrically combined azo dyestuffs. By treating the original base with only half the quantity of sodium nitrite with which it is capable of reacting, an insoluble diazo compound is formed, which is converted into the soluble compound by more nitrite. The azobenzene in the above reaction may be replaced by other azo compounds, including azo dyestuffs, and the *a*-naphthylamine by other aromatic amines. *o*-Azo-toluene does not yield noticeable amounts of tolidine when treated with *a*-naphthylamine under the above conditions. —E. F.

ENGLISH PATENTS.

Dyestuffs: Manufacture of Anthracene —, and their Application in Dyeing and Printing. H. E. Newton, London. From Farbenfabr. vorm. F. Bayer and Co., Elberfeld, Germany. Eng. Pat. 20,527, Sept 23, 1904. SEE Fr. Pat. 346,398 of 1904; this J., 1905, 128.—T. F. B.

Colouring Matters [Azo Dyestuffs]: Manufacture of Azo —. J. Y. Johnson, London. From the Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. Eng. Pat. 11,205, May 29, 1905.

DIAZO-COMPOUNDS of the benzene and naphthalene series are combined with the 1,3-dihydroxyquinolines described in Ger. Pat. 117,167. The colour of the products ranges from lemon-yellow to reddish-brown, and they are specially suitable for the manufacture of lakes. The dyes obtained from non-sulphonated and non-carboxylated amines are insoluble in water, whilst those obtained from aminosulphonic or aminocarboxylic acids can be converted into sparingly soluble or insoluble lakes. For example, 93 parts of aniline are diazotised in the usual manner and the solution poured at the ordinary temperature into a solution of 205 parts of the disodium salt of 1,3-dihydroxyquinoline in 3000 parts of water and excess of sodium carbonate. The product is yellow.—E. F.

UNITED STATES PATENTS.

Dyestuff: Anthracene —, and Process of Making same. O. Eddy, Mannheim and H. Wolff, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 793,558, June 27, 1905.

SEE Addition of Jan. 6, 1905, to Fr. Pat. 349,531 of 1904; following these.—T. F. B.

Diazo Compounds [of the Naphthalene Series]: Process of Making —. T. Sandmeyer, Assignor to Anilino Colour and Extract Works, formerly J. R. Geigy, Basle, Switzerland. U.S. Pat. 793,743, July 4, 1905.

SEE Eng. Pat. 10,235 of 1904; this J., 1905, 433.—T.F.B.

Dyestuff: Orange-Red Acridine —. O. Sohst, Assignor to Farbwerke vorm. Meister, Lucius and Brüel, Hoechst on the Main, Germany. U.S. Pat. 794,571, July 4, 1905.

LEUCO-ACRIDINE Yellow is alkylated with alcohol hydrochloric acid, and the product is heated to a temperature with formaldehyde and concentrated sulphuric acid. The dyestuff thus obtained is soluble in water to an orange-yellow solution, dyeing orange shades on cotton treated with tannin, and on leather. The dyestuff dissolves in sulphuric acid to a yellowish solution with green fluorescence, which turns orange and the on addition of water. It is soluble with difficulty in alcohol, and insoluble in ether, petroleum spirit ("light") and benzene.—T. F. B.

Dyestuff: New Azo —. A. Thauss, Elberfeld, Germany. Assignor to Farbenfabr. of Elberfeld Co., New York. U.S. Pat. 794,568, July 11, 1905.

THE dyestuffs obtained by combining diazo compounds (e.g., that of *o*-toluidine) with *m*-aminobenzenylthio aminonaphthol-7-sulphonic acid are brownish or reddish-red to bluish-red shades; they are capable, when the fibre of being diazotised and combined with β -naphthol, of dyeing deeper shades being thus obtained, and are fast to washing.—T. F. B.

FRENCH PATENTS.

Dyestuff [Sulphide Dyestuff] Dyeing Unmordanted Cotton Manufacture of a Black —. H. R. Vidal and J. Junius. Fr. Pat. 349,873, April 21, 1904.

THE dyestuff obtained by the action of limited quantities of sodium sulphide on hydroxyazobenzene, nitrosophenol or *p*-naphthol, which dyes unmordanted cotton in wine-red shades, is treated either with sodium hydrosulphide or with sodium sulphide and sulphur. The product is directly soluble in water and dyes unmordanted cotton in black shades, very fast to alkalis, and requires no oxidising agent for their development. It may be used for printing. Its solutions possess the characteristic property that they are not precipitated by the air. For example, 15 kilos. of the crude dyestuff obtained from hydroxyazobenzene and limited quantities of sodium sulphide, 12 kilos. of sodium hydroxide solution of 40° B, and 5.5 kilos. of sulphur are heated to 250° C. with stirring.—E. F.

Dyestuffs capable of being Chromed on the Fibre. Reduction of Azo —. Soc. pour l'Ind. Chim. Appl. Fr. Pat. 351,125, Jan. 4, 1905. Under Int. Cl. Dec. 27, 1904.

SULPHONIC acids of 1-amino-2-hydroxynaphthalene are converted by treatment of their basic salts with acidifying agents such as acid anhydrides or acid chlorides into 1-amino-2-acidoxynaphthalene sulphonic acids. The latter are readily converted in the usual manner, in presence of ice and mineral acid, into the corresponding azo-compounds, and are then combined, either as such or after separating the acidyl group by allowing to stand or by heating gently, with amines or phenols to form azo dyestuffs. For example, 23.9 kilos. of 1,2,4-trihydroxynaphtholsulphonic acid are dissolved in 200 litres of water and 29 kilos. of sodium hydroxide solution of 30° B. Acetylation is then effected by agitation of this solution with 11 kilos. of acetic anhydride at 0°—10° C. Seven kilos. of sodium nitrite are added to the neutral or weakly alkaline solution, which is then acidified by quickly adding 30 kilos. of commercial hydrochloric acid, the temperature of the liquid being kept at 0°—10° C. The product of the reaction, from which yellow crystals of the azo-compound separate, is then poured into a solution of 18 kilos. of β -naphtholate of sodium in an excess of sodium carbonate solution. A red acetylated dyestuff is formed which is converted into a greenish-blue dyestuff on heating to 30°—40° C. The latter dyes wool from an acid bath in violet shades which change to deep blue by chroming on the fibre. The same final product is obtained by allowing the diazo-compound to stand

acetylated, and then combining with β -naphthol. 4-aminonaphtholsulphonic acid may be replaced by sulphonic acids of 1-amino-2-naphthol, for example by 1,2,8-aminonaphtholsulphonic acid or aminonaphtholdisulphonic acid.—E. F.

Uses of the Anthracene Series; Production of New Dyes and —, and their Applications in Dyeing and Printing. Badische Anilin und Soda Fabrik. First Addition, dated Jan. 6, 1905, to Fr. Pat. 349,531, Dec. 21, 1904. Under Int. Conv., Aug. 20, 1904.

According to the original patent (this J., 1905, 726) new dyes, termed benzanthrones, are prepared by condensing glycerol with anthraquinone derivatives, their sulphonic acids, and their reduction products, that is, anthrol, oxanthranol, &c. According to the present invention hydroxyanthraquinones and their reduction products, such as alizarin and quinizarin, may also be condensed with glycerol, for instance in sulphuric acid solution. It is best, in starting from an unreduced anthraquinone, to add a reducing agent, such as sulphate, aniline sulphate, zinc or tin, to the melt. The product obtained from alizarin dyes on mordants.

Action of Human — on Bleached Cotton. E. Schuch. J. Soc. Dyers and Col., 1905, 21, 189—190.

A piece of bleached cotton, saturated with saliva, and then taken up considerably more dyestuff than when dyed with a direct cotton dyestuff than untreated cotton; after 20 minutes' treatment, the cotton taken up was roughly double that taken up by untreated cotton. This is not due to mucus, or to the salts contained in the saliva, but probably to the enzyme ptyaline, since saliva loses the characteristic property after boiling. Of other enzymes, diastase is also found to have some action, but even under the most favourable conditions it was very slight indeed. The action of saliva may explain some of the faults in goods with which dyers have frequently to contend.

Silk; Process of Making Artificial —. G. D. Lacroix. Fr. Pat. 351,265, Feb. 4, 1905. Under Int. Conv., Feb. 6, 1904.

In place of using nitro-cotton containing 25–30 per cent. of moisture for the preparation of collodion, a nitro-cotton containing 35–45 per cent. is employed; after nitration and washing, no drying is necessary, the material being gently pressed. Such a material is stated to be very economical to use, inasmuch as it requires less ether for its solution than nitro-cotton containing less moisture. A solvent consisting of equal parts of ether and alcohol is preferable to 2 parts of alcohol as generally used.

Colours giving a "Shot" Silk Effect; Process of Making —. C. Ludewig. Fr. Pat. 351,274, Feb. 4, 1905.

MINERAL colouring matters are mixed with a hot solution of glue or gelatin to a thick paste, which is dried, ground, and mixed with bronze powder, and then applied to freshly-printed surfaces. By subsequent brushing, a "shot-silk" effect is stated to be produced.—A. S.

VI.—COLOURING WOOD, PAPER, LEATHER, &c.

Rattan Canes [for Chairs]; Bleaching of —. Jenckel. *Färber-Zeit.* 1905, 16, 193–195.

RATTAN canes, imported from Singapore, have generally been freed from the layer of bast fibres before shipment. One species has a distinctly resinous surface, whilst another is quite smooth; both kinds are covered with a silicious

scale which must be removed before bleaching, canes are sorted according to thickness, flexibility colour; the soft canes are rejected. The sorted canes are scoured with sand and then immersed, in a bath of 5 tons, in a 1–2 per cent. solution of hydrofluoric acid for two or three hours. They are then removed, washed, re-arranged and immersed for a further 1 of two hours. The acidified canes are then neutralised by immersion over-night in a solution of sodium carbonate. The bleaching of these canes can only be effected satisfactorily by means of an alkaline hypochlorite bath. It is prepared by the addition of excess of sodium carbonate to a solution of calcium hypochlorite; the hypochlorite prepared electrolytically from brine gives unsatisfactory greenish shades. The strength of the bath should be equivalent to a N/10–N/7 solution of available chlorine with an alkalinity equal to a N/10 solution. The time of bleaching depends very much on the temperature; at 15° C. is an average duration. With lignified tissues such as these, there is a very great danger of spoiling the colour by over-bleaching. The accumulation of bicarbonate is prevented by the occasional addition of slaked lime. After immersion for three hours, the canes are removed and the available chlorine, alkalinity and temperature of the bath are determined; the duration of further treatment (3–5 hours) and the necessary addition to the bath are then calculated from the results. After the second immersion, the canes are rinsed and hung to dry; if they are dull in colour, they are improved by completing the drying at 40° C., if reddish, they are treated over-night with sulphur dioxide whilst still half dry. In any case, they receive a further treatment with sulphur dioxide after drying; 10 kilos. of sulphur dioxide are sufficient for five tons of cane. The darker coloured canes are then sorted out, but a second bleaching is useless for improving their colour. The subsequent treatments, such as polishing, slicing, etc., are mechanical and improve the lustre and flexibility. Only the outside of the canes is used for chair seats; the insides or "peddy" are unaffected by the bleaching process.—J. F. B.

ENGLISH PATENTS.

Leather; Process of Dyeing —. C. D. Abel, London. From Act.-Ges. f. Anilinfabr., Berlin. Eng. Pat. 18,096, Aug. 20, 1904.

THE diphenylamine derivatives obtained by reduction of the condensation products of *p*-nitrochlorobenzene with aniline (NO₂:SO₂H:Cl=1:3:4) with *m*-phenylenediamine, *m*-toluylenediamine or chloro-*m*-phenylenediamine, are found, by reason of their easy oxidation, to be well suited to the dyeing of leather, especially chrome-dyed leather, on which greyish-blue to blue-black shades are produced when the leather is treated with an alkaline solution of one of the above compounds together with an oxidising agent such as hydrogen peroxide or a chromate. The resulting tanned leather is dyed by this method grey or greenish-black shades. In either case the dyeings can be toned by the use of a suitable dyestuff.—T. F. B.

Printing Plates; Manufacture of Plastic Compositions for use in the Production of —, but also applicable to other purposes. L. Collardon, Leipzig. Eng. Pat. 27,090, Dec. 12, 1904.

THE plastic mass is obtained by moistening insoluble casein or albumin, mixing the same thoroughly with a hardening medium, and then submitting it to pressure and heat. As moistening agents, water, strong ammonia, and organic compounds not too easily volatilisable are suggested, and as hardening media, tannins, formaldehyde, hexamethylenetetramine, chromates, bichromates, &c. To counteract any alkaline reaction of the hardening media, solid acid bodies, and acid phosphates, boric acid, chromates, &c., may be added to the casein. It is also advisable to add organic bodies, which melt at temperatures above 100° C., and act as solvents on the surface of the casein, and albumin, and facilitate adhesion. The density of the mass may be increased by the addition of filling materials such as metallic oxides, silicates, &c., or the mass may be softened by the addition of suitable

rium sulphate, magnesia, chalk, kaolin, &c. The also include the use of this plastic mass for the tecture of printing and impressing dies.—W.C.H.

I.—ACIDS, ALKALIS, AND SALTS, AND NON-METALLIC ELEMENTS.

ferrocyanic Acid; Compounds of Sulphuric Acid —. *Sulphonic Substitution in the Molecule of plex Cyanides. Oxyferrocyanides.* P. Chrétien. *ptes rend.* 1905, 141, 37—39.

turated solution of hydroferrocyanic acid in strong ic acid be gradually diluted with water and left to rhombohedral crystals are deposited, having mposition $H_4Fe(CN)_6 \cdot 7H_2SO_4$; if the addition ter be continued till a permanent turbidity the crystals are needles, and their formula is $(CN)_6 \cdot 5H_2SO_4$. These two substances readily disso- moist air.

hydroferrocyanic acid be dissolved at 100° C. in sulphuric acid, the solution on cooling deposits a, which, when exposed to air on a porous tile, phuric acid. The resulting substance crystallised alcohol has the composition $H_4Fe(CN)_6 \cdot H_2SO_4$; stability in moist air and its other reactions to be really the hydrate of a sulphonic acid $N_6 \cdot HSO_3 \cdot H_2O$. If for ordinary sulphuric acid e substituted a mixture of this with fuming sul- acid, similar treatment gives two substances, one the composition $Fe(CN)_6SO_3$, the other being the ic acid just mentioned. These bodies are formed

two successive reactions $2Fe(CN)_6H_4 + S_2O_7 \cdot H_2 + 2Fe(CN)_6(SO_3)H_2$ and $2Fe(CN)_6(SO_3)H_2 + O = 6(SO_3H)H_2 + Fe(CN)_6SO_3$. The action of alkalis on er substance results in the formation of hydroxy- anides:— $Fe(CN)_6SO_3 + 3H_2O = Fe(CN)_6(OH)_3 +$ Sodium hydroxide yields a double salt, crystal- from alcohol, $Fe(CN)_6(OH)_3Na_2 \cdot SO_4 \cdot Na_2$; while carbonate forms barium sulphate and a crystal- salt $(Fe(CN)_6OH)_2Ba_3 \cdot 4H_2O$.—J. T. D.

ising; Theory of —. G. Bodländer and R. cas. *Z. angew. Chem.* 1905, 18, 1137—1141.

equilibrium point of the reaction $K_2CO_3 + Ca(OH)_2 + 2KOH$ depends on the relative solu- of calcium hydroxide and calcium carbonate. a hydroxide dissolves in water till the product $2OH$ has reached a constant value k_1 . If the

already contains hydroxyl ions, the value k_1 will led by the solution of a smaller amount of calcium ide than if it does not, i.e., calcium hydroxide soluble in a solution of alkali hydroxide than in Similarly when a solution is saturated with carbonate, $C_C \times C_{CO_3}$ has a constant value k_2 , alkali carbonate in solution diminishes the solubility cium carbonate. Thus as the reaction above is from left to right the solubility of calcium ide gradually diminishes and that of calcium ate increases, and equilibrium occurs when the ular solubilities" are alike, i.e., when C_C is the

or the hydroxide as for the carbonate. At that then $k_1/C^2_{OH} = k_2/C_{CO_3}$, or $C^2_{OH}/C_{CO_3} = k_1/k_2 = k_3$

this shows that the concentration of the carbonate ceases as the square of that of the hydroxyl ions; more concentrated the solution of hydroxide y produced, the smaller the proportion of the l carbonate causticised, in other words the poorer ld. Lunge's figures illustrate this, and the authors, eriments conducted by shaking lime with solutions l carbonate and hydroxide at 18° and at 25° C., ililibrium was attained, found that as the final ture of sodium hydroxide increased from N ly 3N, the yield diminished from 94 per cent. per cent. and 87 per cent. respectively. The e temperature on the equilibrium can be predicted: ion which evolves heat will not proceed so far, one

which absorbs heat will proceed farther, as the tempera- ture is raised. In very dilute solutions the reaction $Na_2CO_3 + Ca(OH)_2 = CaCO_3 + 2NaOH$ evolves heat, but in more concentrated solutions absorbs it; so that as usually practised, elevation of temperature favours the reaction, though but slightly. It has the further advan- tage, however, of increasing the speed of reaction, and thus accelerating the attainment of equilibrium. An application of the phase rule presents itself in considering the causticising process. There are four constituents, sodium hydroxide, calcium carbonate, calcium hydroxide and water; and four phases, solid lime, solid calcium carbonate, solution and vapour. It is well known that loss of alkali occurs through its being carried down with the lime. If this be (as is usually assumed) in the form of Gaylussite, $CaCO_3 \cdot Na_2CO_3 \cdot 5H_2O$, it forms a fifth phase, and this loss can only occur at one definite con- centration, thus a mode of working may be devised which will prevent the formation of gaylussite; but if it be as a solid solution, then there are only four phases, and the loss of alkali may occur at various concentrations. The employment of dilute solutions for the sake of high yields involves the concentration of these dilute solutions; and to avoid this, other hydroxides instead of that of calcium may be sought. The relative solubilities of magnesium hydroxide and carbonate are still more unfavourable than those of the corresponding calcium compounds; but barium and especially strontium compounds are much more suitable, for while k_3 in the case of calcium works out to 2350, its value in the case of strontium is 195000. Experiments, similar to those previously quoted, gave with strontium yields of 99.5 and 99 per cent. against 83 and 87 per cent. with calcium. With strontium elevation of temperature is prejudicial to completeness of causticising. A practicable method of employing strontium would be to causticise with lime as far as possible, and to pour off and treat the clear liquid with strontium hydroxide.—J. T. D.

Potassium Sulphate; The Process of Causticising —. J. Herold. *Z. Elektrochem.* 1905, 11, 417—430.

THE equilibrium-constant of the reaction $Ca(OH)_2 + SO_4'' \rightarrow CaSO_4 + 2OH'$, since the concentrations of the calcium hydroxide and sulphate, in contact with the solid sub- stances, are constant, has the form $k = C^2_{OH}/C_{SO_4}$, and can be calculated (if the dissolved salts be supposed com- pletely dissociated) from the solubilities of calcium hydroxide and calcium sulphate. In concentrated solutions the reaction is more complex, from the formation of syngenite, $K_2Ca(SO_4)_2 \cdot H_2O$, and the constant has the form $k' = C_{OH}/C^2_{SO_4}$. In the first case, the reaction pro- ducing hydroxyl ions (causticising) will be favoured by dilution; in the second, on the other hand, by evaporation and consequent concentration.

Calculation of the solubilities of calcium sulphate and hydroxide at high temperatures, using van't Hoff's formula for extrapolation, seemed to indicate that good results would be obtained by causticising at high tem- peratures under pressure. But some of the deductions from the figures so obtained threw doubt on their accuracy, and the author undertook some direct determinations of the solubility of calcium hydroxide, the results of which were:—

Temp. °C.	1 litre contains grms. CaO.	
120	0.314 0.309 0.301 0.167	mean 0.305
150	0.171 0.169 0.088 0.083 0.080	mean 0.169
190		mean 0.084

Direct experiments on causticising were now carried out by heating together potassium sulphate and lime, and also potassium hydroxide and gypsum (or anhydrite for temperatures above 100° C.) till equilibrium was approximately attained, and determining the composition of the resulting clear liquid. The general trend of the results at each temperature is that k lessens in value as the concentration increases; but k can only be cal-

culated from the total concentrations of the salts, for their degrees of dissociation are not known so as to furnish the ionic concentrations. The difference is most marked at the higher temperatures. While the experiments at higher temperatures show that at equal dilutions the production of potassium hydroxide goes farther than at 70° C., yet the difference is not very marked, while on the other hand, the results at 0° C. suggest that it may be possible to carry out the process at this temperature profitably on the industrial scale. Though the figures suggest that the formation of potassium hydroxide goes farthest at low concentrations, yet these are only proportional or relative amounts, and the absolute amount obtainable at a higher concentration may be equally great, and more economically separable. This separation will possibly be better carried out by freezing than by boiling down; for as the temperature falls below 2-6° C., both ice and potassium sulphate separate, one at the surface and one at the bottom.—J. T. D.

Ammonia; Reactions in Liquid ——. E. C. Franklin, J. Amer. Chem. Soc., 1905, 27, 820—851.

Of all known solvents liquefied ammonia most closely resembles water in general physical properties, and the author draws attention also to the close analogy between the relations of the acid amides, metallic amides, and the metallic derivatives of the acid amides to ammonia, on the one hand, and the relations of the ordinary oxygen acids, bases and salts to water, on the other. In view of this general similarity, the author proposes the names *ammono-salts*, *ammono-bases* and *ammono-acids* for the ammonia derivatives bearing to ammonia the relations which ordinary salts, bases and acids (or *hydro-salts*, *hydro-bases* and *hydro-acids*) bear to water. Ammono-acids and ammono-bases dissolved in liquefied ammonia react to form ammono-salts. For example, acetamide and potassium amide form potassium acetamide: $\text{CH}_3\text{CONH}_2 + \text{KNH}_2 = \text{CH}_3\text{CONHK} + \text{NH}_3$ or $\text{CH}_3\text{CONH}_2 + 2\text{KNH}_2 = \text{CH}_3\text{CONK}_2 + 2\text{NH}_3$; whilst urea and potassium amide form potassium carbamide: $\text{CON}_2\text{H}_4 + \text{KNH}_2 = \text{CON}_2\text{H}_3\text{K} + \text{NH}_3$, or $\text{CON}_2\text{H}_4 + 2\text{KNH}_2 = \text{CON}_2\text{H}_2\text{K}_2 + 2\text{NH}_3$. Some metallic salts are decomposed in liquefied ammonia in a manner analogous to hydrolytic decomposition in water (see François, this J., 1900, 80; Joannis, this J., 1903, 49; and Vigouroux and Hugot, this J., 1903, 887). For this class of reactions, the designation *ammonolysis* is proposed, analogous to hydrolysis. Salts of the heavy metals when dissolved in liquefied ammonia react with the soluble alkali amides to form amides, imides or nitriles of the heavy metals. Silver amide, lead imide and mercuric and bismuth nitriles, which are all explosive compounds, were thus prepared, in accord with the following equations:—(1) $\text{Ag}_2\text{NO}_3 + \text{KNH}_2 = \text{AgNH}_2 + \text{KNO}_3$; (2) $\text{Pb}(\text{NO}_3)_2 + 2\text{KNH}_2 = \text{PbNH}_2 + 2\text{KNO}_3 + \text{NH}_3$; (3) $3\text{HgI}_2 + 6\text{KNH}_2 = \text{Hg}_3\text{N}_2 + 6\text{KI} + 4\text{NH}_3$; (4) $\text{BiBr}_3 + 3\text{KNH}_2 = \text{BiN} + 3\text{KBr} + 2\text{NH}_3$. These ammono-bases are insoluble in liquefied ammonia, but dissolve readily in solutions of ammonium salts in liquefied ammonia. They are decomposed by the action of water, ammonia being evolved. In many cases, when an excess of the metallic salt is used, ammono-basic salts are produced in an analogous manner to the formation of ordinary basic salts in aqueous solutions. Ammono-basic mercuric iodide, Hg_2NI , (see François, this J., 1900, 80, 463), ammono-basic mercuric bromide, Hg_2NBr , ammono-basic mercuric chloride, $\text{Hg}_2\text{NH}_2\text{Cl}$, the known "infusible white precipitate," and ammono-basic lead iodide, $\text{Pb}_2\text{NI.NH}_3$, were prepared in this way. The author considers that all the so-called mercuri-ammonium compounds may be regarded as belonging to one of three classes of ammonia derivatives: first, ammono-basic compounds; second, mercuric salts with ammonia of crystallisation; and (3), mixed ammono-basic and hydro-basic compounds. Nessler's precipitate (see François, this J., 1900, 463) for example is considered to be a mixed ammono-basic and hydro-basic mercuric iodide, $\text{NH}_2\text{Hg}_2\text{O.Hg.I}$. Certain ammono-bases, for instance, the silver, aluminium, copper and lead compounds dissolve in excess of potassium amide in liquefied ammonia solution just as many metallic hydroxides and oxides

dissolve in aqueous solutions of potassium hydroxide. A lead compound prepared in this way had a composition corresponding approximately to the formula PbNKK_2 or $\text{PbNH}_2\text{.NHK}$. (See also this J., 1899, 180; 1904, 474.)—A.S.

Potassium Chlorate; Decomposition of ——. by Hydrochloric Acid. E. Davidson. Z. angew. Chem., 1905, 18, 1047—1051.

The author has examined the decomposition of potassium chlorate by hydrochloric acid in dilute solution, taking every precaution to exclude air, and determining after varying intervals of time the amounts of chlorate free (by iodide and thiosulphate, and also by arsenic acid). His conclusion is that the reaction is unimolecular, the active substance being the potassium chlorate; however its concentration be varied, the same value of the affinity-constant, is obtained, and the same time requisite for the reaction to proceed half-way to completion. Rise of temperature accelerates the reaction in such a way that the speed of reaction increases in a constant ratio with equal intervals of temperature-rise. The presence of potassium iodide during the reaction accelerates it; this effect is catalytic, for the effect of varying the concentration of potassium iodide is not in agreement with Guldberg and Waage's law. The speed of reaction increases with increase of the concentration of hydrochloric acid, and is only measurably rapid when a considerable excess of hydrochloric acid is present. The effect of change of concentration of hydrochloric acid, however, is not consistent with the reaction being bi- or tri-molecular. The author's view is that the effect of the hydrogen of the hydrochloric acid is to push the equilibrium of the reaction $\text{HClO}_3 \rightleftharpoons \text{H}^+ + \text{ClO}_3^-$ towards the left; and as undissociated chloric acid is decomposed and equilibrium disturbed, more is formed from the ions till decomposition is complete. The energetic decomposition of solid potassium chlorate, compared with the sluggish reaction in aqueous solution in which the anion ClO_3^- exists, favours this view. The experiments do not afford material for deciding whether the chloric acid gives off all its oxygen at once, which then reacts on the hydrochloric acid, or whether hypochlorous acid is formed intermediate. Probability is in favour of the latter view, however, though the actual isolation of hypochlorous acid has not yet been accomplished.—J. T. D.

Ferrie Sulphate; Molecular Transformations of Hydrochloric Acid. A. Recoura. Comptes rend., 1905, 141, 109.

When an aqueous solution of ferrie sulphate is left to evaporate, two phases occur in the process. At a certain concentration, the basic sulphate $6\text{Fe}_2(\text{SO}_4)_3\text{.Fe}_2(\text{SO}_4)_3$ (this J., 1905, 801), deposits, leaving acid sulphate in solution; then the acid liquid and the basic solid combine, forming a yellow solid of composition $\text{Fe}_2\text{O}_3\text{.3SO}_3\text{.9H}_2\text{O}$. This substance, however, is not perfectly homogeneous. If the perfectly dry substance be very finely powdered then dissolved in a very small amount of water, and stirred out with a brush in a thin layer on glass plates, it becomes a perfectly white solid, absolutely homogeneous, having the same composition $\text{Fe}_2(\text{SO}_4)_3\text{.9H}_2\text{O}$. It differs from the yellow salt in being very slowly dissolved by water, soluble without decomposition in alcohol, and stable in moist air. The separate identity of the two substances, however, does not persist in their aqueous solutions.

—J. T. D.

Thermite Process; Binary Metallic Compounds prepared by the ——. A. Colani. Comptes rend., 1905, 141, 33—35.

The author has prepared a number of compounds (sulphides, phosphides, silicides, &c.) by firing a mixture of the metalloid, the metallic oxide, and aluminium. Sometimes the oxide of the metalloid is used; and copper oxide may be added to increase, or copper filings to lessen the intensity of the reaction. The compounds are, however, for the most part contaminated by aluminium and sometimes by iron, and many trials are sometimes required before a satisfactory fusion is obtained.—J. T. D.

Hydroxide in Presence of Sodium Carbonate; Metric Determination of —. K. Novotny. *U.S. Pat.* 860.

Cyanogen Mud. A. Hand. *U.S. Pat.* 835.

ENGLISH PATENTS.

Processes of the Alkaline Earths and Sulphates of the Alkalies; Process for Reducing — to Sulphides for Reducing Metallic Oxides to Metals. C. Calastretti. Milan, Italy. Eng. Pat. 13,565, June 15, 1904. Under Int. Conv., June 20, 1904.

Sulphites; Manufacture of Stable —. J. Y. J. London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 15, Oct. 31, 1904.

Second Addition, dated Nov. 7, 1901, to Fr. Pat. 3 of 1904; this J., 1905, 333.—T. F. B.

Acid; Processes and Apparatus for Manufacturing —. E. A. and J. G. Behrens, Bremen, Germany. Eng. Pat. 13,981, June 20, 1904.

U.S. Pat. 343,903 of 1904; this J., 1904, 1089.—T. F. B.

UNITED STATES PATENTS.

Acid Manufacture; Catalytic Substances for — Process of Making same. R. Knietzsch, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany. U.S. Pat. 794,512, July 11, 1905.

U.S. Pat. 10,729 of 1901; this J., 1902, 548.—T. F. B.

Acid Anhydride; Catalytic Apparatus for Making —. M. Schroeder, Düsseldorf, Germany. Assignor to New Jersey Zinc Co., N.J. U.S. Pat. 793,543, July 27, 1905.

Apparatus comprises a receptacle containing a number of compartments, each having a body of contact resting on a screen. Between the separate compartments of contact material are arranged mixing diaphragms, having a central restricted aperture, of the shape of a truncated frustrum of a cone, so that the gases are easily mixed on their passage, and brought to a certain temperature. (Compare U.S. Pat. 789,634, 1905; this J., 1905, 619.)—E. S.

Solutions; Electrolytic Decomposition of —. L. Larchar, Assignor to Penobscot Chem. Fibre Co. U.S. Pat. 793,138, June 27, 1905. *XI A.*, page 850.

Carbon Dioxide; Process of Absorbing —. A. Nultze, Charlottenburg, Germany. U.S. Pat. 797, July 4, 1905.

Processes described in the main patent, and in the second addition thereto of Aug. 18, 1904 (this J. 1905, 90), are claimed as also applicable to vanadium ores.

FRENCH PATENTS.

Processes of Copper, Zinc, Cadmium, Silver, Nickel, and Tungsten; Process of Obtaining the — by the Wet Way, by direct Extraction. D. Lance. *U.S. Pat.* 865, Jan. 9, 1905, to Fr. Pat. 342,865, Jan. 4, 1904 (this J., 1904, 1032).

Processes described in the main patent, and in the second addition thereto of Aug. 18, 1904 (this J. 1905, 90), are claimed as also applicable to vanadium ores.

In precipitating the solutions obtained, magnesia preferably, or another base capable of affording a soluble salt with the acid used to effect the solution, is employed. The hydroxides of the several metals are precipitated fractionally from the boiling solution. The first precipitate includes the iron present, together with a certain proportion of nickel, and this precipitate may be washed and reduced and fused to obtain an alloy of iron and nickel, the proportion of nickel in which may be reinforced by addition from the second precipitate, containing wholly or chiefly nickel hydroxide. The precipitates generally are washed by a hot ammoniacal solution during passage of ammonia gas in excess, with or without the presence of amines.—E. S.

Leucite, or Minerals containing Leucite; Disintegration of —, by treatment with Alkalies. A. Piva. Fr. Pat. 351,338, Feb. 7, 1905.

LEUCITE, or an ore containing it, in fine powder, is placed in an autoclave with a concentrated solution of potassium or sodium hydroxide, and live steam is passed in under a pressure of from 20 to 25 atmospheres, and at a temperature exceeding 200° C. Alkali aluminates and silicates are thus obtained, which yield alumina and an alkali carbonate on suitable treatment.—E. S.

VIII.—GLASS, POTTERY, AND ENAMELS.

Glassware; Chemical —. P. H. Walker. J. Amer. Chem. Soc., 1905, 27, 865—875.

The glassware was subjected to a series of tests including solubility determinations, and mechanical tests as regards breaking or cracking in consequence of changes of temperature. The following kinds of glassware were examined:—(1) Flasks and beakers of Kavalier (Bohemian) glass; (2) Flasks and beakers of Weber's resistance glass, also known as Greiner and Friedrichs' resistance glass, and bearing the permanent trade mark "R"; (3) Flasks and beakers of Wiener Normal glass, bearing the trade mark "Wiener Normal Geräte Glas"; (4) Beakers of Thüringian glass; (5) Beakers, flasks and Erlenmeyer flasks of Jena glass, bearing the trade mark "Schott and Gen. Jena"; (6) Beakers of "Nonsol" glass, bearing the trade mark "Nonsol W. T. Co."; (7) Beakers, flasks and Erlenmeyer flasks of laboratory glassware of American manufacture; (8) Beakers of Bohemian Normal glass from an American dealer; (9) Beakers and flasks of resistance glass of Vercin. Fabr. für Laboratoriumsbedarf; (10) Beakers and flasks of "F.Z." resistance glass, bearing the trade mark "F.Z."; and (11) Bohemian glass beakers from an American dealer. Analysis showed that those glasses bearing permanent trade-marks, viz., Nos. (2), (3), (5), (6), and (10), were all borosilicate glasses in which a portion of the lime had been replaced by zinc, whilst the other glasses were alkali-lime silicates. The zinc borosilicate glasses and the Kavalier (Bohemian) glass gave the best results in the different tests. Of the borosilicate glasses the Wiener Normal glass (No. 3) was the least resistant to reagents, and its properties more nearly resembled those of the alkali-lime silicate glasses. It was observed that with the same variety of glass, the beakers were more resistant to reagents than the flasks. The American alkali-lime silicate glasses were, in general, of very poor quality.—A. S.

Shrinkage on Firing; Investigations on —. R. Lucas. Z. physik. Chem. 1905, 52, 327—342.

REFRACTORY oxides, such as alumina, magnesia, beryllium oxide, titanite acid, iron oxide, and the oxides of the rare earths, when heated to high temperatures contract in a marked degree. The contraction is greater, the higher the temperature, and it is remarkable that practically no alteration in the absolute weight occurs. The contraction on firing is distinct from the contraction on drying. The method of experiment was to work some fine soft powder of the above-mentioned bodies into

a kneadable mass with a little water, and to press the mass out into a cylindrical thread, which was dried in the air, and then as far as possible by heat, and the dried cylinder cut into smaller rods, the dimensions of which were measured before and after burning by means of a micrometer. The course of the shrinkage at different temperatures was followed in many experiments in an electrical platinum resistance furnace, and the temperatures determined by a platinum-platinum-rhodium thermo-couple. Before the experiments, the heat distribution in the inner tube was determined, and zones of constant temperature located. For further experiments two other furnaces were used, one composed of magnesia and graphite, and the other of an iridium tube, and the temperatures were measured by comparing the light given out with that given by a Nernst incandescent lamp, and calculating the temperature in degrees centigrade from the deflections of the galvanometer in the circuit.

The author found that the contraction depended upon the rate of heating. When the substances are brought slowly to a given temperature, the contraction is always less than when the bodies are heated rapidly, and the difference increases up to about 950° C., when it amounts to about 4 per cent. (linear). At higher temperatures the difference slowly decreases, and at very high temperatures entirely disappears.

The contraction of the materials experimented upon was not the same in all directions, for when placed in a horizontal position, the contraction in the direction of length was always found to be smaller than the linear contraction in a vertical direction, and the difference increases with increase of temperature.

The sharp falling off of the contraction curve appears to be characteristic of contracting bodies. Though the position of the initial and final points of the shrinkage on firing is different for individual bodies, the character of the individual curves is essentially the same.

With regard to the effect produced by the length of time of burning upon the contraction, it was found that a rod contracted very rapidly at first under the influence of heat, but that afterwards only a relatively small alteration occurred when a definite temperature was maintained for a longer period. Thus, a rod burned at 1170° C. for one hour contracted from 100 to 80.4, whilst a further 12 hours' heating at the same temperature caused a further contraction of only 0.7. A rod that has been burned for a long time at about 1090°, on heating further to 1100° C. shows a diminution of the power of contraction.

The strength of these substances is increased owing to the contraction.

Shrinkage on firing on the one hand gives strength to a body, and on the other causes a marked diminution of volume, without any essential alteration in the absolute weight; hence the contraction can only be explained by the fact that the bodies possess hollow spaces, which under the influence of heat contract. This explanation is confirmed by actual determinations of porosity, hence the amount of shrinkage depends upon the degree of porosity. Shrinkage being dependent upon the diminution of the hollow spaces, it may be assumed that elastic forces are at work, which tend to reduce the free surfaces to a minimum, and that the body must be in a condition to answer to a contractive force—in other words a cementation of individual particles occurs. These conditions are satisfied by amorphous bodies. Since kaolin contains two molecules of water of crystallisation, it might appear to be an exception; but hydrated bodies that have been heated sufficiently to drive off this combined water, behave like amorphous substances, and shrinkage is shown by experiment to occur in kaolin only when the temperature has risen above the point of dehydration. A decrease of specific volume, shown by an increase in density, occurs on heating many bodies (e.g. amorphous magnesia) to high temperatures, at which polymerisation, in other words rearrangement of molecules, takes place, causing a contraction of the free surface. Assuming then that bodies that shrink are in an amorphous condition, then, at all temperatures, capillary forces come into play and must tend to diminish the surface, and gradually diminish the porosity. At ordinary temperatures the

internal tension is too great to allow this contraction occur to any marked degree, but with rise of temperature the tension decreases and the rate of contraction correspondingly increases.—W. C. H.

Glaze; Blood-red Chinese —. C. Otsuki. Z. ang. Chem. 1905, 18, 1054—1055.

ANALYSIS of this glaze carefully separated from the underlying body gave the following results:—

SiO₂, 59.58 per cent.; SnO, 0.32; CuO, 1.20; PbO, 8.20; Fe₂O₃, 1.39; Al₂O₃, 8.38; CaO, 11.11; MgO, 1.70; K₂O, 2.74; Na₂O, 5.27 per cent.; and MnO, trace. This would give a formula (2.0 RO + 0.04 Fe₂O₃) 0.4 Al₂O₃ 5SiO₂, where RO is 0.5 SnO, 3.7 CuO, 9.0 PbO, 48.0 CaO, 10.0 MgO, 7.1 K₂O, 22.0 Na₂O. Such a glaze can be composed of a mixture of silica, 175.0 grms.; stannic oxide, 0.32; copper carbonate, 5.4; lead carbonate, 29.0; calcareous carbonate, 57.0; potassium bicarbonate, 17.0; sodium bicarbonate, 34.0; ferric oxide, 4.0; alumina, 2.0; and magnesia, 5.0 grms.—J. T. D.

ENGLISH PATENT.

Silica [Quartz Glass]; Impts. in the Working of Fused Silica —. J. F. Bottomley, Wallsend-on-Tyne, and J. Paget, North Cray, Kent. Eng. Pat. 18,437, Aug. 15, 1904.

THE specification contains descriptions of various forms of electrically heated furnaces for fusing silica, which consist essentially of a vessel containing sand, with an internal resistance core, which can be withdrawn from the fused mass, to allow of the further working of the plastic material. The initial separation of the core is effected by allowing the formation of a small quantity of gas round the surface of the core (graphite). After fusion of the material and withdrawal of the internal core, which can be separated from one or both electrodes, the plastic cylinder may be shaped by one or more processes of drawing, blowing, or mechanical pressing. Forms of apparatus are described to allow of the rotation of the heating core and surrounding material, about a longitudinal or transverse horizontal axis for the processes mentioned. A plastic cylinder glazed externally may be produced either by limiting the material surrounding the core so that the whole is within an external jacket, or by heating it in an electrically heated chamber, prior to shaping the mass. By closing one end of the plastic cylinder, and pressing the other round a refractory nozzle, to form a gas tight seal, and by introducing compressed air or gas through the nozzle, the cylinder may be drawn into tubing or into shape in a mould.—W. C. H.

FRENCH PATENT.

Tiles of Ceramic Paste or Cement; Apparatus for Applying and Distributing Colouring Matters for the Manufacture of Enamels —. Erste Schattauer Thon- und Glasfabriks-Act.-Ges. (vorm. C. Schlimp). Fr. Pat. 354,900, Feb. 3, 1905.

THE apparatus consists, for each colouring matter, of two plates enclosing a groove, and having open spaces, which correspond with those of the network in which the colouring matter is to be distributed, and designed so that those of the upper plate are used for the addition of the said colouring matter, which is fed on to the apparatus and falls into the open spaces of the network, while the lower plate or curtains mounted in the open spaces of the upper plate, and also distributing reglettes mounted obliquely in the spaces of the net-work.—W. C. H.

IX.—BUILDING MATERIALS, CLAY, MORTARS, AND CEMENTS.

Building Materials; Determination of Porosity of Mortars —. W. Thörner. Chem.-Zeit., 1905, 29, 744—746.

IN 1884 (see Eisen. u. Stahl, 1884, 4, 594) the author described a simple method of determining the porosity and specific gravity of coke and charcoal. Two samples

menometers were used of the form shown in Fig. 1; smaller held about 100 c.c. up to the zero mark on the measuring tube, and the latter about 200 c.c. The former filled with liquid to about the zero mark, and when the temperature was constant, the volume was noted. A fixed quantity of finely powdered, that is pore-free, substance was carefully shaken down into the apparatus, the volume then read off; the difference between the readings, gives the volume of the substance taken, and divided into the weight in grammes gives the specific

Fig. 2.

Fig. 3.

ty. A small weighed lump of the substance, about 12 mm. wide, was covered with distilled water in a jar, heated to boiling, and put aside to cool. This was then drained in a funnel, and then slowly slid into the apparatus; the difference between the initial and final readings of the instrument gives the volume of the substance taken, and the specific gravity of the substance is the quotient obtained by dividing the weight of the substance taken by the observed volume of substance and pores.

Porosity of building materials is often distributed unequally through the mass, and in order to obtain accurate average values, the author has devised the following larger apparatus, which is useful for substances other than building materials. The thick-walled bottle (Fig. 2) holds about 800 c.c., is covered with a dome-shaped cover H, provided

with some form of locking ring, and carrying a thermometer J, and an overflow tube L, with stop cock K. Near the bottom of the bottle is fused on an upright branch tube B, into which a measuring tube F is ground, having two widenings C and D, between which the tube is divided into tenths of a c.c. for 50 c.c. A stop-cock E, with a funnel-shaped opening T is placed above the bulb D. A porosity determination is made, as follows: The stop-cocks E and K being open, the bottle A is filled with distilled water, through the funnel T, until water begins to flow out from L, and stands at the zero point. The apparatus is then tilted, until the bulb C is completely and D partially filled with the water, when E is shut to prevent the return of the water, on again standing the volumenometer upright. The cover is removed, and large pieces of the substance, up to about 250–500 grammes, are put into A, the pieces having previously been heated to boiling in water and cooled and drained. The cover is put on again, the cock K being shut, and a small measuring cylinder placed under L. The cock E is opened, and by carefully opening K, liquid is allowed to slowly refill A, till water just escapes from L, when K is quickly shut, and the volume displaced read off directly in c.c. on the measuring tube.

A simpler and cheaper form of the apparatus is shown in Fig. 3, and consists of a thick walled bottle, with a dome-shaped cover provided with an upright tube expanded into a funnel-shaped opening at the top. Up to the mark M the apparatus holds 1000 c.c. About 500–800 grms. of the sample, in large lumps, soaked with water, &c., as before, are used, and put into the bottle. One of the following methods can then be used:—1. The bottle and sample are weighed on a balance, and the apparatus filled up to the mark with distilled water and again weighed. The weight of water thus found subtracted from 1000, gives the volume of water displaced by the porous substance, in other words, the volume, in c.c. occupied by the body and pores. 2. A litre-flask filled with water is weighed, and the volumenometer filled up to the mark with some of the water, and the rest and the flask again weighed the difference, subtracted from 1000, gives the volume of water displaced. 3. The water necessary to fill up to the mark is measured direct with a measuring cylinder, and the final amount with a burette. This deducted from 1000 gives the volume displaced. In all cases, the rest of the calculation is the same as before. The sources of error in the apparatus are that a little liquid will always remain adhering to the soaked sample, and that a small portion of the absorbed liquid may escape from the mouth of the pores; but for technical purposes it gives sufficiently accurate results. The following table gives the porosity of some building materials and shows how greatly it varies, and how advisable it is to determine beforehand the porosity of materials to be used, as the permeability of walls is so important from the point of view of health.

	Specific Gravity.		Pore-volume in 1000 grms. of Material.	Substance Volume in 1000 grms. of Material.	Volume of 1000 grms. of Porous Substance.	Weight of 1000 c.c. of Porous Substance.
	Substance without Pores.	Porous Substance.

ENGLISH PATENTS.

Non-conducting Material; Improved Heat —. G. Müller, Kiel, and E. Jarck, Hamburg, Germany. Eng. Pat. 16,940, Aug. 2, 1904.

TWENTY-FIVE per cent. of clay, 10 of asbestos fibre, 25 of silicious marl, 5 of vegetable fibre, 17 of ground cork, 3 of aluminium sulphate, 4 of starch flour, 1 of yeast and 10 of water are intimately mixed together in a mixing machine and allowed to ferment. The resulting moist and spongy mass is either applied directly to the surfaces to be insulated or else compressed in moulds to form insulating shells. In applying these latter, the surfaces to be protected are first given a coating of the moist paste, on which the shells are then pressed, any joints between the shells being also filled in with the paste. The compound is stated to be capable of resisting temperatures up to 500° C.—A. G. L.

Composition for Building and other Purposes; Manufacture of —. E. Laine, Brussels. Eng. Pat. 8024, April 14, 1905.

IN this process, dolomite and freshly calcined magnesia form the basis, but grinding and sifting, even through silk does not give the material in a sufficiently fine or pure state of division for the necessary reaction to take place to form the oxychloride. The material is said to be obtained in a very finely divided state, and free from iron, lime or manganese salts by precipitation, and is then well washed and calcined. To mould it into the required shapes, the material is mixed with a composition of 3 volumes of pure magnesium chloride to 1 volume of alcohol, denatured by acetone, to which cellulose has been added and containing in solution a variable proportion of gum elemi, gum sandarac or the pure resin of *pinus larix*. This is said to yield a white homogeneous paste.—W. C. H.

Marl, Clay or like Material; Impts. in Separators and Grinding Mills used in the Treatment of —. J. S. Wilkes, Sutton Coldfield. Eng. Pat. 17,563, Aug. 12, 1904.

THE claim is for an inclined revolving screen with differently meshed portions, the coarsest mesh being at the lower end. The screen is provided with internal longitudinal bars, carried on brackets and serving to break up the material. The screen is carried, either by an internal shaft attached by brackets, or on external anti-friction rollers. A pair of tapered horizontal crushing rolls, placed below the lowest portion of the screen, serves to break up the lumps of clay passing through.—W. H. C.

Cements; Manufacture of Keen's or other —, having a Gypsum Base. T. J. Armstrong, Carlisle. Eng. Pat. 1457, Jan. 25, 1905.

RAW gypsum in a fairly dry state, preferably gypsum that has lain in the air for a few days after having been raised from the mine, is powdered and moistened with a solution of what is termed "a supplementary salt." The damp mass is formed into cakes, which are calcined as usual, the product then being reduced to powder. In this way an intimate mixture of the salt and gypsum is obtained with only one calcining.—A. G. L.

FRENCH PATENTS.

Mortars; Binding Material for — and Process of Manufacturing the same. See Anon. de Fondations par Compression Mécanique du Sol. Fr. Pat. 349,866, April 18, 1904.

THE binding material is made by burning together chalk or cement and silica, silicates, or even carbonates. The materials are crushed, dried and finely powdered separately, and only mixed at their entry into a horizontal rotating kiln, made of a steel tube lined with silica and containing a number of flints, which serve to mix and powder the material during the burning. Gas-firing is used for the kiln. The product emerges ready ground for use.—A. G. L.

Non-conducting Material; Manufacture of Heat —. C. Henke. Fr. Pat. 351,192, Feb. 1, 1905.

THE material is made from the dust obtained in purifying blast-furnace gases. The dust is first dried and powdered. It is applied either in the form of powder or after moulding into shells or pads, &c.—A. G. L.

X.—METALLURGY.

Steels; Classification and Properties of Ternary —. L. Guillet. Comptes rend., 1905, 141, 107—10.

IN regard to their microstructure, all these steels (niobium, manganese-, chromium-, tungsten-, molybdenum-, silicon-, vanadium-, titanium-, tin- and cobalt-steels) may be grouped into:—(1) Pearlitic steels, (2) martensitic steels, (3) steels containing γ -iron, (4) steels containing carbide, (5) steels containing graphite. The properties of pearlitic steel depend on the nature of the third substance introduced into the iron-carbon alloy. Martensitic (and those containing troostite) have a high tensile strength and elastic limit, are hard and difficult to machine. Carbide steels are only found in the cases of chromium-, tungsten-, molybdenum-, and vanadium alloys, and the hardness of the granules of carbide varies with the metal. Steel. As a rule the micrographic examination of steel allows conclusions to be drawn as to its properties and industrial applications, though this is, unfortunately, not the case with the largest class, the pearlitic steels.—J. D.

Rivets; Effect on Mechanical Properties of Iron and Steel used for —, produced by the Operation of Riveting. C. Frémont. Comptes rend., 1905, 141, 39—40.

MECHANICAL tests were made of Swedish iron and steel of six varieties of steel, each being tested (1) in its original state, (2) after being heated to the temperature necessary for riveting, but not mechanically treated, (3) after being heated and subjected to compression and then tested under tension exactly like a rivet. The tensile strength, elastic limit, and reduction of area indicated in the case that the metal was improved by the treatment; this improvement was not simply due to hardening, for the fragility was not increased in any case.—J. T.

Iron; Action of Slightly Alkaline Waters on —. C. H. Cribb and F. W. F. Arnaud, Analyst, 1905, 30, 225—242.

THE authors find that, by immersing a strip of iron plate in 100 c.c. of water and keeping the temperature at a temperature of 100° C. for 24 hours, in the majority of cases in which a natural water has a corrosive action on the metal of a boiler, some indication will be given of the fact by this simple test. In the case of artificially softened waters, which contain a slight excess of lime (lime, sodium hydroxide or carbonate) it was found that when the alkali exceeded a certain amount, no corrosion whatever occurred, but that with small amounts of the action was equal in intensity to that of the unsoftened water. It was ascertained that the presence of hydrogen peroxide and carbon dioxide had no effect on the rate of corrosion. The corrosive action of the softened waters was less energetic in the dark, and this, together with the fact that the metal of a boiler soon becomes coated with incrustation, may explain why "pitting" is not universal where these waters are used.

L. Archbutt, in an addendum to the above, considers it to be possible that after all, carbon dioxide is the chief corrosive agent, the action of which is increased when a sufficient excess of alkali has been added. In this respect, it is necessary to show that distilled water freed from every trace of carbon dioxide and oxygen is more corrosive to iron when slightly alkaline, when no alkali has been added.—W. P. S.

Rubidium and Caesium; New Method of Preparing —. L. Hackspill. Comptes rend., 1905, 141, 106—7.

AN iron boat containing a mixture of fragments of metallic calcium and the chloride of the metal (previously

absolutely dry), is placed in one limb of a very flat glass which has a vertical tube fused on at the angle. The vertical tube is drawn off so as to be readily sealed to the blowpipe. The apparatus is rendered vacuum by the boat heated. Reaction is vigorous, and metallic rubidium or caesium is distilled off and is easily collected and sealed in the vertical tube. The process was found inapplicable to lithium, as that could not be distilled off from the boat. (J. T. D.)

Solids; Determination of the Chief Constituents of — J. E. Clennell. XXIII., page 860.

ENGLISH PATENTS.

Metals and Metallic Products; Annealing and Tempering — H. Krantschneider, Berlin. Eng. Pat. 14,479, July 27, 1904.
